WE GUARANTEE that of this issue 5,750 copies were printed; that of these 5,750 copies 4,128 were mailed to regular paid subscribers, 523 were provided for counter and news company sales, 268 were mailed to advertisers, 37 were mailed to employees and correspondents and 794 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 5,750—an average of 5,750 copies a month.

MARING ENGINEERING is a member of the Associated Business Papers, Inc. (A. B. P.), National Association of Periodical Publishers, Inc., New York Business Publishers' Association and the Audit Bureau of Circulations (A. B C.).

Requests for change of address should reach us two weeks before the date of the issue with which it is to go into effect. It is difficult, and often impossible to supply back numbers to replace those undelivered through failure to send advance notice. In sending us change of address, please be sure to send us your old address as well as the new one.

The Administration's Views Anticipated

CHAIRMAN LASKER of the Shipping Board may not always correctly reflect the views of the President, but as he prefaced his speech before the Association of Commerce at Milwaukee on December 13 with the statement that "it was my honored privilege to submit the manuscript of this address to President Harding, whose passion to see America successful on the ocean is second to none" it may be safely assumed that there is nothing in this speech that does not meet with the hearty approval of our Chief Executive.

With this in view, a comparison of Chairman Lasker's remarks relating to the "Arms Conference and the Merchant Marine" with the leading editorial in the December issue of MARINE ENGINEERING AND SHIPPING AGE, which was written over three weeks before Mr. Lasker delivered his speech, is most interesting, showing as it does an apparent endorsement of our views.

After praising the Limitations Conference "as one of the glorious jewels in the crown of American accomplishments" Mr. Lasker immediately proceeds with the following statement: "Granting that the 5-5-3 naval program, or some equivalent, be adopted and that we have a naval holiday for a term of years, the question of naval equality is not solved; because if in addition to the equalized navies any one nation possesses a merchant marine of convertible strength vastly beyond that of another nation, the nation possessing that added convertible merchant tonnage has the preponderance of naval power."

Compare the above with our December editorial which starts as follows: "We are in full accord with the principle of the limitation of armaments and the cessation of the mad race for naval supremacy in "capital ships" which in the end can only mean financial ruin for the nations involved. But as great sea battles were fought in the days of ancient Rome with wooden vessels propelled by oars, so could terrible conflicts be waged today with the giant ocean liners hastily equipped with aerial, chemical and submarine instruments of warfare too numerous to mention. America must not forget that the importance of England's and Japan's great fleets of ocean liners will increase in far greater than direct proportion to the number of warships scrapped."

Chairman Lasker, although depreciating the possibility of a war between this country and Great Britain, gave comparative figures showing the relative superiority of the British merchant marine for convertible purposes. He said, "taking into consideration passenger and cargo ships of 8,000 tons and over which represent the very cream of the merchant marine convertible for naval purposes, Great Britain possesses 234 ships of this type already completed and the United States possesses 54 ships, a ratio of 4.3 to 1 in favor of Great Britain. Taking into consideration vessels of this type now actually building in both countries, the ratio in favor of Great Britain will be increased to 5 to 1."

MARINE ENGINEERING AND SHIPPING AGE has repeatedly advocated the reconditioning of the ex-German liners and the construction of new passenger ships. We do not expect war but we do know that it is easier to respect a nation that is an equal in strength than one that is comparatively impotent. It will be a wonder indeed if everything goes along smoothly in the future and this country having no axes to grind, no territory that it wishes to acquire, will be lax in its duty to the world if it suffers its naval strength to fall to any such standard as 1 to 5. We must rank somewhere near as equal in strength in our convertible merchant marine to other countries in order that our passion for peace may not be jeopardized.

But that is not all, for there are at least thirteen good and sufficient commercial reasons why we should balance our fleet unless we intend to scrap our cargo ships. No one denies that the freight rates are now too low to offer a sufficient inducement for capital to invest in shipping but, on the other

hand, there has been no reduction in first class passenger fares. It is safe to say that the *Olympic* has been netting over two hundred thousand dollars a round trip up to November and that the *George Washington* on one trip, at least, gave a profit of $100,000. The naval architect of one of our steamship lines shows on page 7 of this issue what could be done with the *Agamemnon* and *Mount Vernon,* if they were properly reconditioned. Wake up America! for what is done during the coming year will probably determine whether or not "Old Glory" shall take its proper place on the "seven seas."

Lightships and Lighthouse Tenders

SECRETARY HOOVER in his annual report emphasizes the immediate need for an appropriation for the construction of sixteen new lightships and eleven lighthouse tenders. As it takes from two to three years to get these vessels into commission after an appropriation is made, the urgency of prompt action on this matter cannot be too strongly advocated.

The report gives us the astounding information that twelve of the lightships are over fifty years old and that the average age at the present time of the lighthouse tenders is twenty-one years and the light vessels thirty years. There are now in active use nineteen lighthouse tenders that are over twenty-five years old and twenty-three lightships that are over thirty years old. Of course this deplorable condition is largely due to the concentration on merchant work during the war but, aside from this, there has been a large increase, amounting to 40 percent, in the number of aids to navigation that have to be maintained.

There can be no question of the necessity and importance of the work that the Lighthouse Service is doing in safeguarding both life and property. The loss of one ocean liner through a breakdown in this service would more than offset in property value, to say nothing of the loss of lives, the entire cost of the twenty-seven vessels that are urgently needed. Sooner or later such a catastrophe is bound to occur, if we continue to rely on these antique ships to perform the extra hazardous duty and to navigate in the shoal waters that this service requires.

That this department of the government has continued to function efficiently in the face of such a handicap in equipment must be credited to a splendid personnel, and it is therefore all the more shameful to require the officers and crews to continue to risk their lives in these old vessels which navigate in waters that every other ship takes good care to avoid.

However, from a practical business point of view there is no advantage in retaining in service any vessel after it has reached a reasonable limit of usefulness. There is a greatly diminished output of work and a rapidly increasing cost of upkeep and operation. The cost of repairs and the continual overhauling are sufficient reasons to construct new vessels, but when we have added to this the fact that the shipyards are anxious and willing to build these vessels at much lower prices than it has been possible to obtain for years, or are likely to occur again, there is nothing to be gained by waiting for a serious accident to stir us into action.

Ship Breaking

ONE of the immediate results of the Disarmament Conference will be the starting of a new industry in this country which in England is called ship breaking. It is estimated that there are between 400,000 and 500,000 tons of warships that must be scrapped and the problem is to salvage the material, machinery and equipment contained in these vessels. If this can be done successfully, there are millions of tons of obsolete and inefficient merchant ships which must, sooner or later, either be scrapped or taken out on the ocean and sunk.

However, without reference to the merchant vessels and relating solely to specific warships, a conference under the auspices of the Navy Department was held at the League Island Navy Yard, Philadelphia, on December 16. Representatives from shipyards, steel companies, scrap dealers, financial organizations, the Navy Department and trade papers attended. It was hoped that the conference would bring out a discussion of the national importance of the problem and the desirability of establishing ship breaking concerns in this country but no one volunteered any information of a nature that gave any light on the financial possibilities of the business.

Mr. J. G. Hitner of Philadelphia did say that he had been engaged in this line of work for several years and had been successful at it. He recommended that the Navy Department should require a high enough deposit from the bidders to eliminate all but reliable concerns and that it would not be fair for a company to submit the amount that it was willing to pay for a ship and thus expose its hand unless the highest bid was accepted whether or not it fell below what the Navy Department considered the ship was worth.

Representatives from companies which produce gas for cutting stated that there would be no trouble in cutting through armor but did not give any figures upon which estimates could be made. The whole meeting gave one the impression that while everyone was interested nobody had any intention of giving any information that could be of possible use to a competitor.

The presence, however, of shipyard representatives suggested possibilities for the utilization of plants where the equipment used in erecting a ship might also be used efficiently to break it up. Shipyards located in districts where transportation of the salvaged material to the market would not be too high should, with the equipment at their command, be in a far better position to handle this work than a dealer in scrap metals.

The question is, are the ships to be stripped of their brass fittings and such equipment as may be easily removed and then towed out to sea and sunk or are they to be salvaged to the greatest possible extent, even to cutting them to pieces with the gas flame? There are several thousand tons of structural steel in a ship of ordinary size. Is it possible for a yard with the proper equipment to break up this material cheaply enough to make it profitable as a business proposition? If it is, then we should not overlook the possibilities of the ship breaking industry, for there are millions of tons of vessels afloat today which should be broken up.

The Future of Our Merchant Marine

Restored Normal Prosperity in America Must Be Based on Foreign Trade and We Can Not Rely on Others to Carry Our Products

By "Old Scotch"

OUR ocean shipping, our shipbuilding and all our allied interests are in a very critical position. Never before in our history have these industries, so vital to our national well-being, faced such a dark outlook as at present.

Those requirements for the Jones law, which are supposed to be ample to protect our foreign shipping from the relentless rivalry of other nations, are not to be enforced. The reasons given by our executive for his failure to enforce these sections intended to establish our merchant marine permanently are evidently sufficient to his mind to warrant his declining to act, although it is strange, according to his own statement, that the much dreaded retaliation has not been even hinted at officially by any of the interested nations. Possibly it is due to causes with which it is not advisable to acquaint the public. Hence relying on his already demonstrated intensely patriotic interest in our merchant marine, it will avail naught to carry the inquiry further. What, then, awaits us? What hopes have we who with abiding faith have looked confidently to the future renaissance of our merchant marine?

A Straight Subsidy

In an article appearing in this magazine one year ago, the writer then expressed himself that after all is said and done the one sure remedy for our shipping ills is a straight-out subsidy, or, as Chairman Lasker recently expressed it in a public utterance, "a subsidy without synonym."

The President has already stated that early in January he will make a special appeal to Congress for a sufficient subsidy to enable private owners to operate our ships in the open rivalry on the seas. It is entirely unnecessary to try and convince the readers of this magazine of the national benefit of a subsidy to our ships in the foreign trade. Every one connected either directly or indirectly with shipbuilding or ship operating knows full well that it must come to pass, else our hopes and ambitions on the seas will perish ignobly. It is therefore the duty of each and all of us, who are thus interested, to constitute himself as a merchant marine evangelist and by every means possible and at every opportunity to preach the doctrine of governmental aid to those who are ignorant of the benefits of a nation's shipping to the general well being of all. In the offices, the shops, the railroads, the clubs and in the highways and byways, wherever you find a citizen and a voter needing enlightenment on this all-absorbing topic, go at him with an array of facts and arguments, so that he too will become enlightened and interested. The campaign must be intensive and far reaching. Do not overlook anyone; the further they live from the seacoasts, the more intensive should be *your* efforts.

President to Recommend Method

The executive has promised that he will endeavor to recommend a method whereby the money necessary to carry out his ideas will not be taken directly from the pockets of the already sorely tried taxpayer. Let us hope that the methods recommended will be such, as we know from past history of similar endeavors that anything which savors of governmental help to any particular industry will have a rocky road to fruition. The average congressman or senator looks askance at any such proposal and it is only the pressure from their constituents which will gain their support. It is well, therefore, for those of us who are interested to rehearse and fortify our arguments, which we know full well are logical and just.

In the writer's opinion the whole subject should be approached on the broad lines that a subsidy is another form of a protective tariff, no more and no less. In a new country such as ours, possessed by divine grace of enormous natural resources in field, forest and mine, it was but natural that in our early days we devoted ourselves to agricultural and mining pursuits and received our manufactured goods from the lands of our forebears, where, through the centuries of their development, such branches of industry had become thoroughly and efficiently established.

As our nation grew, and huge centers of population developed, many of our citizens began to look for a livelihood to sources other than those of the established elementary vocations. Whatever your politics may be, you must admit, as history has proven, that the great manufacturing interests which we now possess have been made possible by adopting the principles of the protective tariff in the earlier stages of development. The pioneers in any branch of manufacturing were confronted by lack of experience and by the higher standards of living which had, owing to our great national resources, become fixed in our customs. Almost any of the long list of goods, which our factories and mills now produce so successfully, would have been impossible of production here if the pioneers had been compelled to produce them in open competition with the long established plants in Europe. The 3,000 miles of water which intervened was in itself a barrier directly in proportion to the fluctuating costs of ocean freights, but that in itself was by no means sufficient.

Hence, in many instances protective tariffs ofttimes as high as 40 to 50 percent were established to aid these infant industries. As they gradually developed, and American skill and enterprise were applied to the methods of manufacture, many of the most important of them have reached a position whereby it is possible to produce the goods at home, without the necessity for any tariff to protect them. Notably among these is the great steel industry, developed from nothing until today we manufacture more of that highly essential product than all the other nations of the world combined.

Our Foreign Shipping an Infant Industry

Our shipping in the foreign trade today is an infant industry, exposed to the most intense rivalry of other nations, strongly entrenched by many years of experience and having much lower standards of living with consequent lower costs of operation. It does not even have the benefit of the protection of 3,000 miles and more of water surrounding our continent, for just one league from our shores the ships of all the world have an equality of opportunity. Basically and naturally, therefore, our shipping in its present early state of development must have the benefit of governmental protection, as all our other great manufacturing industries have had. A subsidy to ships is the indirect and only way of effectively applying the principle of a protective tariff on the seas.

Why is it necessary to have our own ships, and why not let foreigners, who specialize in sea-carrying and can do it for

less than ourselves, have the business, asks the unthinking?

The same inquiry could have been, and probably was, made concerning the steel industry, the tin-plate industry, the clothing industry or in fact any of our industries other than agricultural or mining pursuits.

The answer to any of these questions might be: Very well, if we all want to be and can be miners, farmers or lumbermen let foreigners do all of these things.

But we have reached a state in our national development where our manufacturing output exceeds our agricultural output. Further, we are producing much more manufactured products and farm products than we consume among ourselves. No business is successful unless it sells all its output. If Henry Ford manufactured 1,000,000 of his justly famous "flivvers" every year, and could only sell 850,000 of them and annually had 150,000 left on his hands, he would soon be a bankrupt and would not be figuring on buying railroads and nitrate plants.

In other words, we have to export our surplus products, amounting to 15 percent of our output in factory, farm and mine to be successful as a nation. To prevent our "flivvering" as a nation, these surplus products must be transported over the water and sold to other nations. Many of these other nations have excess products of the same kinds which they too must sell across the waters and what is more, they have their own ships in which to carry them.

Foreign Ships Will Give Preference to Their Own Products

Now, let us presume that our generous rivals will be glad to carry our goods to these same markets, where they wish to sell their own products in competition. You can have one guess, as that is all that is necessary, as to whose goods will be sold first. Just now, in this period of depression, if some magnate in Madagascar or other outlying place should even indicate that he wanted to buy ten locomotives, or a 1,000 tons of wheat, he would be deluged with offers. If we had no ships of our own, who do you imagine would get these orders?

It is all very well for foreigners to cut rates for carrying our goods overseas, when they know we have our own ships in which to make deliveries, but suppose again we had no ships of our own, what do you suppose the rates would then be, when it came to competitive selling overseas?

Merchant Marine a National Asset

A good, large merchant marine with all that goes with it would be a national asset, even if all our vessels were tied up to wharves or at anchor in our own ports in readiness to be operated. It would be worth millions of the public funds to protect us in our endeavor to dispose of our surplusage.

Having ships of our own is like having money in the bank. If a man has a good bank account, he can borrow funds very readily, but if he goes broke, no one will even look at him when he needs more funds.

Fifty years ago our foreign rivals had to have our food and minerals, but they do not have to buy our manufactured products and our farm products today, unless we make it attractive to them to buy from us. Hence every citizen of this country is either directly or indirectly interested in the maintenance of our own delivery system, exemplified by our sea-going merchant ships.

Now, how can this necessary subsidy be paid without further crimping the taxpayer's pocket? The answer seems simple enough.

During the late war and immediately following it, we spent about three and a half billions of dollars to create an enormous fleet of ships as a necessity of the times. In the minds of the public that sum has been marked off, along with the billions spent for battleships, ammunition, pay of soldiers and salaries and other sacrifices to the demon war. We were drunk and now we are going through the morning after.

Sell the Ships with a Subsidy

We could not sell these merchant ships today for much more than a half billion dollars, if that much, because under existing conditions it is not profitable for private owners to operate them under the American flag. If Congress grants a subsidy of say $50,000,000 as a protective tariff to our shipping industry, the sale value of the fleet would be doubled. Therefore sell the ships and out of the money obtained (already charged off in the minds of the public) pay the subsidy.

At first glance it looks like a bootstrap proposition, but think it over; the more you think about it, the better it will look to you. Keep also in mind the steel industry in this country, and of how by American methods it has progressed in a comparatively short time to a position where it no longer has to be coddled.

No shipping, no shipyards, is axiomatic. Therefore it behooves us all in either of these industries to get busy with our arguments for this subsidy legislation. We must succeed, or else we had better begin to study agriculture, and I know that shipping men make poor farmers.

Twelve Percent Increase of America's Merchant Marine Reported by Commissioner of Navigation

The annual report of the Commissioner of Navigation shows that on June 30, 1921, the American merchant marine comprised 28,012 vessels of all kinds of 18,282,136 gross tons, an increase over the preceding fiscal year of 1,958,114 gross tons, or 12 percent.

Of this amount 5,951 vessels of 11,077,398 gross tons were in the foreign trade, 21,478 vessels of 7,163,136 gross tons were in the coasting trade, and 583 vessels of 41,602 gross tons in the fisheries. The tonnage of vessels registered for the foreign trade is almost eleven times larger than in 1914.

There were 1,361 vessels of 2,265,115 gross tons built, 380 vessels of 183,209 gross tons lost and 212 vessels of 116,572 gross tons sold to alien flags during the year.

It is interesting to note that the average gross tonnage of a merchant vessel in 1868 was 154, in 1920 it was 579, and in 1921 it was 652.

The number of officers, below the grade of master, and seamen shipped and reshipped on American vessels by shipping commissioners was 325,832, of which 48.3 percent was American. The total number shipped, reshipped and discharged by shipping commissioners and collectors of customs was 707,206.

The use of radio on American vessels has increased rapidly since 1914, when there were 555 vessels equipped, compared with 2,978 in 1921, an increase of 437 percent.

The total number of radio stations of all kinds, with the exception of amateur receiving stations which are not required to be licensed, was 10,355 in 1920 and 12,258 in 1921.

Steamboat Inspection Service Activities.—During the fiscal year ended June 30, 1921, the Steamboat Inspection Service inspected and certificated 8,095 vessels with a total gross tonnage of 16,231,001, of which 7,753 were domestic vessels with a total gross tonnage of 13,139,630, and 342 were foreign passenger steam vessels with a total gross tonnage of 3,091,971. Of the domestic vessels, there were 6,437 steam vessels, 716 motor vessels, 15 passenger barges, and 585 seagoing barges.

Great Britain and Her Subsidies

A Lesson for the Law Makers of the United States—America's Need for Subsidized Shipping

By Winthrop L. Marvin

ONLY in the United States are shipping subsidies ever debated. Elsewhere they are accepted as a matter of course. A dozen years ago $47,000,000 was being annually expended by the nations on the fostering of their merchant marines. Now the sum is unquestionably greater. The imperative need of merchant ships and seamen has been a thought indelibly burned into human consciousness by the great world war.

Of this $47,000,000 expended for shipping subsidies by the nations of the world in 1909 and the years immediately thereafter, about $1,000,000 in a few postal contracts was the contribution of the United States. The richest of all countries was giving less to its merchant marine in this way than Canada ($1,581,000), one-third as much as Spain ($3,150,000), less than one-third as much as Italy ($3,872,000), and less than one-fifth as much as Japan ($5,413,000). France was then paying $13,423,000 a year in subsidies and Great Britain and her colonies nearly $10,000,000. It is Great Britain that has made the first and most successful use of shipping subsidies—and that notwithstanding their obvious conflict with her contemporaneous policy of free trade, now being quietly abandoned.

Cunard Line Created by Postal Bounty

British ocean subsidizing dates back more than eighty years to the postal bounty of $425,000 a year, which in 1839 created the Cunard line of transatlantic steamers. There quickly followed other and larger subsidies to the Peninsular and Oriental, the Royal Mail, the Pacific Steam Navigation Company and other new services to all quarters of the world. These early British subsidies did more than merely to create and sustain steamship communication. They contributed powerfully to the aid and development of steamship building and engine building in the era when the art was new. These subsidies were paid to liners when all steamships were liners, but after a while the shipyards which the subsidies had fostered were launching "tramps"—for it is the unfailing experience with liner subsidies that they develop commerce, which soon demands slower and cheaper cargo vessels for the carrying of its cheaper and bulkier cargoes.

Great Britain never made a more profitable investment than her several hundred million dollars of steamship subsidies from 1839 to 1921. These subsidies put behind the Cunard and other British steamship services of that kind the entire power of the Imperial government and made British steam shipping the most effectively protected industry in existence.

The Early British Subsidies

It is well for Americans, facing the same problem that confronted their kinsmen so many years ago, to take some note of the character and purpose of those earlier British subsidies. These are clearly and authoritatively stated by the Parliamentary Committee on Ocean Mail Contracts, through which British subsidies were first extended. Those lawgivers of 1840-1850, who framed the contracts and perfectly understood their nature, declared:

> "The objects which have led to the formation of these contracts and to the large expenditures involved were to afford us rapid, frequent and punctual communication with distant ports which feed the main arteries of British commerce and with the most important of our foreign possessions, to foster maritime enterprise and to encourage the production of a superior class of vessels which would promote the commerce and wealth of the nation in time of peace and assist in defending its shores against hostile aggression."

Merely substituting "American" for "British," President Harding might well cite these words of the Parliamentary Committee defining the character and purpose of British subsidies as the preamble of his shipping bill of 1921!

In 1909, and in the other years just before the world war began, British postal and admiralty subsidies to steam lines, retainers to naval reserve officers and men and similar assistance to merchant shipping amounted to a very substantial encouragement to shipbuilding and navigation. "In effect the Admiralty contracts," declared the report* of the British Tariff Commission in 1909, "constitute a rigid system of protection," particularly "to the British engineering and shipbuilding industry." And again, quoting from this same authoritative report, "Engineering and shipbuilding derive other considerable advantages from Government subsidies and Government mail transport and other contracts given to various British shipping lines. During the past ten years the government money which has passed into the hands of British steamship companies in respect of these and similar services has amounted to nearly £2,000,000 per annum."

It was with the historic facts about British steamship subsidies in mind that Mr. Blaine, in his celebrated debate over free trade and protection with Mr. Gladstone, declared:

> "It will not escape Mr. Gladstone's keen observation that British interests in navigation flourish with less rivalry and have increased in greater proportion than any other of the great interests of the United Kingdom. I ask his candid admission that it is the one interest which England has protected steadily and determinedly, regardless of consistency and regardless of expense. Nor will Mr. Gladstone fail to note that navigation is the weakest of the great interests in the United States, because it is the one which the National Government has consistently refused to protect!"

Mr. Gladstone never made any effort to reply to this—he could not answer. As one of his own contemporary public men, Henniker Heaton, Postmaster General of Great Britain, said:

> "As American ships were not subsidized, their owners could not compete with the Cunard and other companies, the art of shipbuilding languished, and the American carrying trade was transferred to foreign bottoms. In 1891 only 13 percent of the exports from the United States were carried in American ships, which at one time had engrossed 90 percent."

All this is historically true and accurate—and strikingly true and just also is the further declaration of the British Postmaster General that:

> "As a consequence of refusing $5,000,000 a year in subsidies during thirty years to native shipowners, or $150,000,000, the United States had to pay in the same period not less than $3,000,000,000 for freights, while their mercantile marine dwindled into insignificance."

American Subsidized Ships Led Their Competitors

So long as British subsidy was matched by American subsidy on the North Atlantic, the advantage was overwhelmingly in favor of the Stars and Stripes. Though the British had started with the first Cunard steamers in 1839, the granting of mail subsidies to the Collins and other American lines wrought an immediate and great increase in American steam shipping. As Lindsay, the historian of

*Volume 4, Paragraphs 91, 92.

British shipping, said, "Before the American line was established, the Cunard steamers were receiving £7 10s. per ton, freight, which was so much a monoply rate that in two years after the Collins Line had commenced the rate of freight fell to £4 per ton." Moreover, the American liners, with their larger size, higher speed and more comfortable service, quickly won the best passenger trade away from the Cunarders, to such an extent that between January and November of 1852 the American ships on the route between New York and Liverpool conveyed 4,306 cabin passengers to the 2,969 of the Cunard Line. In vain the British government increased the Cunard subsidy from $425,000 to $856,-000 a year. The American ships kept steadily ahead, holding all the Atlantic records and commanding the best and most profitable patronage. American ocean steam shipping rose from 5,631 tons in 1847 to 115,045 tons in 1855. As Dr. David A. Wells, the economist and historian, said:

"During the single year 1849-50 we increased our ocean steam tonnage one hundred and thirteen percent, and the seagoing qualities and performances of our vessels were so admirable that the Cunard Company, which had then been in operation ten years, was obliged to bring out new ships to compete with them. The prospect, therefore, at one time was that the United States, although late in the start in this new department of foreign shipping, would soon equal, if not overtake, her great commercial competitor."

American shipping subsidies, in other words, had proved far more effective and successful than British shipping subsidies while the two nations competed on approximately even terms. Two of the Collins steamers were lost because of the hazards of the sea. Several British transatlantic liners were also lost in the same period, the *President* and the *City of Glasgow* vanishing with all on board.

Withdrawal of Subsidies Killed the American Merchant Marine

But what killed the American transatlantic service, before the Civil War, was the withdrawal of the American subsidies in 1856 and in 1858 in the very crisis of the contest between the American and British flags. This action by Congress was due to the bitter animosities of the sectional quarrel preceding the Civil War. But for that ill-starred feud, which cost America so heavily, the Stars and Stripes would have continued to dominate the North Atlantic trade in steam as it long had under canvas.

Great Britain persisted in her subsidizing; the United States did not. That is the entire explanation, just as Postmaster General Heaton has described it, or, to quote the words of a great American shipowner and merchant, an eye-witness of the tragic change—A. A. Low, Esq., of New York, the father of Seth Low, once Mayor of New York and President of Columbia University:

"I only know the English have always, in peace and war, manifested a determination to hold the supremacy on the ocean, and the supremacy which they acquired by arms in war they have in peace acquired by subsidies. They have deliberately and intentionally driven the Americans from the ocean by paying subsidies which they knew our Congress would not pay. I believe it has been the deliberate purpose on the part of England to maintain her supremacy upon the ocean by paying larger subsidies than any other nation, as long as subsidies were necessary to preserve their control. . . . They have driven us from the ocean by that policy just as effectually as they ever did drive an enemy from the ocean by their guns."

History repeated itself in 1903, when, alarmed by the actual fact of German competition and a prospect of American competition also, the British Government gave to the Cunard Company an extraordinary grant of a subsidy of $1,100,000 for twenty years, coupled with a loan of $13,-000,000 at 2¾ percent interest which virtually made a present to the Cunard Line of the giant steamers *Mauretania* and *Lusitania*. This was at once the most liberal and the most valuable and effective subsidy ever given in the history of commerce. It was worth to the Cunard Company far more than its cash value—for it involved a declaration to the world that Great Britain would stand by her shipping lines, sustain them and see them through any crisis of competition whatsoever. Since that time the Cunard Company, gathering in other organizations, has become the chief of all British steamship companies—to all intents and purposes the British government afloat.

British Shipping Backed by the British Empire

It may be urged that it has not been the British policy to give subsidies or bounties to ordinary cargo steamers. But cargo steamers and liners have been in effect protected by the world-wide knowledge that the whole resources of the British Empire were at the call of the mercantile marine, and by the complete world-wide organization of British shipowners, agents, brokers, merchants and bankers, which provides a certain preference for British merchant ships, whether they be "tramps" or liners, in all the waters of the globe.

Neither America nor any other rival has any right to quarrel with British policies toward British shipping. They reflect prudence, patriotism and common sense. British statesmen have never been troubled by any little thing like dread of inconsistency. They have had free trade for manufacturing because they believed that it was to their advantage to have it. They have maintained protection through subsidy and in other ways for shipping because they knew that it best served their interests. They are heartily to be commended for so doing—and America will be commended if she has the wisdom and courage to follow the British example in administering vigorous protection wherever it is needed for the promotion of the United States merchant marine.

Subsidy for American Vessels Urgently Needed

America needs subsidy not only for her liners but for her cargo ships, because the most of the war-built tonnage of the Shipping Board consists of cargo ships pure and simple. As conditions now are, with the whole world over-steamered, these American cargo ships cannot be put into service and kept in service in competitive overseas trade unless, like the liners, they are also sustained by the protection of the Government of the United States. Cargo ships under our flag must have this protection because, assuming even the wisest amendment of the La Follette seamen's law, they must have compensation for their higher wage and living standards and costs of maintenance.

These higher costs are not due in any great degree to navigation laws and requirements—though so far as possible these navigation laws and regulations must be changed and modernized. These higher costs of American ship wages and maintenance existed long years before the enactment of the La Follette law. They would exist if that law were totally abolished. They are fundamentally due to the higher wages and standards of living that prevail among American workers on land, by which, and not by statutory law, sea wages and standards of living are established. There are the same reasons for protecting American cargo ships as there are for protecting American factories and farms—and the cogency of these reasons is not seriously questioned at any time by any considerable proportion of the American people.

Moreover, America is a country of heavy export cargoes. Its staple products of agriculture, mine and forest are relatively bulky materials. They demand and justify particularly the very active encouragement of cargo ships to convey them to the markets of the world.

With these conditions in mind there is no justification for withholding from our shipping the same protection that has given life and prosperity to our other industries.

Economics of Operating Reconditioned Liners

Figuring Revenues at a Minimum and Expenditures at a Maximum, the Mount Vernon and Agamemnon Could Be Operated at a Profit

By Carl E. Petersen

ONE hears so much nowadays concerning our inadequate representation in the North Atlantic passenger service coupled with the fact that a number of large ex-German liners are laid up at their docks after strenuous war service with no apparent definite policy as to their reconditioning and with few prospective buyers that it is thought that an estimate of the possible economics of two of these vessels, the *Mount Vernon* and the *Agamemnon,* would be interesting and a subject of profitable discussion.

These vessels, formerly the *Kronprinzessin Cecile* and *Kaiser Wilhelm II,* were for a time the largest and fastest passenger vessels in the transatlantic service and they had the reputation of being very profitable to their owners. Of course, it is realized that economic conditions with respect to steamship operation have changed greatly since pre-war times.

Particulars

Length over all	706 feet 6 inches
Length between perpendiculars	680 feet 4 inches
Breadth	72 feet 0 inches
Depth	44 feet 2 inches
Gross tonnage	19,503
Net tonnage	6,589
Mean draft	31 feet 6 inches
Average speed at sea, knots	22.4
Mean indicated horsepower	43,000

Service

For the purpose of these notes it is assumed that the vessels will be used to maintain a high speed transatlantic passenger, mail and express cargo service between New York and Bremen via Plymouth and Cherbourg.

Fuel

While these vessels at present use coal for fuel it is well recognized that in vessels of this size, type and power the additional operating expense, principally due to the larger fire room personnel required, delays in coaling, together with a loss in passenger space, would preclude the use of coal for fuel from an economic viewpoint. The use of oil as fuel would also increase the revenue from mails and express cargo and it would have the advantage of cleanliness. Therefore, the conversion from coal to oil is included in the total estimated cost of reconditioning.

To maintain an average speed of 22 knots and allowing 1.1 pounds of oil per indicated horsepower hour the fuel consumption per day would be 510 tons or not quite one ton per mile. Figuring the voyage one way at 3,900 nautical miles and allowing six lay days in port at 40 tons per day it will be seen that 4,140 tons of fuel are required. This capacity can be obtained in these vessels in the arrangement which at one time was contemplated. Fuel oil delivered is figured at $15 per ton or about 30 percent higher than the prevailing price at New York to allow for the higher price in Europe.

Passengers

Passenger revenue is based on a 75 percent capacity of 680 first class, 330 second class and 620 third class figured at minimum rates of each class, viz., $275 and $250 for first class high and low seasons, respectively, and $140 for second class and $103 for the third. When it is considered that previous to the war the demand for passage on these vessels exceeded the accommodations during the high season by 33 percent and equalled 75 percent of the capacity during the low season, the percentage used for an estimate is moderate. With excellent accommodations for all classes, equal or superior to competitive vessels, actual rates will exceed the minimum ones. No revenues from bar sales, steamer chair hire, confectionery, etc., are included in this estimate.

All figures are based on 12 round trips per year maintaining a 28-day schedule with one month lay up during the winter for annual overhaul. This schedule will allow more than ample time in port and by reducing the stay in port 13 round trips per year could easily be made should it be desired.

Subsistence is figured at $2 each per diem for first class passengers, $1.50 each per diem for second class, and $1 each per diem for third class and crew.

Express Cargo and Mail

	Tons
Weight of ship light	20,000
Water in boilers	800
Fuel oil	4,140
Fresh and feed water	1,600
Passengers, crew and stores	415
Mail, 6,000 sacks at 50 pounds each	135
Express cargo	600
Displacement at 31 feet 6 inches mean draft	27,680

Express cargo is figured at a nominal figure of $10 per ton per trip. The actual revenue will be largely increased because it is customary to rate express cargo by the measurement ton and the cubic is available in these vessels. However, the figure given will suffice for an estimate.

Mail carried without special contract is usually conveyed eastbound at a rate of 80 cents a pound for letters and post cards and 8 cents a pound for other matter and westbound at about 35 cents and 4½ cents respectively. For the purpose of this estimate mail is figured roughly at $5 per sack eastbound and $2 per sack westbound, allowing 6,000 sacks eastbound and 1,000 sacks westbound.

Annual Revenue per Vessel

Passengers		
1st class 680—75%—@$275 x 13 one way trips	$1,823,500	
1st class 680—75%—@ 250 x 11 one way trips	1,402,500	
2d class 330—75%—@ 140 x 24 one way trips	831,500	
3d class 620—75%—@ 103 x 24 one way trips	1,149,500	
	$5,207,000	$5,207,000
Mail		
6,000 sacks @ $5 x 13 one way trips	$ 390,000	
1,000 sacks @ 2 x 11 one way trips	22,000	
	$ 412,000	412,000
Express Cargo		
600 tons @ $10 x 24 one way trips	$ 144,000	144,000
Gross revenue		$5,763,000

Annual Expenditures per Vessel

Fuel—99,600 tons oil @ $15	$1,494,000	
Wages, officers and crew	453,500	
Feeding passengers and crew	512,500	
Equipment, water, lubrication and stores	165,000	
Repairs	240,000	
Insurance	90,000	
Rental of terminals, stevedoring and handling, port charges, towage, advertising, administrative, and sundries	980,000	
Total expenditures		$3,935,000

Capital Expenditures

	S. S. Agamemnon Built 1902	S. S. Mount Vernon Built 1906
Purchase price "as is"	$ 800,000	$1,100,000
Cost to recondition	2,200,000	2,000,000
Capital invested	$3,000,000	$3,100,000
Depreciation	600,000	344,000
Interest on investment, 6 percent	180,000	186,000
Capital charges	$ 780,000	$ 530,000
Gross revenue	$5,763,000	$5,763,000
Gross expenditures and capital charges	4,715,000	4,465,000
Balance after deducting expenditure and capital charges	$1,048,000	$1,298,000

Depreciation

Depreciation is charged off in this estimate at a flat rate of 20 percent and 11.1 percent yearly for the *Agamemnon* and *Mount Vernon*, respectively, for the reason that the prudent steamship owner would no doubt have the invested capital written off by the time the vessels are 25 years old. In this way rising costs of operation due to age could be offset by the absence of capital charges and the vessels show a profit for some years to come.

Interest

Interest on the investment is taken at 6 percent per annum on the decreasing book value of the capital invested.

Conclusion

Revenues are estimated at a minimum, expenditures at a maximum and reasonable factors and values are used throughout. From the estimated balance it will be seen that the reconditioning and profitable operation of these vessels is not a hopeless proposition. The fact that passenger fares have remained at the peak while freight rates have scraped the bottom shows that the supply is not greater than the demand as far as passenger ships are concerned. It would seem that a million dollar profit per annum on an investment of $3,000,000 in the most stable department of ship operation would attract the attention of even the conservative element of the investing public.

American Ships Now Operating on Economical Basis

Experienced Ship Operator Outlines Savings Already Accomplished—Overhead, Stevedoring, Manning Schedules, Wages and Subsistence Reduced

By Robert E. Annin

WHETHER freights have reached bottom at present or whether they are destined to go still lower may be a matter of opinion. Surface indications point to at least the *relative* maintenance of the present level of rates, i. e., that freights can only decline further, if, and when, a decline in the level of operating costs shall have become established. The progressive and worldwide laying up of tonnage clearly indicates that (at least under present cost scales) the operating dead-line has been reached.

American operation has been the most expensive in the world, due to causes which have been thoroughly exploited and which it is not necessary to detail here. Some of these causes still persist and are likely to do so for some time. Others have been due to the inflated psychology of the years 1915 to 1920. This has affected all nations greatly; but has had, perhaps, a particularly marked effect here, owing to the greater proportion of new operators and the almost unlimited demands of American labor during the war emergency. A certain American impatience of small economies may also have been a special factor in our operating costs. In ship operation this latter factor would chiefly affect the inexperienced, since trained operators of every nation know the imperative need of the closest economies in every department of their business. In close competitive times there is no such thing as an "unimportant" economy.

Among the larger expenses of war time, the item of swelled salaries ashore was notable. When freights were at their peak, for instance, salaries of $10,000, $15,000 or $20,000 were not uncommonly paid by concerns which were operating only small squadrons; and every old organization found its personnel constantly threatened by the bidding of new "operators" for their most promising young men. All this, of course, reacted upon the whole salary level for department heads and managers; making the shore end of operation here enormously higher than abroad.

For minor positions (assistants, clerks, etc.), our level has always been much above the European; and this class of office workers profited largely by the inflation of the war and afterwards. Chiefly for these reasons, new and small organizations here frequently ran office expense schedules up to $100,000 or more per year—a scale of expense unknown in this class of firm abroad, even in the times of highest freights.

Shore Expenses of English Shipping Firm

In this connection, the yearly statement of an English shipowning company for the year 1920 seems quite pertinent and affords a striking contrast to the shore operation of many war-time concerns on this side.

The corporation in question showed capital and reserve of £700,000 and assets of about £1,050,000; indicating (on the basis of ruling values even at the end of 1920) a very modest fleet. The gross operating earnings were £145,000; a not surprising figure when the freights ruling in the early part of the year are considered. The main items against earnings were repairs and general maintenance of steamers, about £37,500; and an income tax of £39,000. But the most striking items in the statement are the following:

"To business expenses, including management and rent	£3,076/12/4
"Directors' fees	991/ 0/3
	£4,067/12/7

or say $16,000 shore expense for the management of $4,000,000 of shipping property—4/10 of one percent for shore management and under three percent of gross earnings for management and rent, including directors' fees. In the year 1920 it is a safe assertion that few firms of the same class in America were getting through on less than three times these figures. Of course the extravagant shore expense of the boom times is now a thing of the past. The high rents and salaries and the general disregard of economy, here and abroad, have stopped.

It was obvious from the first that, when the inevitable collapse should occur, such a condition would be the first to cure itself. The failure of some firms, the voluntary re-

tirement of others and the inevitable cutting down of office force by the remainder have already reduced salaries to something like a pre-war basis for all except absolutely essential men. This process is likely to continue until the men displaced by lack of business have had time to disperse into other occupations. The times when it was necessary to offer $12,000 to secure a $4,000 traffic man seem very far in the past, yet this was approximately the case a little over two years ago.

This has been the first great American economy introduced since the slump; it has come very close to being universally practiced, from stenographers to managers. It is not necessary to speak of partners and proprietors who find themselves living on their own savings, or in vulgar phrase, "sucking their paws."

In normal times the shipping business pays high salaries to only a very small proportion of office personnel; certainly not a larger proportion than other trades. Clerical aid earns no more money in shipping than a similar quality of service commands elsewhere. But during the boom freights the pay of every branch of service, afloat and ashore, showed an inflation that was simply staggering to oldtimers, trained in the economies of 1901-1910. Here, then, is one recent disadvantage of American operation that is rapidly lessening by mere force of economic pressure. The result is inevitably a very material reduction in the per ton cost of handling tonnage from the shore end. That is to say, the reduction of exaggerated salaries means an increased efficiency per unit of expense.

Loading and Discharging Costs Reduced 50 Percent

One might speak here of a similar improvement in conditions "along the beach," as relates to loading, discharging and wharf work. These were almost incredible at one time and certainly cast a valuable direct light upon the contention that high wages produce efficient service. Those whose duties called them to the wharves when wages were at the highest usually came away confirmed in the old conservative belief that such a contention merely confused cause and effect. Since the arrival of hard times, however, "the beach" has gone a long way back toward normal. With the decline in wages and increase of unemployment has come an increase of efficiency which has reduced loading and discharging costs by certainly over 50 percent. To the average man, the fear of losing his job is the only sure incentive to diligence and efficiency. This, however, so far as it concerns either American or foreign ports, applies to all ships equally and is therefore no *relative* gain as between rivals.

Turning to the marine department of operation, operators have been working most keenly, consistently and intelligently to reduce the admitted handicaps under which American ships have heretofore labored. Owing to causes generally recognized, ships privately owned have some advantages over those handled through Government agencies. It is therefore from the private owners that the most marked progress should be expected in important (and even vital) operating economies.

During the boom freights, and owing to the scarcity of efficient men in all ratings, the American ships carried a larger personnel than any rival except the Japanese. Our wage scale was also much higher. Hence, on the face of things, the American expense for wages and subsistence was enormously higher than that of foreign competitors, amounting at times to nearly double that of the English and Norwegians on vessels of the same class. In this result the depreciation of foreign currencies was the chief factor. A German ship (for instance) was reported arriving at Philadelphia last August, with the master drawing a wage of only 2,000 marks a month—then equal to $25.

The effect of this condition, added to others, was such that the American had either to retire from the competition (at least temporarily) or find some way by which his payroll might bear a reasonable relation to that of his chief rivals.

Temporary Withdrawal of American Ships

So far as the occasional business is concerned (i. e., tramp charters), it is evident that most American owners, including the Emergency Fleet Corporation, chose the first course. This is a fair inference from the fact that a leading freight broker's report (from September 1 to December 1, 1921) shows from American ports about 471 outward charters, of which only about 30 were American. (These figures are not necessarily exact but are sufficiently so for any use which is here made of them.) This is for business out of North American ports, excluding United States coastwise trade, which is, of course, protected.

Now, considering that a large part of tramps arriving here come in ballast *"seeking"* (for our deep-sea trade has never been a balanced one) it is clear that, if we can only retain six or seven percent of our business when our foreign rivals bear the waste of coming to us, we cannot hope for success, if we bear the waste of going to them, as for instance in attempting to compete for the export trade in English coal.

It seems therefore a fair statement, based on these facts and considerations, that the record of the past few months indicates the temporary withdrawal of American tonnage from the "full cargo" market.

There remain, however, the line services, private and Governmental (established, unestablished, and incubating), which cannot in the nature of the business withdraw and re-enter as conditions fluctuate. It is among these that we should look for the results of continuous consistent effort in operating economies aboard ship; and it is there, in fact, that we find the greatest progress in such direction.

Of these economies, in view of the inflated conditions from which we are now emerging, the payroll is among the most important. So far as higher ratings are concerned, every line operator strives to retain those licensed officers who have made good, knowing from experience that to keep changing this class of employees for the sake of any small immediate saving is one of the greatest of extravagances. Like every other human aggregation, licensed officers have their share of incompetents and worse. One of the tramp owners' great difficulties is the constant drift of the best officers toward the steadier and more permanent liner services. On the other hand, the line managements, by a continuous process of selection, have the opportunity to build up a personnel which may constitute a most valuable asset; and in pursuit of this purpose the line agent will avoid any policy which would, in the end, prejudice this result.

Selection of Efficient Officers

Under such circumstances no attempt to economize by laying off able officers is likely to result in permanent saving. But the process of selection is made more severe, the incompetent and careless more sternly weeded out and the efficiency thus reached, both on deck and in the engine room, constitutes in itself a most important and permanent economy. No longer need the owner put up with masters who are resourceless at sea and in port, or careless or unsatisfactory in the log books or accounts. The engineer who notoriously spends, personally, more money than he earns officially, and whose fuel accounts are inconsistent and suspicious, is remorselessly replaced by one who has not these eccentricities of genius. In this sense the surplus supply of licensed officers offers a great opportunity for the best and most permanent kind of economy, i. e., the selective upbuilding of an efficient personnel.

In the lower ratings, however, there is opportunity for direct economy both in numbers and pay. The average mer-

chant crew is partly composed of a restless and migratory class whose steadiness cannot be counted on from one voyage to the next, whose avocation is change of berth and whose chief outdoor sport is desertion. So far as this class is concerned no sacrifice of immediate economy to insure permanence is warranted except in the case of individuals.

As to wages, the excess supply of seamen has already greatly reduced payrolls from even last year's level. With bread and butter necessities staring them in the face, many sailors in the lower ratings will accept, and are now accepting, wages which would be very close to the English scale if sterling were at par. Reports of $60, $50 and even $40 berths accepted, for instance, by able seamen are not uncommon. In fact the market is a wide open one and the owner or agent may make what bargain he can with individual seamen. Even the needy trade unionist realizes that half a loaf is better than no bread in these times. So much for the wage situation, per se.

Manning Schedules

Further economies are now being practiced in the cutting down of personnel. An American ship which a year ago carried twelve able and ordinary seamen may now, perhaps, get along with eight; some which in 1920 had ten men and boys in the steward's department will now operate with six. The main difficulty a year ago, when labor was scarce, was that the men would not stand for extra work. Today they will. The saving of wages and subsistence for four seamen in the deck department and two messmen and one utility man in the steward's department may not have sounded very important during the high freight period, but in these days $400 per month in wages and subsistence from such an economy looks quite worth while.

In the engine room the cutting down of force is more difficult, partly because of the attempt to make the engine room force "100 percent American." In an open competition any limiting condition applied to one competitor and not to another is a handicap in reaching the nearest to ideal efficiency. It is *not* for nothing that the thrifty and economical Scot has a world wide reputation as a marine engineer. In the engine room, accounts show the greatest relative economies in personnel, stores, lubricants and, above all, bunkers.

Nevertheless, some of the most up-to-date operators now claim that as to number of personnel they can about match the English crew list on the average, i. e., so far as numbers go they are at no material disadvantage; where they were, only a year since, pulled down by wages and subsistence for five to nine extra men.

Economy in Port

Payroll economy may also be practiced in port whenever outward cargo is not in sight for an arriving ship. In such case the deck and steward's departments can be cut down to a caretaker's basis in the lower ratings. Reduction can sometimes be made in the engine room, but not always, and of course not to the same extent, the engines always requiring more attention, care and tuning up than any other part of the ship.

But deck and engine officers, recognizing the difficult situation of owners under present conditions, will often make special arrangements during a waiting period which materially reduces their pay while in port; a sort of "loss-sharing," which, however, is purely for an emergency. Such arrangement may be presumed to be confined to officers who feel secure of their positions and who, therefore, submit to a sacrifice of personal interest out of loyalty to their line. A sacrifice of this kind is likely to give them a special status for the future. In other words, such action, like most human action, may result from motives more or less mixed.

The matter of subsistence has necessarily received strict attention with marked effect. There is some difference between Kipling's mate of a Cardiff collier who would "eat clinker to save waste" and the post bellum table of a merchant foremast hand which ran into all sorts of excesses from broiling poultry to fruit out of season. The subsistence bills of merchant ships during the war and post-war boom were appalling even to the most inexperienced operators. The causes were partly war inflation, partly inexperienced operators and partly graft.

Cost of Subsistence

In 1913 an English owner expected to feed his crew at from 35 to 40 cents per day per man. In the winter of 1920-1921 the average cost on English ships ran up to $1 per head and of American $1.25, $1.50 and (as is reported in some cases) very much higher. From thence on there has been a steady decline in cost of subsistence on all ships and, as the American was most extravagant in this respect, the decline in American cost has been notably the greatest. From a per capita of at least $1.25 less than a year since, the price had reached $1 by June, 1921; 85 cents by August, and may now fairly be placed at an average of 60 cents. Reported present costs range from 65 cents down to 52 cents per capita, according to circumstances.

Detention of Ships in Port

FIGURES giving the average number of days spent in berth and the average number of days waiting berth by vessels engaged in foreign trade for certain of the large ports in Great Britain are published monthly by the British Board of Trade. From these reports are taken the figures tabulated below which refer to vessels dealt with at the accommodation of the Port Authority named.

By "working day" is meant a complete week day of 24 hours, Sundays and holidays being excluded and parts of a day being dropped. No distinction is made between a vessel which carries cargo only one way and one which both discharges and loads, nor as to the character of the cargo handled. It will be apparent from this that the figures are not comparable as between one port and another, but that within certain limits they are comparable between one month and another at individual ports.

Port and Name of Authority	Month 1921	Number of Ships Departing: Total	Average working days in berth per ship Days	Average delay per ship waiting berth Days
London	July	316	9.04	0.25
(Port of London Authority)	June	289	9.05	0.32

Railroad Contracts With Foreign Shipping Lines

By Waldon Fawcett

The exclusive or preferential contract between any railroad operating in the United States and any foreign flag shipping company is soon to become a relic of the past. This much may be confidently predicted as the result of a conference held at the offices of the United States Shipping Board in Washington, the first week in December. This conference between the representatives of ten leading American railroads and the Shipping Board Committee on Interstate Commerce Conferences, was the fruit of a spirit of resentment that has lately manifested itself in the Congress of the United States.

THAT element in the national legislature which has given unreservedly of its enthusiasm in behalf of the upbuilding of an American merchant marine was manifestly perturbed, not long since, when it came to the attention of Congress that there were in existence close compacts, or exclusive contracts, for reciprocity in the exchange of traffic between certain American railroad systems and various shipping companies operating vessels of foreign registry. There was animated discussion in the United States Senate as to the propriety of such entangling alliances, and ultimately the Senate "resolved," as it does when a matter of public policy or practice requires investigation.

All that will be necessary, however, to abolish existing international alliances of rail and water transportation interests and to prevent such arrangements in future is repressive action by the Shipping Board. By the terms of the Jones law, or the Merchant Marine Act of 1920, the Shipping Board is clothed with ample authority summarily to sunder the foreign connections of American railroads and this fact is fully appreciated by railroad executives. Indeed, some of the railroad men, moved by the spirit of patriotism or seeing the handwriting on the wall, had already taken steps to terminate existing contracts ere they journeyed to Washington to discuss the situation with the Shipping Board committee consisting of Frederick I. Thompson, of Alabama, chairman; E. C. Plummer, of Maine, and Meyer Lissner, of California.

Conference Has Dual Purpose

Dual purpose was ascribed to the conference. First, the Shipping Board commissioners would examine, by means of first-hand information, into the extent, character and effect of the railroad contracts with foreign shipping corporations. Unless, however, evidence of exceptional character was forthcoming the outcome was foreordained. The Shipping Board committee had devoted weeks of preliminary study to the subject and out of a close inspection of copies of all the contracts and the personal experiences and observations of the three commissioners had been borne a pretty strong conviction that, sentimentally and practically, the existence of such contracts was detrimental to the best interests and the future prospects of the new American merchant marine.

Second of the purposes of the conference was formally to ask of the railroad interests the abrogation or cancellation of these contracts that seem to bid defiance to an expanding merchant marine under the United States flag. It was this phase of the objective that necessarily rendered inconclusive the immediate outcome of the negotiations. There was manifest on the part of some of the railroad men a spirit of ready concurrence in the ideas and the wishes of the Shipping Board committee and on the part of the other railroad delegates the realization that the word of the Shipping Board is law in the premises. But a number of the railroad executives asked for time to consult with their directorates or fellow executives—not so much as to the fundamental act of renunciation as to ways and means of severing relations legally—and accordingly the conference adjourned to await the preparation of formal proposals on the part of the railroads. However, as has been said, whether the process be wholly voluntary or partly compulsory, the outcome is almost inevitable.

Exclusive Contracts Affect Development of Ports

Incidentally it was revealed in the course of the hearings that the Shipping Board committee which initiated the impending "reform" has in prospect a project of even deeper and more intimate significance to the shipping interests of the United States than the severance of foreign alliances. Chairman Thompson dropped the remark that, once this present problem is out of the way, the committee contemplates an investigation of all existing contracts and reciprocal arrangements between American railroads and American shipping interests. He was careful to make it clear that this impending issue is not to be allowed to becloud the current one but seemingly there is a suspicion that anything in the nature of exclusive contractual relations between rail and water lines may not only make impress upon the evolution of the merchant marine but might likewise exert influence upon the development of American ports and the provision of terminal facilities.

Ten American railroads are involved in the international "communities of interest" which the Shipping Board is so strongly inclined to regard as prejudicial to the free fighting chance of an American merchant marine. As shown by the records compiled by the Shipping Board committee the contract distribution covers both hemispheres. The Baltimore and Ohio Railroad has contracts with the Donaldson Lines, Scandinavian Lines and Furness, Withy and Company. It formerly had a contract with the North German Lloyd but this lapsed when the German service to the port of Baltimore was interrupted at the time of the world war. The Great Northern Railway has a contract with Nippon Yusen Kaisha —a contract that provoked the most spirited discussions of the conference owing to the fact that it was renewed in October, 1921, on the very eve, as it were, of the governmental move to bring about severance of relations.

The Pennsylvania Railroad has contracts with the International Mercantile Marine Company and the Pennsylvania's affiliated line, the Northern Central Railroad, has engagements with the International Mercantile Marine and Furness, Withy and Company. The Southern Railway Company and the Mobile and Ohio Railroad each have contracts with the Mobile Liners, Inc. The Boston & Albany Railroad is accredited with contracts with the Leland Steamship Lines and Cunard Steamship Company. The Chicago, Milwaukee and St. Paul Railway is affiliated with Osaka Shosen Kaisha. The Grand Trunk Railway System has pooled interests with the White Star Dominion Line and the Atlanta, Birmingham and Atlantic Railway has a compact with the Strachem Shipping Company.

Some Contracts Are not Harmful

For the most part these various commitments are ten-year contracts, with option of renewal. Most of them may be

cancelled upon six months' notice by either party or upon shorter notice by mutual consent. Before the Shipping Board committee went below the surface in its investigation, it was assumed that all the contracts were approximately on a par, insofar as effect upon American merchant marine interests might be concerned. It developed at the hearing, however, that there is a wide disparity in intent and influence. Some of the contracts seemingly offer no practical menace whatever to the American merchant marine. For example, the contracts of the Pennsylvania Railroad and the Northern Central with the International Mercantile Marine Company merely relate to the use of specific piers owned by the roads, a use not discriminatory against other shipping. Then again there is the case of the Grand Trunk contract with the White Star Dominion Line. It was brought out that the only purpose of this compact was to secure for the port of Portland, Me., during the winter months, traffic that is almost wholly of Canadian origin. It was predicted that the only effect of a rigid repressive policy in this quarter, at the behest of the Shipping Board, would be to drive traffic to Canadian ports with no compensatory advantage to either American ports or the American merchant marine.

Pursuing the subject, it might be added that one of the outstanding features of the Washington conference was the warning by railroad executives that the Shipping Board must, in its zeal to preempt the field for the American merchant marine, proceed cautiously lest it drive to Canadian ports transatlantic and transpacific traffic that the United States ports can ill afford to lose. This was the plaint in particular of W. P. Kenney, vice-president and director of traffic of the Great Northern Railway—an executive whose viewpoint was the more interesting because he was formerly the head of the Great Northern Steamship Company. Indeed, Mr. Kenney remarked at one point that the Great Northern has expended to date more money than has the United States Shipping Board to keep the American flag on the Pacific.

Danger of Diverting Cargo to Foreign Ports

Defending his company's contract with the Nippon Yusen Kaisha and its renewal in the face of the Government's concentration on the upbuilding of an American merchant marine, Mr. Kenney stressed the danger that Japanese ships be diverted to Canadian ports and Japanese cargoes be routed via Canadian transcontinental railroads to destinations in the eastern part of the United States. The Great Northern executive, reacting to the patriotic plea, took a fling at the numerous shippers in the United States who are routing their Oriental shipments via the Canadian Pacific to the coast and thence via Canadian ships to the Far East. And he had something to say regarding the Dollar line of steamers which, upon passage of the La Follette Act, sought a Canadian port and alien registry and which, Mr. Kenney declared, now gets more tonnage from the United States than does any American line on the same route.

Throughout the discussion the traffic director of the Great Northern maintained that he had renewed his contract with the Japanese line so recently as October, 1921, simply because he felt that, if there was in the compact anything antagonistic to American public policy, the Shipping Board had ample authority to nullify the agreement. It was difficult, however, for the Shipping Board commissioners to sympathize with this viewpoint. Chairman Thompson said earnestly that he felt that the principle was inescapable that the Great Northern had, by this contract renewal, gone into direct competition with the Government in its effort to establish a merchant marine, at the very moment when the Government thought that it had assurance of the cooperation of all agencies. The commissioners felt especially aggrieved that the Great Northern had not even conferred with the Government before renewing its contract, albeit the Government has on the Pacific a service comparable with the Japanese and is planning to place five fast steamers in the Seattle service, even though it be necessary to operate these at a loss as the ships on this route have been operated at a loss in the recent past.

Cannot Influence Shippers Beyond Their Own Lines

With varying degrees of emphasis the railroad executives who demurred at cancellations of their contracts with foreign shipping interests pivoted their justification on one outstanding radical premise. This theory was that American railroads benefit individually from foreign shipping contracts by allocation of incoming tonnage but, because of a lack of ability to dictate as to the disposition of outbound tonnage, are unable to do any harm to American shipping. It was a bald assumption that the contracts are in distribution of benefits, decidedly one-sided, or that the American railroad has, as one spokesman put it, "the long end of it."

To support such a theory requires, of course, a daring logic. The railroad men had it ready to hand in the contention that, under present conditions, an American railroad —no matter how keen it may be to throw business to an affiliated shipping interest (American or foreign)—is unable to influence shippers as to routes or carriers beyond its own lines, save in rare instances. Control has been taken from the railroads in the routing of this overseas business according to this school of thought. In proof of it, Traffic Director Kenney of the Great Northern Railway pointed out how his road's Japanese shipping ally was first chagrined and then incensed at the inability of the Great Northern to turn over its traffic bound beyond the Pacific and how finally the Nippon Yusen Kaisha, facing the inevitable, had been compelled to build up its own freight soliciting organization in the United States until today the Japanese line has in New York, Chicago and other traffic centers larger organizations than the Great Northern itself maintains.

Relation of Inbound and Outbound Traffic

That theory which assumes that the railroads are able to secure, through the intervention of foreign shipping interests, a worthwhile aggregate of inbound tonnage without repaying in kind was only equalled in interest in the presentation at the conference by the plea that American railroads are capable of maintaining alliances with foreign shipping lines without giving to the latter any special concessions or any treatment preferential in any way to that vouchsafed to all other lines, including, of course, the American flag lines with which there are no such special contractual relations. The leading exponent of this theory at the conference was Mr. Archibald Fries, vice-president in charge of traffic, Baltimore and Ohio Railroad. The Baltimore and Ohio executive insisted that the contracts of his line with British and Scandinavian shipping companies, as above enumerated, do not beget for these connections any service or privileges not given to more than a score of other lines (American and foreign) that dock at the Locust Point piers of the Baltimore and Ohio.

It was explained by the Shipping Board commissioners that the objectionable element in contracts such as have been entered into by the Baltimore and Ohio with foreign lines lies in the grant of free use of piers and in the promise on the part of the railroad company to use its "best endeavors" to promote the business of the affiliated line. This precipitated quite a discussion as to the precise meaning of the term "best endeavors" but the representative of the Baltimore & Ohio insisted that both his principals and the foreign shipping companies and their agents understood that the contracts assumed that there was to be no discrimination for or against any line. In answer to a question as to how, in the face of the "best endeavors" clause, the Baltimore & Ohio

(*Concluded on page 22.*)

Developments in Marine Insurance

Lake Underwriting Experience—Deck Loads—Government Threat—Court Decisions—Builder's Risks—The Tanamo

By "Bordereaux"

NAVIGATION on the Great Lakes has closed for another season, and in the opinion of underwriters it has been a period of unusual experiences. The world-wide slump in shipping has been felt very keenly on the Lakes; October and November, in particular, were two of the very dullest months in freight ever on record in that region. During the entire season the movement in ore, which comprises one of the two largest commodities shipped over the Lakes, was extremely dull, due to slack business in the steel and copper industries. Up to November 1 only 22,087,786 tons of ore had been shipped eastbound over the Lakes, as compared with 50,951,942 tons for a like period of 1920. Ordinarily there is a rush of shipments as the close of the season approaches, but this year the offerings were far below those of previous years. Grain, on the other hand, moved in considerable volume throughout the year and was rushed forward in numerous ship loads as the final day of navigation drew near. Total shipments for the season exceeded 200,000,000 bushels, which is an increase over the movement of this commodity in 1920 by close to forty percent. The reason lies in the low price of grain, creating a large demand from abroad; but a late sharp decline in the foreign demand resulted in a glut of grain at Atlantic ports and the resultant employment as storage warehouses of vessels laid up for the winter. The charge for insurance on values so stored is about two-thirds of a cent per $100 per day—a practice that has been in active vogue for years, the lake marine policy carrying a regular winter storage clause to this effect.

The usual exciting scenes were again enacted at Lake ports as the hour for the close of navigation approached. Twenty steamers were rushed out of Fort William, Ont., in twelve hours, carrying more than $7,000,000 worth of grain. The last vessel to get away and take advantage of the lower insurance rates beat the clock by the narrow margin of only fifteen minutes.

Navigation on the Great Lakes, by the insurance schedule, covers about two hundred and fifty days, the actual period depending upon ice conditions during April and December. In an open season navigation often continues as late as December 20, but as the lighthouses and other aids to navigation are not in operation after the sixteenth of the latter month, vessels find it difficult to procure insurance for sailings from the head of the Lakes after the twelfth. Hull policies permit of navigation up to December 1 at the policy rate, with additional sailings granted up to December 12 at heavily increased quotations subsequent to the first.

On the whole, hull insurance experience on the Lakes has been favorable throughout the season; but cargo premiums have fallen off. Low water during the last few weeks of the season was responsible for numerous strandings, and after the severe storm in early November the water level at the lower end of Lake Erie became so low that many groundings occurred and vessels drawing more than fourteen feet were not allowed to enter the Welland Canal. It is expected that next year will see a return to almost normal activity on the Lakes, as many of the vessels that during the war were brought down to the Atlantic coast have returned in answer to the demand of the grain movement for boats that can pass through the Welland Canal to Montreal and to the sea.

Regulating Deck Loads

SHIPOWNERS and operators will find much to interest them in the model rules proposed in the Hague Rules, 1921, designed to guard against the disastrous consequences of excessive deck loads. Insurers are conscious of the enhanced hazards involved in stowing five percent or more of a cargo above the weather deck, and they are convinced that the carriers know of the added dangers but take chances for the sake of more freight. Several resolutions were devised by the conferees at the Hague, covering the point, and they are urging their several Governments to give them legislative support to the end that there may be a decrease in shipping casualties caused primarily by the overloading of decks. Following are the Hague resolutions:

(1) That all ships which carry deck cargoes exceeding 5 percent of their total deadweight capacity should have a certificate indicating their fitness to carry such deck cargoes.

(2) That a uniform system of issuing certificates of fitness should be adopted by the various maritime States.

(3) That, with a view to arriving, if possible, at a uniform system in the various maritime States, it should be submitted to international expert opinion to decide whether, in addition to the above requirements, a uniform system of fixing a special load line and for absolute regulations restricting height and weight of deck cargoes would be desirable.

(4) That, in any case, the British regulations with regard to light woods can be modified with advantage.

(5) That the Maritime Law Committee take such steps as may be required to induce the Governments of the various maritime countries to arrive at an international understanding on the lines above mentioned.

Government Investigation Threatened

CONSIDERABLE excitement has been created among marine underwriters of late by intimations from Washington that the Government is seriously considering engaging in cargo insurance on account of the alleged discrimination made by underwriters against Shipping Board boats. The Washington authorities insist that shippers making use of Board vessels are charged a substantially heavier rate than is asked for regular liners and that this increases the overhead to an extent that militates seriously against the upbuilding of our merchant marine. This has been specifically denied by the marine insurance men. They point out that insurance is a science and that in the making of rates due consideration is necessary for such elements as past records of steamship lines and the experience of those operating them.

It would be a gross injustice to operators of lines that have shown a favorable record through a long term of years to charge them an added rate in order to offset losses likely to arise at the hands of less capable operators. However, the latest authoritative information from Washington is to the effect that the Shipping Board commissioners have finally abandoned the idea of putting the Government into the business and now propose to limit their activity as regards marine insurance to a thorough investigation. "We propose," says Commissioner Meyer Lissner, "to make a thorough scientific investigation and not to jump to any hasty conclusions."

Doubtless the reason for not carrying out the original

threat has three angles. The Jones Act does not grant authority for the Government to go into the business; no appropriations committee would grant the large sums necessary; and the country is in no temper to support the idea of more Government in business. The Shipping Board has named a commission to study the marine insurance situation, and Commissioner Lissner is at its head. One of its first efforts, so it is stated, will be to obtain the co-operation of underwriters in naming rates equal to those on privately owned tonnage.

The Burning of the "Tanamo"

A NUMBER of interrogations were received by the underwriters after the sinking of the steamer *Tanamo* with its cargo in New York harbor. Those interested in risks of this character were anxious to learn how nearly their insurance policies covered them. It appears that a fire raged in the hold of the ship during a considerable part of the trip from Porto Rico to New York and the only way it could be controlled was to open the seacocks and permit the vessel to fill. The fire damage is, of course, a particular average; the damage done by the sinking will be made good in general average. Even though it is shown that the fire was of incendiary origin, as is suspected, the liability of the underwriters will not be reduced, as fire and its consequences are covered unless the fire be occasioned by an agency specially excluded from the policy; and this is not the case with ordinary incendiarism.

Encouragement From the Courts

TWO court decisions have recently been most favorably received by the marine underwriters. One was the fine of $250 imposed on the *Santa Tecla* by Judge Learned Hand of the United States District Court of New York for violating the regulations with regard to polluting the waters of the harbor by the discharge of waste oil. The offense was committed at Pier 33, South Brooklyn, nearly a year ago, and the circumstances were an attendant permitted a tank to overflow while the vessel was receiving her supply of fuel oil. The campaign against polluting harbor waters by oil discharge has been actively backed by marine insurance interests, and by fire men as well, largely because of the extreme danger to shipping and harbor property occasioned by floating oil. Federal legislation along this line is under consideration at this time by the Rivers and Harbors Committee of the House. It is believed that regulations will be devised for the control of this perilous practice and that in them will be included an arrangement for disposing of oil waste at our chief ports by means of adequate plants that will pay for the oil and carry it off to be burned after the valuable by-products have been extracted.

The second piece of court encouragement came from the Federal District Court at Norfolk, Va., which returned indictments charging the owner and three members of the crew of the *Charles G. Endicott* with conspiracy to scuttle the ship and also with actually casting away a vessel at sea. The *Endicott* was an American schooner. She sank last February off the Cuban coast while carrying a cargo of coal and her ten survivors told an identical tale of collision with a floating mine. She was insured in the New York and London markets for $181,000 on war risk coverage and $176,000 on straight marine. The actual value of the ship was figured at about $100,000, even at a time when values were very high; the remainder fell under the head of charter property insurance. Some of the insurance was paid, but the foreign underwriters instituted inquiries that have finally resulted in the action taken by the Federal court at Norfolk. In this connection it is interesting to recall that a statute still survives that makes the crime of barratry punishable with death; the offense charged against those held responsible for the sinking of the ship, however, is of a statutory nature other than barratry.

Builder's Risks on Equitable Basis

BEFORE the commencement of shipbuilding on such a large scale in the United States all builder's risks, whether of steel or wooden construction, were covered under a form known as the "Institute Clauses for Builder's Risk." The worst feature of this form was a clause which gave the builders permission to increase the value from time to time, and also provided that in the event of a loss the sum insured should be regarded as the insured value. When the American Hull Builder's Risk Committee took up the task of drawing up a new builder's risk form, one which would be equitable to both assured and assurer, they immediately changed this clause. The value of the vessel insured was to be at all times the completed contract price of the vessel, and the whole amount was to be insured from the date of laying of the keel.

The reason for this clause is: Where insurance is placed in installments the average liability under a policy is increased. The larger number of installments the more nearly the average liability approaches the full amount of the policy, making the real the same as the apparent rate; the real rate being the actual rate on the liability assumed, and the apparent rate being the rate at which the policy is written. Therefore one result of insuring on the installment plan, and indeed the underlying reason why assured and brokers always favor the installment plan, is to reduce the rate which had already been agreed upon as the proper one.

Valuing the property—that is, the vessel insured—at the amount of valid insurance in force at any given time is extremely objectionable, because a company never would know just what proportion of any loss it would be called upon to pay, or its ratio of liability.

Rating Shipping Board Vessels

MARINE insurers are wondering how the Shipping Board commissioners can reconcile the clamor for lower rates on their boats with the announcement of Chairman Lasker that of fourteen hundred steel vessels owned by the Board one-third are useless for ordinary commerce and another one-third are but moderately suitable. Coming on top of Commissioner Lissner's declaration that Shipping Board vessels are just as good as any other vessels and entitled to as low an insurance rate as the best, this would indicate a considerable divergency of opinion. It is reported that the A. G. W. I. Lines have turned back their lake-built boats to the Shipping Board on the ground that they could not be operated profitably. These boats were constructed for coastwise trade and, if steamship lines engaged in coastwise service can not operate such vessels profitably, they might, it would appear, as well be scrapped now as to be maintained in idleness for several years before the scrapping takes place. Underwriters are wondering whether Commissioner Lissner is of opinion that they should be operated transatlantic at approved liner insurance rates.

Gothenburg Dry Dock Built in Germany

In a description of the new dry dock at Gothenburg, published on page 445 of our June, 1921, issue, it was stated that this dry dock was built by the owners, the Eriksbergs Mek. Verkstads Aktiebolag, Gothenburg. Since the publication of this article we have been informed that the dock was built for the above company by the Brückenbau Flender Aktiengesellschaft, Benrath and Lübeck, Germany, from designs by Mr. von Klitzing of Hamburg.

U. S. S. Tampa, the First of the New Electrically Driven Coast Guard Cutters

Electric Drive Applied to Coast Guard Cutters

Cutter Tampa Driven by First Synchronous Motor Built for Marine Propulsion—Practical Advantages of Synchronous Motor

By Captain Q. B. Newman, U. S. C. G.*

IN discussing types of propelling machinery for ships, the points usually considered in the order of relative importance are reliability, efficiency, durability, weight, space occupied and cost to construct and install. For many years the machine which answered the requirements more fully than any other was the faithful old reciprocating steam engine with its multiple expansions.

The Revenue Cutter Service, forbear of the present Coast Guard, had an honorable part in its development and took a pardonable pride in its achievements. There is scarcely an American text book on marine engineering which fails to include somewhere the classic experiments on the *Rush, Gallatin, Dexter* and *Dallas* to determine the effects of steam jackets, the benefits of compounding and the merits of small bore and long stroke as compared to large bore and short stroke.

One day a ruthless scientific person pointed out that the multiple expansion engine is not sufficiently expansive and that, inasmuch as half of the original energy of the steam is still in it at atmospheric pressure, we should travel down the vacuum line till it begins to touch bottom, if we would have real efficiency. Someone else suggested that superheated steam would catch a lot of heat that formerly went up the stack, and the days of the reciprocating marine engine began to close. For, although the low pressure cylinder had been divided into two, it was still too restricted and superheat was bad for cylinder lubrication and for high pressure rods.

At the head of the list of Coast Guard requirements is responsiveness. You can back up on a lee shore till there is only a foot of water under the keel, if you are absolutely sure there is instantaneous power at the other end of the telegraph, but you cannot do it with confidence if you must wait half a minute or a minute while a turbine gathers way. And so the Coast Guard was forced to adhere to the reciprocating engine for a long time after it began to lose caste elsewhere, because it was the only machine which had this quality of responsiveness.

The *Jupiter* demonstrated beyond doubt the availability of electric machinery for marine propulsion, combining the high efficiency of the steam turbine with all the maneuvering promptness of the reciprocating engine. Later came the *New Mexico,* which confirmed previous experience and removed electric propulsion from the realm of conjecture. Both of these ships, however, used the induction motor, whose low power factor (about 78 percent) necessitates increased sizes of copper conductors and therefore of machinery throughout.

Propelling Machinery of New Cutters

The development of a propelling outfit suitable for small ships of relatively low power was taken up in the summer of 1919, when, in a series of conferences between engineers of the Coast Guard and the General Electric Company, the

plant described below was worked out and later installed in the Coast Guard Cutters *Tampa, Haida, Mojave* and *Modoc.*

The main turbo-generator is very similar in all essential characteristics to the machine which the General Electric Company has been building for a number of years for shore stations. The turbine has eight stages, runs at 3,000 revolutions per minute and delivers its power to the generator through a flange coupling. Steam conditions are 200 pounds pressure (gage), 75 degrees superheat and 2 inches back pressure.

Speed regulation is controlled by an oil governor. The speed lever on the operating panel opens a leak-off in the oil system, thereby lowering the pressure. The throttle valve gear is operated by a governor spring working against the oil pressure, so that lowering the oil pressure by means of the leak-off allows the spring to open the pilot valve on the main hydraulic cylinder which increases the opening of the throttle valve.

Auxiliary exhaust steam at 7 pounds (gage) pressure is admitted to the fifth stage of the main turbine. This accomplishes three purposes, all of major importance. It fixes proper conditions for heating the feed water, it utilizes the main turbine to wring all the heat from the auxiliary exhaust and it protects the vacuum against air leaks in the auxiliary exhaust piping.

The main generator is a two-pole, three-phase, 50-cycle machine, generating 2,040 kilowatts at 2,300 volts. One

forging is used for the revolving field, shaft and journal. Slots for the windings are milled in the body of the rotor. The field windings are of flat copper strips adequately blocked against motion in any direction and protected by heavy metal wedges and rings.

The propelling motor, however, is the novel part of the installation, for up to the time these ships were designed the synchronous motor had never been proposed for marine propulsion and the motor in the *Tampa* is the first one built for that purpose. Delays of one sort and another, in no way related to the engineering problems, robbed the *Tampa* of the distinction of being the first ship propelled by a synchronous motor, the S. S. *Cuba* having carried off that honor.

Synchronous vs. Induction Motor

The synchronous motor has a number of features which recommend it, rather than the induction motor, for a propelling machine, chief of which is electrical. Alternating current machinery in general has the characteristic that the current lags behind the voltage whenever the circuit is inductive, that is, the induction resists the rise and fall of current and chokes it back behind the voltage. The lag is expressed as an angle in magnetic degrees, just as a geometrical angle is expressed in degrees of arc. The cosine of the angle of lag is called the "power factor." For example, if the current in a circuit lags 37 degrees behind the voltage, the power factor would be the cosine of 37 degrees, or about

0.80. The effect of power factor is that, instead of taking the product of volts and amperes to get power, that product must be multiplied by the power factor.

In the example cited above the actual power would be only 80 percent of the product of volts and amperes. Heat losses in the main circuit of generator, motor, controls and cables vary with the square of the current, so it is extremely important to keep the current as small as possible, which for any given power requires that the power factor be high. Citing again the 80 percent factor and comparing it with a 100 percent power factor the sizes of all conductors in the main circuit would be in the ratio of about 1½ to 1 with a corresponding difference in size and weight of the whole machine. And, be it noted, 80 percent is a high power factor for an induction motor suitable for ship propulsion, whereas

U. S. Coast Guard Cutter Tampa—Lubricating Oil System

the power factor of a synchronous motor is 100 percent. The difference in weight and size is sufficient, in the case of these Coast Guard ships, to determine the possibility of electric drive, i. e., the synchronous motor could be used but the induction motor could not.

The next most important difference between the two types of motors is a mechanical difference with an electrical reason. In order to get as high a power factor as possible, the induction motor must have the smallest possible air gap between stationary and rotating parts, with the result that only limited wear can take place in the bearings before there would be trouble. The air gap of the synchronous motor is usually about 3/8 inch making such trouble extremely improbable. In addition there is a very real advantage in the accessibility of a synchronous motor for repairs. The direct current poles are radial pieces bolted on the outside of the rim of the rotor wheel. They are readily detachable and by removing a few of them any part of the stator windings can be removed or repaired without having to lift heavy weights.

Alleged objections to the synchronous motor, on the part of people who ought to know better, have been urged so persistently as to create honest doubts of its merits. A synchronous motor is alleged to have poor starting qualities when as a matter of fact it has none at all. Neither has a disengaged clutch. But nobody leaves a clutch disengaged, if he wants it to work; neither does he try to get starting torque in a pure synchronous motor. He puts on a simple, cheap and effective squirrel cage winding which brings the motor up to speed and then goes out of business. Such motors have been used successfully for years in rolling mills, probably the most rigorous conditions to be found anywhere, reversing under terrific load every few seconds year in and year out; yet the question is raised whether it will reverse a ship's propeller. Anyhow the question is answered; the *Tampa* has been brought dead in the water from 15 knots in her own length, which should be rapid enough to satisfy the most exacting.

The theory that the motor would fall out of step in a sea way has also been disproved.

The question of whether the addition of a direct current field constitutes an objectionable complication may be a matter of opinion. The theory of this field is simple and readily understood and, if there are more switches, etc., required, they are all mechanically rugged and easily kept in order. The complication is no greater than in an induction motor with external secondary resistances and not so great as in an induction motor with apparatus for improving the power factor.

The motors used in the Coast Guard have 46 poles, giving a speed reduction of 23 to 1. The power developed is 2600 shaft horsepower at 130 revolutions per minute.

Duplicate exciters are installed. Each is a turbine-driven, three wire, 240 volt generator, furnishing sufficient current for excitation and for all lighting and power purposes.

Engineers Extol Westinghouse

"The Life of George Westinghouse," by Col. Henry G. Prout, will soon be published by the American Society of Mechanical Engineers for the following committee: Charles A. Perry, chairman, Paul D. Cravath, Alexander C. Humphreys, James H. McGraw, H. G. Prout, Charles F. Scott, L. B. Stillwell, Ambrose Swasey, H. H. Westinghouse.

"To the memory of few other men, if any, do the engineers of America owe so great a debt of gratitude as to that of George Westinghouse, whose inventions and achievements have not only benefited mankind, but have made possible the enterprises in which so many of our number are now engaged," said Calvin W. Rice, secretary of the society, in a statement explaining that "the underlying motive for publishing a biographic series of great American engineers is to inspire others."

Railroad Contracts With Foreign Shipping Lines

(*Concluded from page* 12.)

would route business that was to be transferred to ocean-going ships, the vice-president declared that his road does not route business at all but merely advertises sailings and allows shippers to choose. And, he stated furthermore, that if there is a congestion of vessels at the docks, all are required to take their turn, regardless of whether of a contract line or not.

Berthing Facilities Denied American Vessels

Despite these assurances the Shipping Board commissioners were plainly dubious regarding the effect of contracts with foreign lines. The chairman said that he knew of actual cases where berthing facilities had been denied to American vessels because of the existence of such agreements. It availed nothing that a railroad company had a fine moral feeling for American shipping, if it was confronted with the physical inability to accommodate American ships because of foreign contracts. With a record of two and one-half million tons of cargo interchanged last year between the ten American railroads represented at the hearing and ships operating under the flags of nations other than the United States it was imperative that steps be taken to give effect to Section 28 of the Merchant Marine Act which clearly defines the intent of Congress that American railroads be preferential feeders of tonnage for American ships.

As an earnest of the harmlessness of existing contracts, the vice-president of the Baltimore & Ohio said that the agents of the Donaldson Lines and Furness Withy and Company had already recommended to their principals that their contracts be cancelled, such was their realization that under present conditions in the United States, such contracts could give to a foreign shipping interest no service or co-operation not available to all rivals. But for all that the Baltimore & Ohio contracts were, in his estimation, virtually inoperative, the vice-president hesitated, on his own initiative, arbitrarily to cancel contracts entered into in good faith with responsible people unless the contractors were willing. Other railroad executives who were present were much more ready to meet the wishes of the Shipping Board without debate or delay. For example, Vice-President L. Green, in charge of traffic of the Southern Railway and Mobile and Ohio Railroad, stated that from what he had heard at the conference he sensed the sentiment of the Shipping Board and that, unless the Board requested him not to do so, he would forthwith take steps to cancel the contracts held by his roads. The attitude of several of the railroad executives is that the contracts that the Shipping Board is objecting to have served their purpose and might as well be scrapped. Owing to the change of conditions, they hold that such contracts can no longer be preferential. Each road and each shipping company is now compelled to work for business wherever it can get it.

Senator France of Maryland has introduced in the Senate a bill, S. 2620, to provide a fundamental change in the method of determining wage scales for employees of government navy yards and arsenals. The bill provides for the creation of a board of adjustment which shall have final jurisdiction and authority to decide upon all questions relating to changes in wage scales and controversies or grievances concerning conditions of labor. The board would be composed of three members.

Edgar Palmer's Three Masted Auxiliary Schooner Yacht Guinevere

Auxiliary Schooner Yacht Guinevere

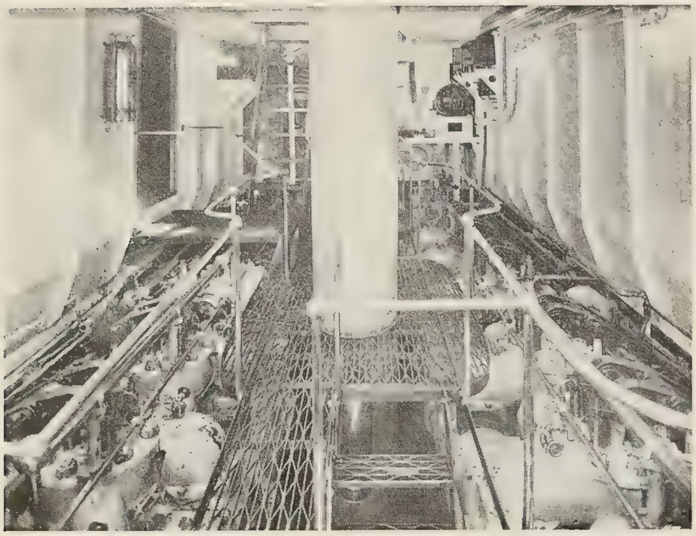
The Largest Fore-and-Aft Auxiliary Schooner Yacht Ever Built Equipped with Diesel Electric Drive

THE successful 14,000-mile cruise of the auxiliary schooner *Elfay,* which had the first Winton Diesel-electric drive ever installed in a vessel, influenced Edgar Palmer of New York to include a similar type of propelling unit in his new yacht *Guinevere* designed by A. Loring Swasey and Arthur Raymond of Boston. This yacht has the distinction of being not only the largest Diesel yacht built in this country but also the largest fore-and-aft auxiliary schooner yacht in the world.

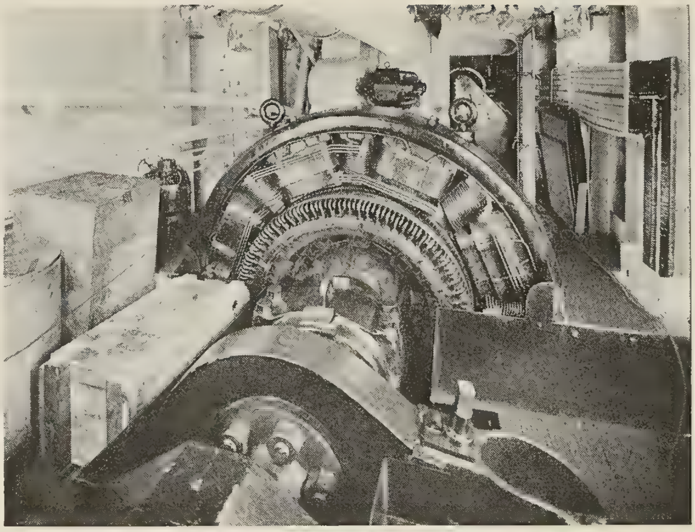
The *Guinevere* has an overall length of 195 feet, a length on the waterline of 150 feet, a molded beam of 32 feet 5 inches, a draft of 15 feet and a displacement of 642 tons.

Main Saloon

Owner's Bedroom



View of Engine Room from Upper Grating



550 Horsepower Propelling Motor

The power plant consists of two Winton Diesel engines which develop a total of 700 horsepower. Each engine is direct connected to a 225-kilowatt Westinghouse shunt wound generator. Current for propelling the yacht is supplied through the main switchboard to a 550-horsepower Westinghouse electric motor which gives the vessel a speed of 11½ knots without employing her sails. The electric propelling unit was worked out by the designers with suggestions from Commander Fisher of the United States Navy. The yacht has a fuel capacity of 95 tons of oil and stowage space for supplies sufficient for a cruising radius of 11,000 miles.

The Winton Engine Works and the Westinghouse Electric & Manufacturing Company constructed the power plant and driving generators and motors. The ship was built by the George Lawley & Son Corporation at their yards in Neponset, Mass.

Deck House and Cabin Arrangement

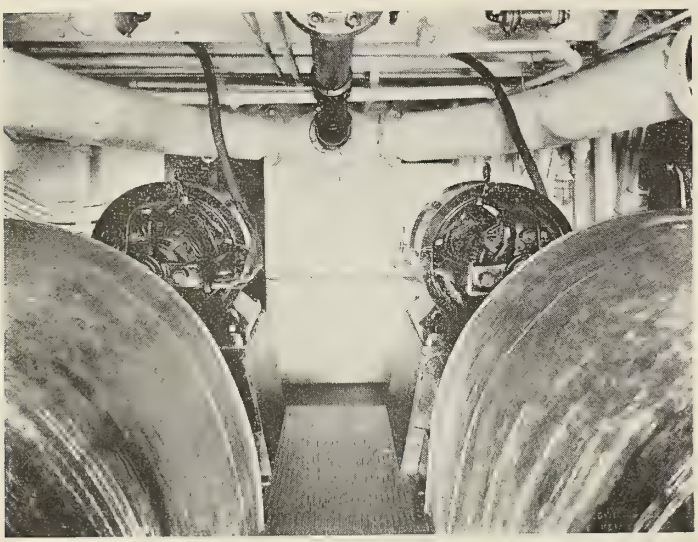
The comparatively small space occupied by machinery in the hull allows a roomy arrangement of cabins below decks and more spacious living accommodations, crew's quarters, capacity for stores and the like than is generally the case in auxiliary yachts, especially if they are steam driven. In addition to these advantages the stack is eliminated allowing space for an extra deck house. The exhaust is at the after end of the boat under water so that soot and gas fumes are carried well away from the yacht.

The main power plant consists of a pair of 6-cylinder 350-horsepower model 24-A Winton Diesel oil engines having a bore of 13 inches, a stroke of 18 inches and an operating speed of 225 revolutions per minute. Each engine is direct connected to a 225-kilowatt Westinghouse shunt wound generator, which in turn operates through a chain drive a 15-kilowatt, 125-volt direct current compound-wound Westinghouse exciter, turning at 1,150 revolutions per minute. This power unit supplies current to a 550-horsepower, 250-volt Westinghouse propelling motor operating at 220 revolutions per minute located in the stern.

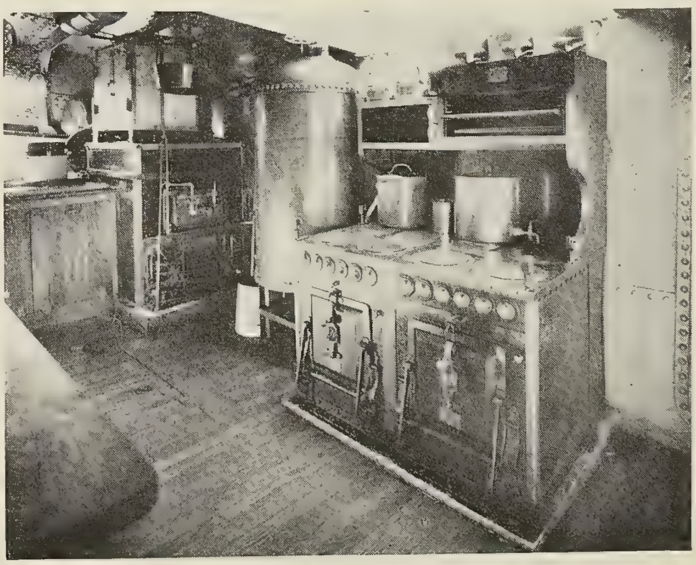
Propeller

The propeller, constructed according to the Bevis patents, is two-bladed, having a diameter of 8 feet 4 inches. The greatest advantage of the twin engine drive installed in the *Guinevere* is its maneuvering ability as well as the possibility of cruising at reduced speed on one engine or at full speed on both engines if it is desired. In the case of engine repairs a single engine and generator unit is able to carry the load while the other unit is shut down.

An interesting feature of the installation is that the generators are not only ring-oiled, as is the usual practice, but provision is also made for flooding them with oil from the lubricating systems of the Diesel engines. This provision is made so that they will operate satisfactorily whatever the list of the ship might happen to be.



Generators and Exciters



Galley, Showing Electric Range

The driving motor is enclosed at its forward end, but an inlet is provided at the top for the intake of cooling air. Centrifugal fans direct connected to a 1¾-horsepower motor furnish approximately 3,500 cubic feet of air per minute for ventilating the propelling motor.

METHOD OF OPERATION

The method of operation for this drive is practically the same as that used in the auxiliary schooner yacht *Elfay*. For cruising at full power the two main generators are connected in series furnishing current to the motor. The generators and motor are in this case arranged for separate excitation at 125 volts on the exciter circuit. The speed of the motor from zero to maximum in either direction is controlled by means of the reversing rheostat which controls the excitation of both generators and thus the generator voltage, which determines the speed of the motor. This arrangement makes it possible to operate the ship at almost any speed desired up to the maximum ahead or astern. It also allows for reversing without interrupting the main circuit.

Unlike the *Elfay* the *Guinevere* power plant is controlled from the engine room by signals from the pilot house. The reversing rheostats are mounted at the rear of the switchboard panel and are operated by a hand wheel suitably marked on the front of the panel board. In addition to the reversing rheostat this panel carries an automatic circuit breaker for overload production, motors, knife switches for the generator and motor field circuit, and a two-pole double-throw knife switch for each main generator armature circuit. By means of the latter switches each generator may be connected in series with the other generator or disconnected, leaving the other generator connected to the motor. This arrangement makes it possible to operate at reduced speed when one generator is shut down or when it is desired to operate the ship at low speed for a considerable length of time. Each of these switches has an extra auxiliary control panel in case that it becomes necessary to use more power than is supplied by the auxiliary generating units.

AUXILIARY EQUIPMENT

The auxiliary equipment aboard the *Guinevere* includes a two-ton Clothel ice machine and a pair of 15-kilowatt generators for auxiliary work, each of which is operated by a 25-horsepower Quayle engine. All other auxiliary equipment throughout the boat, such as bilge pumps, fire pumps, service pumps, ventilating fans, hoists, both anchor and sail, wireless equipment and the like are operated by electric power, no steam being used on the boat. The galley equipment, ovens, heaters, hot pans and the like are all heated by electricity. Electric radiators are used for heating the living quarters and cabins throughout the yacht.

GYRO STABILIZER INSTALLED ON GUINEVERE

To give greater steadiness at sea while sailing under power the *Guinevere* has been fitted with a Sperry gyro stabilizer of the active type. The rotor for the stabilizer is 78½ inches in diameter by 17¼-inch face and weighs about 22,000 pounds. It is designed to operate at 1,700 revolutions per minute. Because of the air friction against the revolving element, which increases almost as the third power of the peripheral velocity when the gyro is running at more than half speed, the casing in which the wheel is enclosed has been exhausted of air to a 15-inch vacuum thus reducing the windage losses and saving about 13-horsepower on the equipment. On the *Guinevere* power is supplied for the driving motors of the gyro from the main generators through the main switchboard. The stabilizer equipment is installed in a special compartment just forward of the engine room.

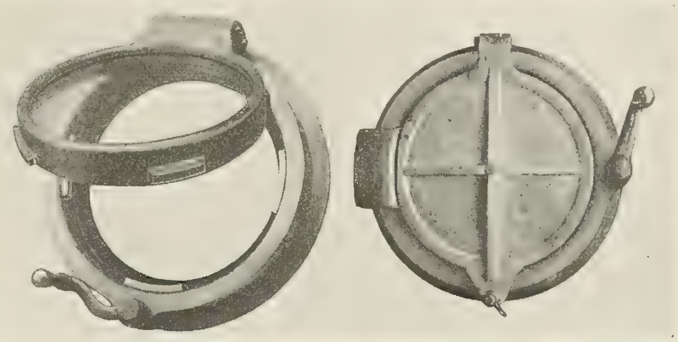
Following out the plan to have the yacht as completely controlled by electricity as possible, she is fitted with a Sperry gyro compass. A repeating compass, electrically operated by the master gyro, is located in the owner's quarters.

The *Guinevere* reently completed her sea trials and a full power run from Boston to New York on which the yacht's performance was satisfactory. She was then fitted out for an extended Atlantic cruise and is now on a run to Cuba.

Air Port Operates on Breech Block Principle

TO facilitate the opening and closing of air ports and to eliminate the glass breakage caused by uneven tightening of tumble bolts the Steward Davit and Equipment Corporation, New York, has produced a new type port which is controlled by the turning of a small handle.

The appearance of the glass frame of this port is similar to the conventional type except that in place of the dogs for tumble bolt nuts it has four fixed wedges on its outer circumference. Inside a fixed frame which is attached to the ship's plating is located a ring gear which has teeth on its outer edge for about a quarter of the circumference. These



Air Port Open Deadlight Closed

teeth are operated by a small pinion attached to a crank handle. On the outer edge of the ring gear opposite the gear teeth is a section made in the form of an interrupted spiral gear which engages with a second spiral gear attached to the cover hinge. The ring gear also has four wedges on its inner circumference which engage the wedges on the glass frame.

To open the port the crank handle is turned and this revolves the ring gear until the wedges clear those on the glass frame. Continuing to turn the handle causes the ring gear spiral to engage with the spiral on the hinge and opens the light. The handle, wedges and spiral gears are timed in such a way that the handle clears the opening light, the wedges clear and then the spirals engage—all in one continuous motion. The light is thus opened and held in position at any angle without any further operation.

To close and tighten the port the motion is reversed; the whole movement being similar to the operation of the breech block on a heavy gun.

British Lines Cut Rates

VICE-PRESIDENT LOVE of the Emergency Fleet Corporation said on December 7 that reports from London that British steamship lines were planning a rate war against United States vessels were based on a rate war between British lines. According to official reports to the board, the action of the British lines was taken without regard to competition by American vessels.

Mr. Love said it appeared that the Ellerman Line, a British company, had announced it would enter the European-Pacific coast trade and that then three other British lines already in that service—the Furness, Harrison and Holt companies—met that announcement with cutting their rates in half.

American Shipbuilding Returns for 1921

Output of Merchant Tonnage Three Times Pre-War Record—Much Repair Work in Sight—Important Developments Looked for in 1922

WHILE the year 1921 will go down in the annals of shipbuilding as one of the lean years when contracts for new construction were few and far between, this does not mean that our shipyards have been idle for the past year. On the contrary, they have produced a total of 1,140,785 gross tons of shipping, which is approximately three times the best record of the years 1900 to 1915 inclusive and which approaches very closely the output for 1916 when the boom due to the war began. Practically all of this tonnage, however, was contracted for in the latter part of 1920.

The falling off of new business in 1921 was not confined to shipbuilding alone but extended to all lines of industry due to the exceptionally unsettled state of the world's markets and the declining volume of foreign commerce.

Conditions were further aggravated by the large number of Government owned vessels laid up and the failure of the Government to adopt a definite policy with regard to our merchant marine.

That officials in Washington at the present time are fully alive to the needs of the world is demonstrated by the initiative shown in promoting the Limited Armament Conference, with a view to lightening the military burden of all nations to the benefit of commerce, and by seriously taking up the question of ship subsidies as a means of placing our merchant marine in a position to meet foreign competition in world trade.

Armament Conference

The limited armament conference now under way in Washington, while at first viewed with alarm by the shipbuilders of the United States, is assuming an aspect which may prove a distinct boom to the merchant marine.

Definite peace arrangements consummated as a result of this International Conference will go a long ways toward stabilizing business all over the world with a resulting increase in foreign trade that will quickly reduce the idle tonnage now gracing so many of our ports. This may be better realized from the fact that, based upon the pre-war rate of increase, there is a deficiency in world tonnage at the present time amounting to some two and a quarter million tons. As trade returns to normal it is evident that this tonnage will have to be made up and this figure will be further augmented on account of a large number of the older vessels being scrapped.

Subsidy

The question of some sort of a subsidy for the American merchant marine to offset the difference in standards of personnel, which exists between the United States and foreign countries, seems very likely to be settled by the early part of 1922.

A special committee of shipowners, operators and builders has been working on a plan for subsidies for several weeks past and President Harding has requested this committee to have its report in his hands by January 1. The President, it was learned, plans to take up the question of ship subsidies in a special message to Congress the first week in January.

The question of a subsidy will open the whole subject of our merchant marine and undoubtedly result in the adoption of definite policies which will stimulate interest and lead to important developments in our water borne transportation systems.

That subsidies were responsible for the success of early American transatlantic lines and also for the present position of pre-eminence of the British steamship lines is shown by Winthrop L. Marvin on page 5 of this issue.

Tonnage Now Under Construction

According to the latest figures available, there are at the present time 322,680 gross tons of steel merchant vessels under construction in the United States. This tonnage, while seemingly low when compared with the record years of the war, exceeds the annual output of any year between 1900 and 1915 with the exception of 1906 when 348,555 and 1907 when 450,017 gross tons of shipping were produced.

Passenger Ships

It has been stated that the United States needs at least one hundred fast passenger vessels to balance its huge fleet of merchant ships.

The present plans of the Government will increase the importance of this class of vessels and, with the adoption of limited armaments and the granting of a subsidy, there is no doubt that a number of vessels of this type will be included in the merchant construction work for 1922.

Repair Work

The large number of idle ships now in our ports is an assurance of busy times ahead for the ship repair yards. Every one of these vessels must be overhauled and reconditioned before again being placed in service. Many will be fitted with new machinery.

The motorship has made an enviable record for economical operation in the months of keen competition just passed and this type of propulsive power will undoubtedly be installed in a number of these vessels.

Conversion of Battle Cruisers

The conversion of the six battle cruisers, now under construction for the Navy, into fast passenger vessels is also gaining favor. These vessels would be scrapped under the armament limitation plan and their conversion would provide a nucleus for a future fleet of passenger ships in addition to offsetting the monetary loss involved. It is estimated that these vessels can be fitted to provide accommodations for from 3,200 to 3,500 passengers in addition to providing for the carriage of at least 2,500 tons of freight. These vessels would provide a nucleus for a future fleet of passenger ships and would undoubtedly be well patronized as affording the greatest amount of safety afloat due to the unusual watertight subdivision of the hull.

Ship Breaking-Up Industry

Another possible development of the Limited Armament Conference will be the establishment in this country of a number of firms for the purpose of breaking up and salvaging material from vessels discarded by the Navy.

This will be a new business undertaking in the United States, and judging from some of the results obtained in Europe is likely to prove a profitable undertaking.

While there has been an expression of pessimism regarding the shipbuilding situation in many quarters, the returns for the year just ended show a gratifying figure for tonnage constructed and the new developments now taking place indicate a normal business for 1922.

Shipping and Shipbuilding in Great Britain in 1921

By W. H. Wendon

The year which has just closed has been one of keenest anxiety to those engaged in all branches of shipping—whether builders, engineers, repairers, owners or brokers. Following the artificial boom conditions during the period of the war and immediately after, the weak points in the armor of the newly-established companies were clearly shown up, with the result that failures have been frequent. More than that, many companies whose affairs have not already been placed in the hands of a receiver are shivering on the brink of attaining that unenviable distinction.

IT is noteworthy to reflect that the opening of the year 1921 practically synchronized with the dawn of disillusionment in the minds of the majority of those dependent on industry. It was not unnatural, therefore, that, so far as shipowning was concerned, schemes should be mooted having as their object the improving of the freight situation. The most concrete plan, and that which aroused the greatest interest, was propounded in March by Sir Owen Philipps, the newly elected president of the Chamber of Shipping of the United Kingdom.

Schemes for Improving Freight Situation

Pointing to the fact that at that time there was an excess of no less than ten million tons of merchant shipping as compared with 1914, Sir Owen Philipps urged in no uncertain manner the scrapping of the unusually large number of old vessels of all countries, which craft, owing to their age, construction or design, must be unsuitable to compete in the strenuous times that lie ahead. Sir Owen Philipps further contended that the sooner these obsolete vessels were broken up, the better for all concerned and, in the interests of both shipowners and shipbuilders and their employees, he expressed the hope that the industry of the shipbreaker, which had fallen into abeyance since 1914, would again become active, as otherwise he feared that shipbuilders in Great Britain and abroad would witness a dearth of new orders for some time to come.

Shipbreaking Industry Revived

As all the world knows, this opinion has unfortunately been borne out by events. The keenness of Sir Owen Philipps' view that the older vessels should be sent to the shipbreakers is emphasized by his recent declaration that, in addition to the older vessels, the inferior new ones, built more or less for emergency purposes during the war, ought, in his opinion, to be broken up. The materials of which these vessels consist could, it is true, be made use of in some way or other, but against the adoption of this course there is at present one very real difficulty and that is that the cost of labor for breaking up a vessel often nearly equals the value of the material. But time, the great healer, will probably put matters right in this respect.

Voluntary Laying Up of Steamships

Another great factor in the attempt to adjust the unsatisfactory tonnage position has been the endeavor to formulate some workable scheme having as its object the voluntary laying up of steamships. Notwithstanding the fact that a very large proportion of the tonnage of the world continues compulsorily idle, there is still a great excess over the world's needs. It will be recalled that shortly prior to the war the freight market was flooded with tonnage and a scheme for a reduction in the number of the vessels in commission was formulated and ready for operation. But with the outbreak of war and the universal demand for steamship space, coupled with the enormous losses during the submarine campaign, every ship found its billet and the laying up plan was shelved. The subject came into prominence again in May last at the meeting in London of the Baltic and White Sea Conference. Sir William Noble, the president of the Conference, reminded the delegates that as far back as 1905, during a similar post-war depression, a minimum scale of freights was created. While this scale did not achieve all that was expected, it did arrest the fall and enable steamers to be employed. I mention this as a matter of historical interest, but I would add that, while from time to time during the past year the idea of laying up such a quantity of tonnage as would impel an increase in freight rates has been mooted, shipowners still seem as far off as ever of coming to some practical result.

The throwing on to the market of an immense amount of ex-German steamship tonnage has necessarily created dissatisfaction both among shipowners and shipbuilders. The very fact that about 400 of the ex-enemy vessels allocated to Great Britain have been disposed of should give a vivid indication of the chaos which occurred in the British shipping sale market. During the first nine months of the year shipbrokers were at their wits' ends as to the best means of conducting their business, but towards the close of 1921 "a certain liveliness" was discernible, one firm of brokers carrying through the then amazingly large number of 21 transactions during a period of three weeks.

Which brings me to shipping values. The transactions which have been recorded during the past year have been, to say the least, phenomenal.

Shipping Values

The most sensational deal was undoubtedly that connected with the fleet of the ill-fated Western Counties Company. The history of this concern is, indeed, a remarkable one. Prior to the late boom the company was the modest possessor of a few cargo steamers, but in December, 1919, it acquired the famous Moor Line fleet of thirteen cargo carriers, aggregating 82,000 tons deadweight. Notwithstanding that these boats averaged 11½ years of age, the expenditure of no less than £1,804,000 was required, equivalent to £22 per ton on the vessels' deadweight carrying capacity. In order to provide the funds for this huge purchase, the company increased its share capital from £274,000 to £1,250,000, the balance of the purchase price being secured by the issue of debentures. Within three months of the purchase of the Moor Line boats the Western Counties became the owners of the Sutherland fleet of 11 cargo steamers with an aggregate carrying capacity of 75,000 tons. For these vessels the expenditure of £1,825,000 was necessary. In order to carry through this acquisition, a further £1,000,000 was needed, and, as before, the public responded nobly, the issue being largely oversubscribed. With the crash in freight rates the company failed and in August eight of the boats were sold by order of the mortgagee for £266,150, as against £1,450,000 paid for them in February, 1920.

The Maindy Shipping Company, a Cardiff enterprise similar to the Western Counties, also met with a disastrous result, its fleet of ten steamers being seized by the mortgagees

in consequence of the company being unable to meet its commitments.

Shrinkage of Ship Values

As being representative of other remarkable shipping sale transactions which have taken place during the past year, mention should be made of the following: The *Michael Bistis,* of 5,850 tons deadweight, built in 1890, changed hands in 1919 for £160,000. In June last the most that could be obtained for her was £4,500. The Commonwealth Government's *Vermont,* of 6,800 tons deadweight, built in 1900, realized £110,000 when disposed of in 1916, and no less than £170,000 in May, 1919. During the past year she was again sold, but on this occasion only £15,000 changed hands. Two of the steamers owned by T. G. Beatley & Son (another firm whose financial affairs have been before the Bankruptcy Court) have provided instances of great depreciation in values. Their *Madame Midas,* of 3,624 tons deadweight, built in 1904, realized £16,750 when sold in December, 1909; £23,000 in November, 1912, and £63,750 in September, 1918. In November last, however, she was put up by auction in London and fetched only £11,350. The *Madame Brooke,* which was disposed of in March, 1917, for £37,500, realized only £9,000 in November last. These instances of depreciation could be multiplied many times, but suffice it that they are indicative of the melancholy state of the shipping sale market during the past twelve months.

Earnings of Steamship Companies

The earnings of steam shipping companies during 1921 have been on a much lower scale than of late years and, especially in the case of Cardiff companies, dividends have been noticeably attenuated. The position may be gaged from the fact that such efficiently managed companies as the P. and O. and Royal Mail Steam Packet have limited their distributions. The P. and O. was, perhaps, the bigger shock of the two, as it has always been the avowed practice not to distribute more to the deferred shareholders in any one year than can be maintained in future years. In the existing depression, however, the action of the managers is quite understandable and the course they have adopted is, after all, a wise one in reducing the distribution rather than paying more than the company can really afford.

The prices of shipping shares have not unnaturally been affected during the slump and in this connection the following table showing the values of the shares of representative companies in March, 1920, twelve months later and in December last, should not be without interest:

	Nominal value of shares	March, 1920	March, 1921	December, 1921
African S. S. Co.	£20	£33	£21	£23
Argentine Nav. Co.	1	1⅛	½	¼
Cairn Line	1	1¾	15-16	13-16
Clan Line	10	31½	9	8½
Cunard Line	1	2 3-16	15-16	⅞
Furness Withy	1	2⅝	1⅛	1⅛
Houlder Line	5	17	9	9
Indo-China	5	53½	35	33¼
Khedivial Mail	1	5½	5½	5½
King Line	1	2	1⅛	1
Orient Line	5	20	7½	9
P. and O. Co.	100	560	320	282
Royal Mail S. P. Co.	100	195	90	78
Anglo-European Co.	1/—	7/6	9d.	1½d.
Australasian United Co.	£50	£30	£40½	£40½
Britain S. S. Co.	10	46⅛	20½	20⅜
Canada Steamship	100	80	35	21
Court Line	20/—	44/—	28/1½	25/4½
Cressington Co.	20/—	42/—	26/—	27/1½
London-Am. Maritime Co.	20/—	36/3	16/—	16/—
Western Counties Co.	20/—	22/—	5/—	½d.

Theft and pilferage have been the subject of keen discussion throughout the whole of 1921 and great steps forward have been made in eradicating this world-wide evil. The policy of imposing a fine on the offender has been proved repeatedly to be of no deterrent value. The infliction of a sentence of imprisonment is the only effective manner of dealing with the miscreants.

Ministry of Shipping Abolished

The Ministry of Shipping came to an end during the past year. During its lifetime it was responsible for ordering 821 vessels in the United Kingdom and abroad; 279 of these were transferred to private owners for completion, the orders for 126 were cancelled, involving an expenditure by way of compensation of £500,000, and the remaining 416 boats were completed. Twenty-three of the latter were sunk, 15 were transferred to the Admiralty service as oilers and the balance of 378 were sold to private owners.

The total cost of the 228 ships built in this country was £36,481,000 and the selling price £47,591,000, showing a profit of £11,110,000; 122 ships built abroad cost £26,884,000 and were sold for £18,289,000, or a loss of £8,595,000, the net profit on the 378 ships being £2,515,000. If, however, 5 percent depreciation had been allowed, the net profit would have been increased from £2,515,000 to £5,122,000, while if a similar number of ships had had to be ordered from neutrals, it would have entailed an additional expenditure of £27,000,000.

There were larger receipts from the liner requisition scheme to the extent of £11,000,000, additional earnings of ex-enemy ships amounted to £9,600,000, and a further £579,000 was received from miscellaneous receipts, sales, etc. Recoveries from Allies, Dominions and trading developments totaled £13,250,000, sales of ships £1,680,000, and sales of shipyards and materials £70,000.

It will be gathered from the foregoing that the Shipping Controller's Department resulted in a substantial profit to the State.

Orders for New Ships Lacking in 1921

One of the most melancholy features of the shipbuilding and engineering trades in the past year has been the almost complete absence of new orders. Most of the yards have been pretty well occupied, but this activity is only traceable to the working off of the orders contracted many months ago.

The strike of shipyard joiners was particularly disastrous. The cessation of work commenced as far back as August, 1920, when the whole of the shipwrights employed in repairing on the Mersey struck work, without the authority of the executive of their trade union, to enforce the demand for a minimum wage of £6 a week. They eventually returned to work without gaining their object but, in the meantime, the loss of 400,000 working hours had taken place and the direct result of the men's action was to divert many important contracts to foreign countries. On December 1, 1920, the men again struck and then for many months the ship joinery industry of the country was in a state of chaos. Messrs. Cammell, Laird & Company, to mention one firm only, lost something like 700,000 working hours in consequence of this long drawn out dispute.

Watertube Boilers for Merchant Vessels

The suitability of watertube boilers for all classes of merchant vessels was given a good deal of prominence during the past year by the leading technical authorities. Sir James Kemnal raised the matter by reading a widely discussed paper before the North East Coast Institution and the subject was taken up by Mr. Waldie Cairns, who intimated that if ships sailed in good boiler water he might fit nothing but watertube boilers. For ships with high power of a large number of boilers—even sailing salt seas—he would consider watertube boilers favorably; but for moderate powered ships with, say, up to the equivalent of four large cylindrical boilers, he would like to know a good deal more about actual

performances before recommending steam generators of the type.

He adopted this standpoint mainly on the question of the weight of water in the system. In a ship of moderate power the weight of water had two rather important functions. A good weight of boiler water acted, for instance, as a "thermal fly-wheel," levelling up some of the inequalities in firing and fire-cleaning, which were very appreciable in moderate powered ships. The other function of a good weight of water was the capacity to take up, without rapid development of trouble, such quantities of sea water as might leak into the system from failure of a condenser tube or a condenser tube packing, which, even if detected, could not always be remedied quickly.

Taken all in all, Mr. Waldie Cairns is of opinion that there is good reason for caution. Moreover, bearing in mind the extra 100 tons deadweight capacity which Sir James Kemnal had indicated for a boat of 2,000 horsepower, this, Mr. Waldie Cairns believes, is not a great matter compared with the elasticity, handiness and general reliability of the old cylindrical boiler.

New System of Construction for Oil Tankers

Another technical feature of the past twelve months has been the adoption of a new system of construction in relation to oil tankers. The difficulty with which shipbuilders are confronted in building this type of vessel is to make a good connection of the centerline and the thwartship bulkheads, the present arrangement being expensive and altogether unsatisfactory. The new system referred to is claimed to achieve a perfect joint at a lower cost. It consists of a vertical plate lapped on the center keelson and extending to the oil deck with two tee bars, one on either side. The tee bars extend from keel bar to oil deck and form a "cross section" to which the horizontal plating of the centerline and transverse bulkheads is connected. This "cross section" forms a metal-to-metal joint, dispensing with the injection of cement or other substances.

It is claimed that by its use (1) all difficult riveting is eliminated; (2) three-ply riveting is reduced by 50 percent; (3) calking is reduced by 50 percent; and (4) the cost of erecting is reduced. The structure is so light that it can be erected with ordinary facilities. The bulkhead stiffeners and knee connections can be hydraulically riveted to the bulkhead plating on the ground before erection, leaving only the seams of the bulkhead plating to be riveted in position.

Another advantage is that the narrow plate, fore and aft, connected to the longitudinal bulkhead plating by a double-riveted lap increases the strength of the centerline bulkhead—which is, of course, of very great importance in oil carrying vessels in order that they may withstand the hogging and sagging stresses to which they are subjected.

Harland and Wolff's Increased Facilities

A mild sensation was created towards the close of the year when it became known that the great shipbuilding and engineering firm of Harland and Wolff, which already possessed yards at Belfast, Glasgow, etc., had undertaken a great repairing contract at the Port of London. It is noteworthy to recall that many years ago the shipbuilding and repairing yards of the Thames were one of its "glories," but one by one the companies were weeded out until only the smaller firms remained. However, Messrs. Harland and Wolff now have in their possession the right to do all the repairing and maintenance work required by the Port of London Authority and are under obligation to spend at least £300,000 in bringing the plant up to date. Despite the depression existing in all branches of the industry, Messrs. Harland and Wolff are making progress with their latest acquisition.

In regard to new vessels, on which subject many columns of this journal might be occupied, particular interest, perhaps, attaches to the twin screw Anchor Liner *Cameronia*, the first large liner to be laid down and afloat after the armistice, inasmuch as her launch in the remarkably short period of 9½ months from the laying of the keel constituted a record in British shipbuilding.

New Ships

The *Cameronia* represents a new type of intermediate Atlantic liner, embodying all the features hitherto exclusively found in "ocean greyhounds" and propelled by machinery of the most recent type, calculated to give the maximum economy of operating cost under all service conditions. The propelling machinery, supplied by Messrs. Beardmore, also the constructors of the hull, consists of two sets of Brown-Curtis turbines, each comprising one high pressure, one intermediate pressure and one low pressure turbine, astern turbines being incorporated in each intermediate and low pressure casing. The machinery develops at full power 13,500 shaft horsepower, sufficient to maintain a speed of 17 knots in moderate weather.

Both from shipowning and shipbuilding points of view, the formation of a company called the "British Trade Ship, Limited," with an unusually influential board of directors, was an outstanding event of the year. The object of the promoters of this scheme was to construct an exhibition ship *par excellence* and, if the indications are trustworthy, those responsible for the vessel will achieve at least this part of their program. The boat is now building by Messrs. Swan, Hunter and Wigham Richardson, Ltd., who are largely interested in the scheme. The intention is to send the vessel to the chief ports of the world in 1923 as a method of attracting business of all descriptions to commercial centers in the British Empire. The boat is to have a gross tonnage of 20,000 and a length of 550 feet, her extreme breadth will be 74 feet 9½ inches and her depth, molded, 44 feet 6 inches to the shelter deck. Her cruising speed in exhibition trim will be in the neighborhood of 12½ knots.

International Shipping Conference

In view of the complex problems which have confronted shipowners during 1921, it was not unfitting that a great International Conference, in which American delegates took a prominent part, should be held in London towards the end of the year. The leading questions of the day were discussed at length, and some momentous decisions were arrived at. The matters dealt with included the much discussed Hague Rules, the load line regulations, the carriage of wood cargoes on deck and the safety of life at sea. In regard to the last-mentioned, general satisfaction is expressed in responsible shipping circles in Great Britain that at last a serious attempt is apparently to be made to revise the Maritime Convention of 1914, a measure which has been postponed regularly at intervals of six months, and at the moment is under postponement until July 1, 1922. In the light of the experience gained during the war, it is not too much to hope that practical results will be forthcoming in the near future.

Another matter of world wide interest which has come into special prominence in the past year has been in regard to the dangers arising from floating oil in harbors and docks. After serious consideration of all the difficulties attending this important question, a representative meeting of shipowners agreed that it was essential in all cases that the provision, either directly or by contract, of barges or other convenient receptacles by the port authorities should be compulsory. For a long time there was disagreement on this point between shipowners and the dock and harbor authorities, but eventually the latter agreed that, although they could not submit to a statutory obligation to provide suitable receptacles, they would in fact do so at all ports where such receptacles were necessary. The shipowners accepted this compromise and it is more than probable that much good in regard to the modification of the floating oil evil will result.

Motor Passenger Liner Aba in Belfast Harbor

The First Motor Passenger Liner

The Aba of 8,000 Gross Tons and 6,400 Indicated Horsepower Assigned to Liverpool-Africa Route

By A. P. Chalkley

THE motor cargo ship has now become so common that new vessels fitted with oil engines attract comparatively little attention. Passenger liners, however, come within a different category and it is natural that the first vessel of such a class should arouse unusual interest among the shipping community.

To the well-known shipowners, Elder Dempster and Company, Liverpool, belongs the honor of placing the first motor passenger liner into regular service, the new vessel, the *Aba*, having sailed from Liverpool to Africa on her maiden voyage on November 16, 1921. This is a development of the greatest importance, for although she is not of the dimensions and speed of the large, modern transatlantic liner, the *Aba* is a comparatively large vessel as the following details will indicate.

Length, between perpendiculars	450.5	feet
Breadth	55.8	feet
Depth	36.6	feet
Gross tonnage, about	8,000	
Indicated horsepower	6,400	
Speed, knots	14	
Passenger accommodation (first class)	220	
" " (second class)	105	
" " (third class)	35	

The *Aba* was built in 1918 by Barclay Curle and Company on the Clyde as a cargo vessel, being then the *Glenapp*, and was in service for some months before her new owners, the British and African Steam Navigation Company (for whom Elder Dempster and Company are managers) placed her in Harland and Wolff's hands for conversion to a thoroughly up-to-date liner suitable for the regular passenger trade, the cargo capacity being cut down to 1,000 tons. She would have been completed many months ago had it not been for the prolonged delay to all vessels of this type caused by the joiners' strike at all British shipyards.

The Machinery

Before dealing with the passenger accommodation, which is equal to that of any transatlantic liner and contains many interesting novelties, a description may be given of the propelling and auxiliary machinery. The total power of the two main engines is 6,400 indicated horsepower, which is greater than that of any motorship afloat except for two motor cargo boats, the *Glenogle* and the new *Glenapp* owned by the Glen Line, in which engines of the same designed output are fitted. The motors in the *Glenapp* are of the Burmeister and Wain type and were built by Harland and Wolff of Glasgow. They each have eight cylinders, 29½ inches in diameter with a stroke of 43 5/16 inches, full power being produced at 120 revolutions per minute.

Burmeister and Wain engines are so well known that a few brief details of the design will suffice. It may be added that in general principle of construction, apart from the higher power and increased number of cylinders, they resemble fairly closely the machinery of the *William Penn*. They are of the four cycle type with the usual inlet, exhaust and fuel and starting valves, located in the cylinder covers, operated by long push rods which derive their motion from a camshaft, arranged about half way between the engine room floor and the top of the cylinders. On the camshaft are two side-by-side cams for ahead and astern running respectively. The reversing mechanism con-

trolled by a lever at the starting platform is so designed that when it is put into motion, by the reversing lever, it causes the push rods to be lifted off the cams, the camshaft to be moved, so that the astern cams come below the levers, and finally the push rods again to be brought into contact with the cams.

Starting Mechanism

Unlike most Diesel motors, the engines are each provided with two three-stage air compressors, supplying blast injection air at about 1,000 pounds per square inch while the starting air pressure is 360 pounds per square inch. Most of the other main engine auxiliaries are, however, separately driven by electric motors, except the eight small fuel pumps. After the reversing lever has been operated so that the valve gear is in the correct position for ahead or astern running as the case may be, the engine is started up by the movement of a single starting lever which admits air to the cylinders through the starting valves. The same lever also turns the cylinders over to fuel and speeds up the engine, thus giving a very simple control.

New Features of Design

There are one or two points in the design of the motors, which, so far as the writer is aware, have not been adopted previously on Burmeister and Wain engines.

Some of the cylinder covers have been made in two sections, the lower portion alone being subjected to a very high temperature. This section is spigotted into the upper part containing the valves. The object is that, should a crack develop, it will arise in this lower portion which can thus be more readily and cheaply renewed than if a whole cylinder cover had to be replaced.

A second important innovation lies in the construction of the pistons. Between the outer part of the piston, in contact with the liner, and the inner part, which is water cooled, there is an annular space around which air is allowed to circulate. The effect is a combination of water and air cooling which it is understood provides a better design than the usual system which is wholly water cooled. As is common practice with Burmeister and Wain engines piston cooling is effected by fresh water, a supply tank being arranged below the engine room floor. This piston cooling water circulates around a sea water cooler of moderate dimensions, but the cylinder jackets are supplied by sea water.

The spares carried for the main engine comprise two covers, two pistons, various valves and a number of minor accessories.

Electrical Auxiliary Machinery

As might be anticipated in a modern motor passenger liner, steam driven auxiliaries in the engine room and on deck are notable by their absence. A very small donkey boiler of the Cochran vertical type indeed comprises the whole steam installation, the object of this being for the provision of steam to the thermo tanks on deck by means of which hot air is supplied to the cabins and the dining saloon when the ship is in a cold climate. The only steam driven auxiliary is a small air compressor fitted only for emergency.

The electrical installation is very complete, as may be gathered from the fact that four electricians are carried. On deck are ten electric winches, an electric windlass, half a dozen electric exhausting fans and an equal number of variable speed electric motors driving fans in connection with the thermo tanks for the supply of warm air or fresh air to the cabins as required, this is delivered to a series of ducts, arranged with louvres in all of the cabins as well as the dining saloon. Electricity is used throughout the galley for cooking, while the bakery and the laundry are also supplied with electrically operated machines, even such details as the knife cleaning and boat cleaning machines being coupled to electric motors.

Apart from the thermo tank system of heating previously referred to, the main saloons are supplied by a new form of electric vapor heater which is used in connection with the electric plugs, in a similar manner to the normal electric radiator. The method of operation is, however, different, for the electricity is utilized for raising steam in a self-contained steam radiator. This is a new system which is now adopted for the first time and which it is believed is specially applicable to motorships where electricity is employed to such a large extent.

In the engine room a very large number of electric motors is required. The main auxiliary compressor, of which only one is installed instead of the usual two, is a three stage air high pressure machine driven by an 80 horsepower motor. The piston cooling pump is of the reciprocating type driven by a motor of 10 horsepower while for lubricating there are three electrically operated gear pumps. Salt water circulation for the cylinder jackets is effected by two electric rotary pumps, while the bilge pump, general service pump, fuel pump, turning gear and the DeLaval oil separator are all driven electrically. A large refrigerating plant has been installed of the CO_2 type and this comprises duplicate compressors and brine pumps.

Generally speaking when the ship is at sea, it is estimated that 300 kilowatts will be required and sometimes more. The electric generating plant is therefore on a large scale and there are three sets installed each with an output of 300 kilowatts driven by a four cylinder Harland and Wolff Diesel engine of 320 brake horsepower running at 210 revolutions per minute. The power is delivered to a very large switchboard at 220 volts and this pressure is used throughout the ship, not only for power but for lighting purposes.

Fuel Consumption

The fuel consumption of the ship is estimated at 20 tons per day which compares very favorably with 90 tons of coal required on a corresponding coal fired steamer and some 50 or 60 tons of oil which would be needed on a vessel equipped with oil fired boilers. The fuel tanks between the shaft tunnels have a capacity of 750 tons—sufficient for a voyage of 37 days' duration at full speed—and as on the round trip the vessel will be under way only for about 30 days there is ample bunker capacity for the whole voyage from Liverpool to West Africa and back.

Passenger Accommodation

The aim of the builders and owners has been to provide passenger accommodations equalling in luxury and comfort that which is obtained on the finest liners crossing the Atlantic.

The first class dining saloon which seats 220 passengers at small tables is arranged on the main deck right forward and occupies the whole width of the vessel, its height in the center reaching to the shelter deck. It is finished in white with gilt decorations and wedgewood placques somewhat in the Adams style, the furniture being of oak. On the same deck is the galley, bakery and all cabins required in connection with the supply of food while at the after end is the second class dining saloon seating about 100 people.

The other first class public rooms are all on the bridge deck comprising a first class lounge forward, a reading and writing room, and a smoking room right aft. The lounge is panelled in sycamore with carving and is fitted with wicker chairs with tapestry cushions while a piano is provided. The reading and writing room is painted grey and has a number of mahogany writing tables, the chairs and small tables being of wicker, while tapestry cushions are used throughout. The smoking room is of oak and like the lounge has an attractive electric fire with a tapestry panel above. Aft of this smoking room is an open air veranda and on the same (bridge) deck are two special suite cabins

Profile and Deck Plans of Motor Passenger Liner Aba

comprising a very large sleeping cabin and a sitting room, one furnished in oak and the other in mahogany.

The first class staterooms are all arranged amidships and are divided among the upper and shelter decks, arrangements being made for each to have its own port hole, this applying also to the second class cabins. Most are of the two berthed type but some are single berthed cabins with cot beds. The furniture is of mahogany and each first class cabin has a rug and is of unusually large size with a settee besides the two berths.

The arrangement of the cargo holds is clearly indicated on the drawings but special attention may be drawn to the fact that there are three insulated cargo spaces for the transport of refrigerated cargo. These are in addition to the numerous refrigerating chambers for the food consumed on the ship. 4,000 tons of cargo are carried.

In every respect, the *Aba* is one of the most interesting ships that has ever put to sea, and it is understood that the owners contemplate the construction of still larger motor passenger liners.

The Sun Shipbuilding Company's New Dry Dock

Forty-Two Ships Docked During First Six Months of Operation, Averaging One Vessel Every 3½ Days

The Sun Shipbuilding Company, although but five years old, has already established a record which places it high on the list of efficient shipyards and its advance into the ship repairing field last year has been attended with the same success that has placed it among the leading ship construction yards.

In 1920 the directors of this organization adopted plans for improvements to the plant with a view to broadening its activities to include general ship repair work. The prime requirements necessary to accomplish these results were a dry dock and wet basin of sufficient size to handle the majority of the vessels comprising the world's merchant fleet. A 10,000-ton dry dock, located at the head of a wet basin 960 feet in length with a mean average depth of 40 feet and a width at the river of 385 feet was decided upon as fulfilling the above requirements.

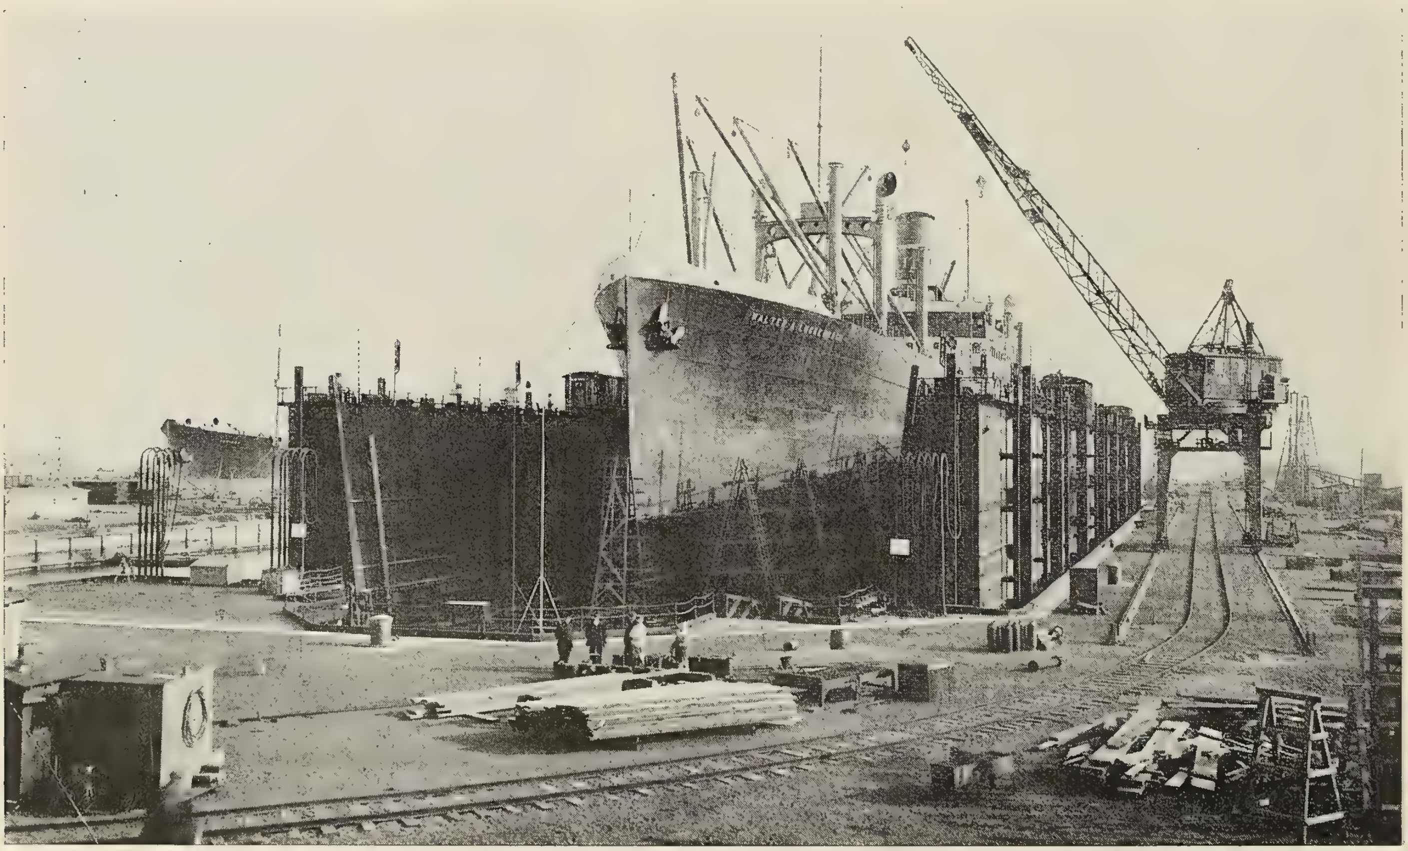
Dredging for the wet basin was started on July 8, 1920, and on December 1, 1920, work was started on the first pontoon for the new dry dock. On June 11, 1921, the new basin and dock were placed in commission and later in the day the first vessel, the Sinclair Navigation Company's tanker *Joseph M. Cudahy,* 10,600 deadweight tons, was docked.

Since then to December 1 no less than 42 vessels have been docked for painting, cleaning or bottom repairs, making an average of one vessel every 3½ days.

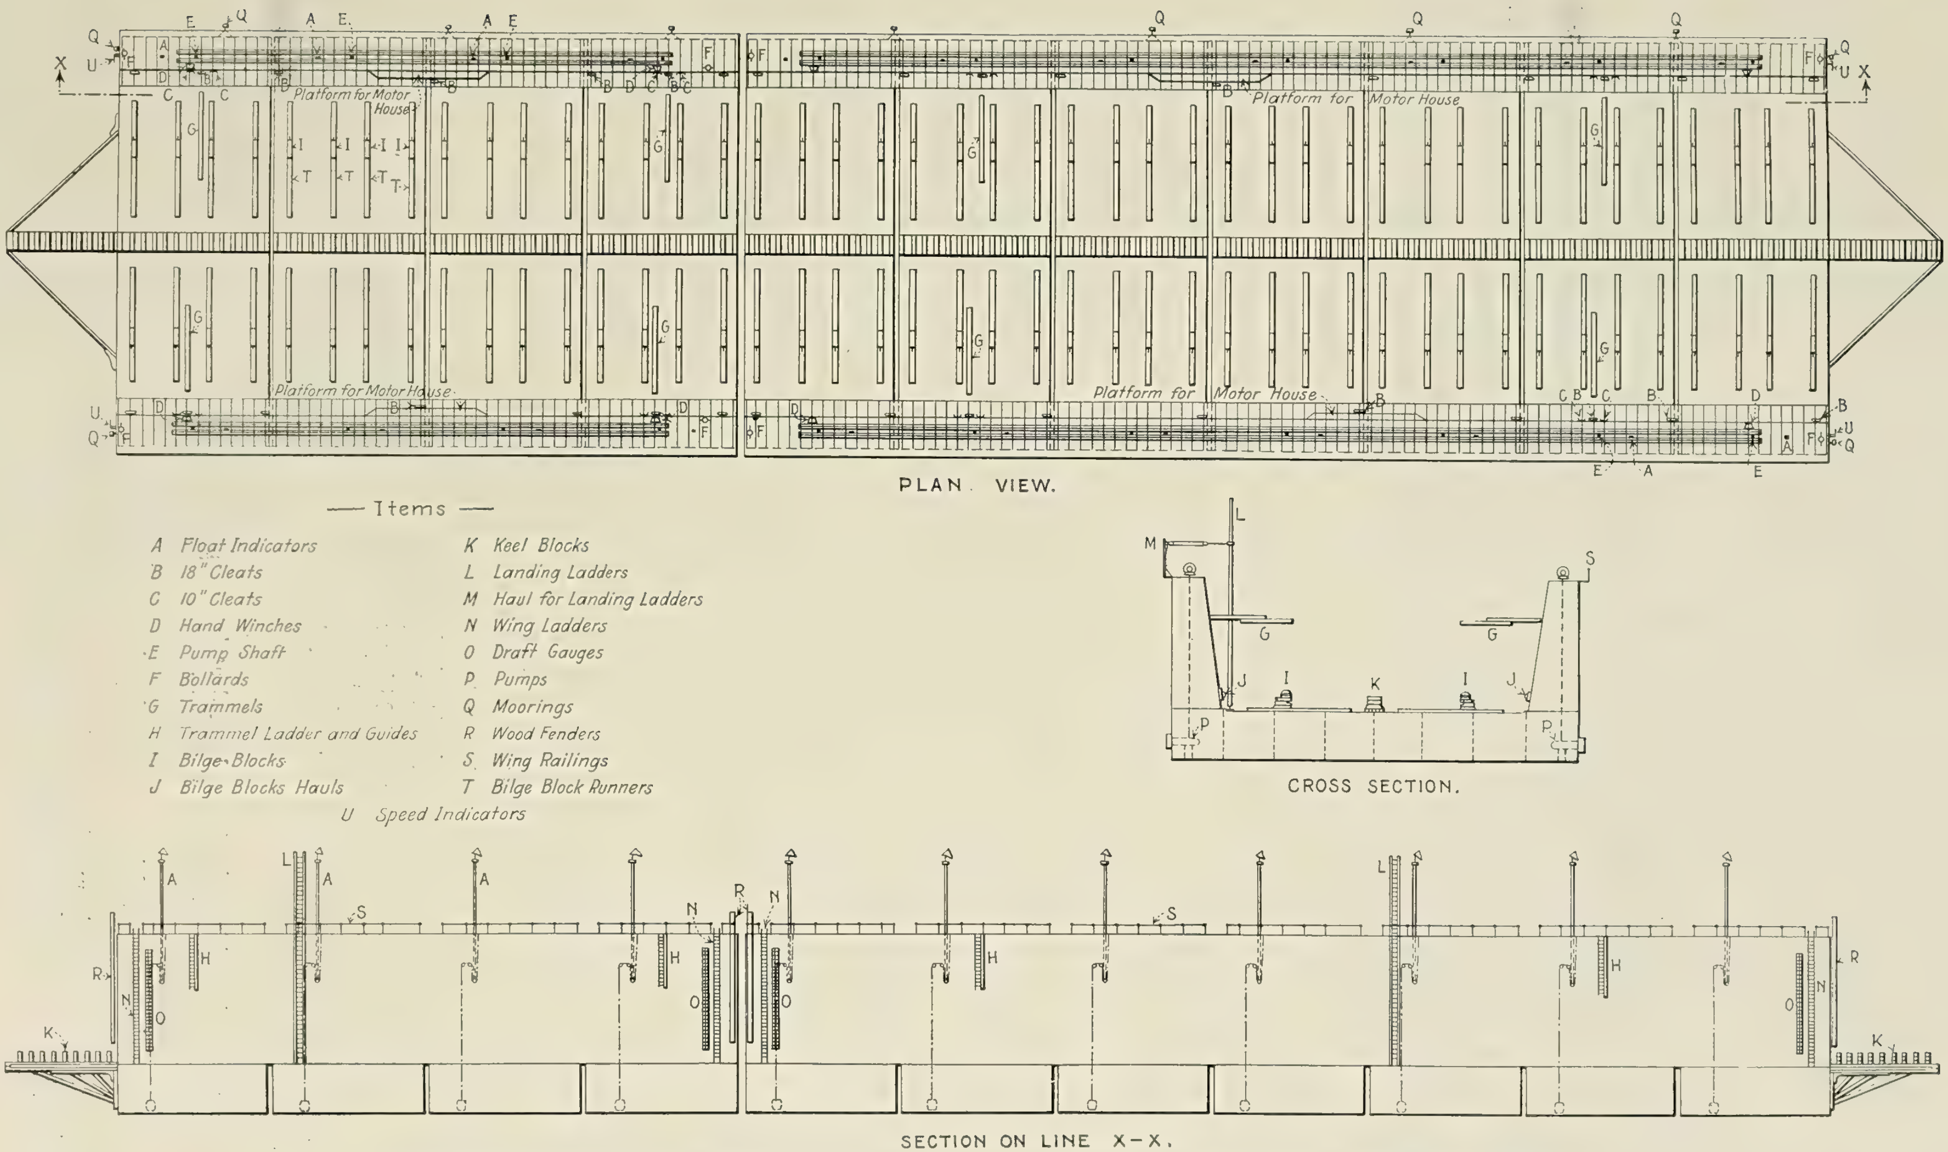
The Dock

The dry dock is of the floating type designed by William T. Donnelly, consulting engineer, 17 Battery Place, New York.

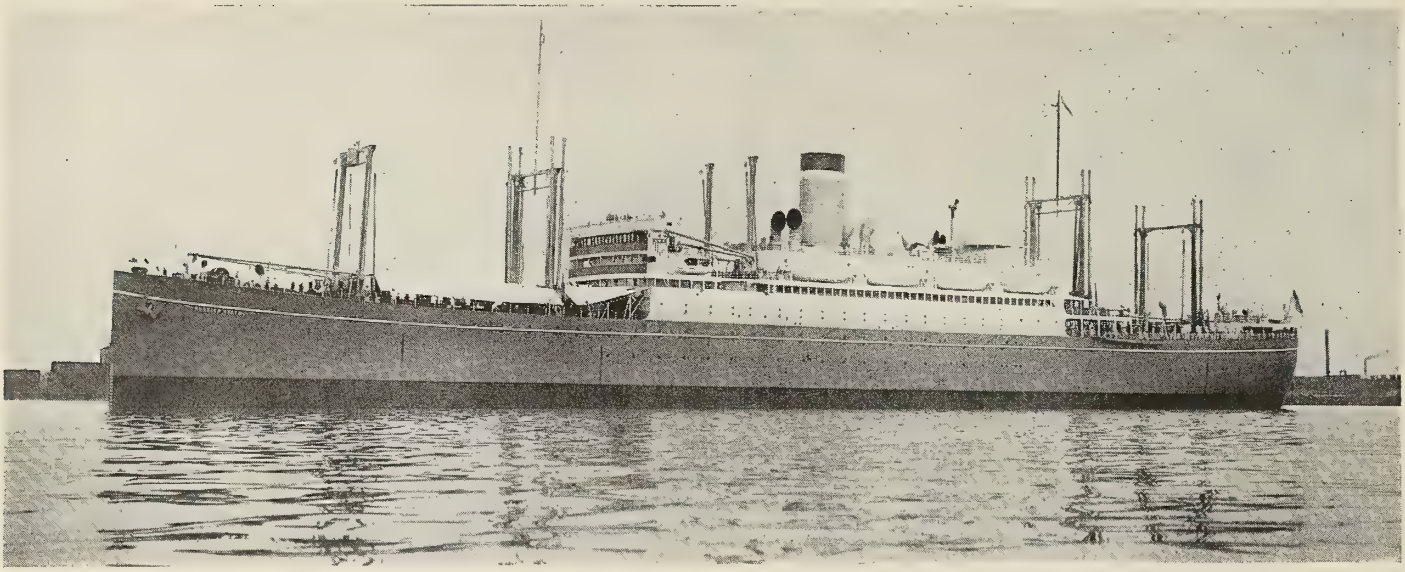
The general design consists of wooden pontoons of heavy spruce timber and continuous steel wings in accordance with the well known Donnelly methods of dry dock construction. An innovation, however, has been incorporated in the Sun dock in that it has been constructed in two sections.



View of Wet Basin at Sun Shipyard, Showing New 10,000-Ton Floating Dry Dock in Operation



General Arrangement of 10,000-Ton Donnelly Floating Dry Dock Built for Sun Shipbuilding Company



Passenger and Cargo Steamer Hoosier State

The first section, made up of 7 pontoons, is 323 feet long over the outrigger and the second section has 4 pontoons and a length of 197 feet over the outrigger.

Each section is a complete dock in itself and may be used independently of the other, the larger section having an actual lifting capacity of 6,400 tons and the smaller a capacity of 3,600 tons.

Sections Can Be Combined

Provision is made for tying the two sections together to form the big dock with a length over keel blocks of 522 feet 6 inches, a width over all of 110 feet and a rated lifting capacity of 10,000 tons. The dock is capable of exceeding this, however, and has an actual maximum lifting capacity of 11,000 tons. This will allow for docking a vessel of a maximum length of 560 feet, breadth of 78 feet and draft of 23 feet.

Each pontoon is 110 feet long, 41 feet wide and 13 feet 5 inches deep.

The wings are of steel construction 13 feet wide at the base and 35 feet high, topped with a working platform 10 feet 6 inches wide extending the full length.

Operation

The dock is operated by electricity.

In the bottom of each pontoon there are two 12-inch centrifugal pumps, one on each side. From each pump a shaft extends to the top of the wing and by means of miter gearing is connected to a shaft running the full length of the wing. This shaft on the top of each wing is geared to a driving motor located in a motor house at the center of the wing.

There are two motors for each section, one on each wing. The pumps in the large section are driven by two 200 horsepower motors and those in the small section by two 125 horsepower motors. Current is supplied from a station on shore and the operation of the dock is controlled from a house on shore designed to permit a clear view for the operator while docking and undocking ships.

Cables are also led from the control house and run on both sides of the wet basin, with outlet boxes located at intervals of 75 feet, from which current for temporary power and welding may be taken.

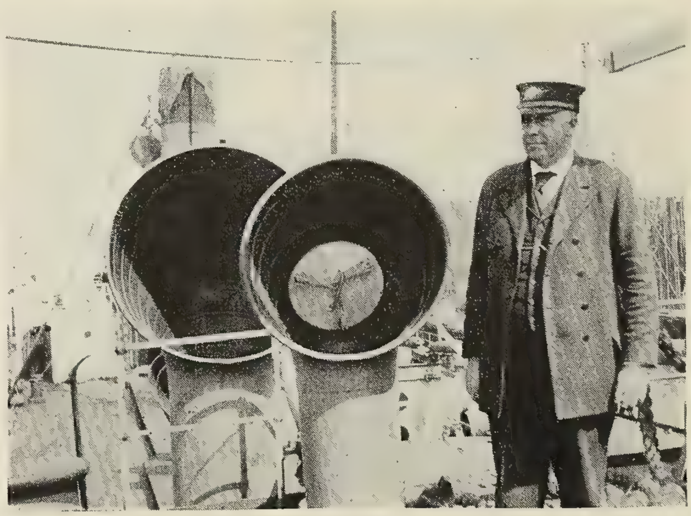
The new Sun dry dock fills a long felt need for such a dock on the Delaware River and the ports of Philadelphia and Chester. It was constructed in six months and eleven days, a record for this size dock and from present indications it bids fair to establish a record for operation as well as construction.

Passenger and Cargo Steamer Hoosier State Delivered to the Pacific Steamship Company

ANOTHER of the 535-foot Shipping Board passenger and cargo vessels has been delivered by the New York Shipbuilding Corporation, Camden, N. J. This is the *Hoosier State* which ran her trials on September 15 and has been assigned to the Pacific Steamship Company for operation. The vessel measures 535 feet overall and has a beam of 72 feet. She is equipped with twin turbines of 12,500 horsepower which will give her a speed of 17½ knots. Accommodations are provided for 280 first class and 194 third class passengers, in addition to a crew of 198 officers and men.

New Type Control for Ships' Ventilators

A RECENT invention for closing and opening ships' ventilators has been perfected and patented by the Ventilator Cap and Cowl Cover Company, Seattle, Wash. It is claimed that but seven seconds is required for capping and plugging one ventilator, and with the services of but one man the full complement of ventilators on an



Ventilator Cap Hanging in Cowl Ready for Instant Adjustment, Closing Vent Water and Air Tight

average size ship can be capped and plugged in fifteen minutes. In conjunction with the steam smothering lines, which are led into the holds for fire protection, the ventilator caps are useful, since the ventilators can be plugged quickly and thus allow the steam to produce a smothering effect almost immediately. Ventilation is necessary in cargo vessels to prevent sweating and damage from other causes, and with the new plug advantage can be taken of all favorable weather because it is possible to close the ventilators quickly at a change of weather.

It is stated that the cost of installation of this capping device while it is of a permanent nature is merely nominal, and the Ventilator Cap and Cowl Cover Company is planning to introduce this equipment through ship repair plants at the more important ports in the country.

Duration Time Watch for Studying Efficiency

For the purpose of facilitating the timing of industrial operations, the Mortimer J. Silberberg Company, 122 South Michigan Avenue, Chicago, Ill., has perfected an instrument designed to handle the timing of from one to ten production motions, up to five minutes in duration.

New Type Time Study Watch

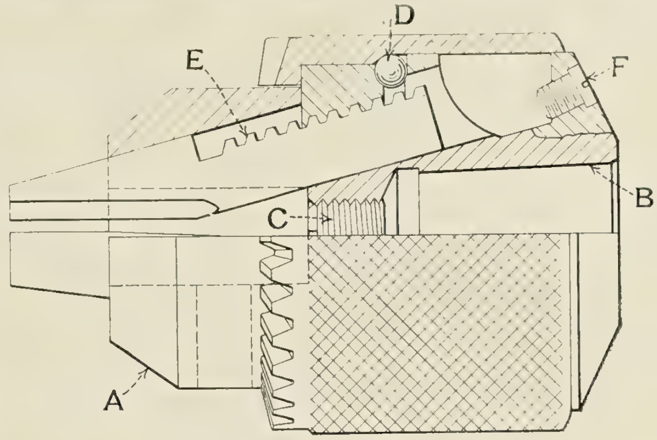
The instrument has three circles on the face of the dial, the outer circle being in red, the center circle in black and the inner circle in blue. The large hand makes a total revolution of 100 seconds, and the small hand in the center moves over a red, black and blue sector, thereby showing in which circle the large hand is operating.

All of the figures on the face of the dial denote production per hour, based on the timing of 10 operations. For example if 10 operations were observed to have elapsed in 20 seconds the figure under the large hand in the red circle would show 1,800 operations per hour, based on 10 operations having been completed in 20 seconds. If instead of 10 operations, one operation is observed to have lasted 20 seconds, then instead of 1,800 it would be necessary to point off one figure with a decimal, and the result would be 180 operations per hour, based on one operation being completed in 20 seconds.

If an operation is timed and its duration is 130 seconds, it will be noted that the large hand will have made one total revolution, and thirty seconds additional, and the small hand in the center of the dial will have passed the first sector, and show in the second sector, which is the black, and which denotes that the operation must be read in the black circle; and reading under the 30-second mark in the black circle the figure 277 will be noted. However, this figure being based on the observation of 10 operations, and only one operation having been timed in that period, it is necessary to point off one figure, and the result is then 27.7 operations per hour, based on one operation timed in 130 seconds.

Toothed Key and Sleeve Type Chuck

THE chuck of the toothed key and sleeve type manufactured for the past eighteen years by the Jacobs Manufacturing Company, Hartford, Conn., has recently been redesigned so that the proportions of the parts now make it more adaptable for general service. The body A is made of steel of a special analysis, deeply case hardened. Through a special process in this heat treating the taper hole B is left soft, fitting it for use on a hardened and ground arbor. This taper hole is ground with great accuracy. A hole is drilled and tapped through the center of the body and fitted with a threaded plug C which may be removed with a screw driver if it is desired to insert rods or other material through the chuck.



Jacobs Toothed Key Type Chuck

The taper hole on the chuck is of the same dimensions as those of previous designs. Each of the new chucks has been designed to meet the changed drilling methods of the last few years with relation to design, weight and capacity, all needless weight having been eliminated.

Ball bearings D inserted between the nut and the body reduce friction to a minimum making it possible to machine the thread E on the nut and the jaws with a coarser pitch than heretofore. Reduction of friction makes it possible to tighten the chuck with great ease, preventing undue wear on the keys, sleeves and other parts of the chuck at the same time giving greater gripping qualities.

An oil hole F inserted in the upper end of the chuck makes it possible to lubricate all of the working parts. One half the pressure on the key in tightening the chuck will produce the same results as in chucks of the previous design and the change in pitch of the thread on the jaws has resulted in reducing by one half the number of turns of the sleeve necessary to tighten or loosen the chuck.

Senate and House Committees Plan Joint Meetings

THE Senate committee on commerce and the House committee on merchant marine and fisheries have planned for a series of joint meetings at which officers of the Shipping Board and of the Emergency Fleet Corporation will be heard. Chairman Lasker has already appeared at one or two such meetings, which are held in executive session, and in a way they are a substitute for the general Congressional investigation of Shipping Board affairs which have been several times proposed.

W. J. Love, vice-president of the Emergency Fleet Corporation, has decided to lay before the Shipping Board for action the practice of steamship companies in the Intercoastal Conference cutting rates below those agreed on in conference.

Design and Construction of Passenger Steamers*

Summary of Problems Confronting the Designer of a Modern Liner — Details of New American Passenger Ships — Standardization

By E. H. Rigg†

THE great problem of today is to design and build ships that can be made economically satisfactory. We are still short of passenger ships; the lack of new orders and holding up of old ones is solely due to economic conditions, high first costs and inability to pay the rates necessarily asked, chiefly the former.

The large number of our recently completed passenger ships which have gone or are about to go into Pacific Ocean trade calls for comment. Of the sixteen 535 footers and the seven 522 footers, representing a gross tonnage of some 300,000, twelve of the larger and three of the smaller have gone into service on the Pacific; of the larger, two are still to be allocated, which indicates that the fleets to which allocations have been made are temporarily satisfied. The Pacific thus gets 67 percent of the tonnage, and there are other indications that our Pacific trade will be large—our interest in China and its development, our nearness to her markets compared with Europe. The Philippine and the Hawaiian Islands make for commerce with the Pacific coast; our Australian and Japanese trade also calls for passenger and freight services.

Then, too, South American trade presents an opportunity awaiting revived foreign trade, improvement in the exchange rate from the foreigners' point of view, improved exporting methods on our part and the working out of the recent foreign trade financial legislation.

Passenger Steamers for Sheltered Waters

Perhaps nowhere in the world are there such opportunities for lake, bay, sound and river navigation as in America. The problems are not as complicated as are those of the ocean; draft is usually limited, and lines adapted for high speed in shoal water are not the same as for deep water. Ports are closer and bunkers carried are lighter; fresh water from overboard is often available for boilers, if not for drinking. Cargo is generally carried in relatively small amounts, largely on deck rather than below. Fire risks are severe in these ships and must be seriously studied and minimized. In rivers and canals, bank erosion must be guarded against, and here the experimental tank has come to our aid in studying wave making. In some recent Hudson river vessels, in particular, wave making has been notably reduced, enabling greater speed to be maintained for the same erosive action or less of such action for equal speed.

Many of these vessels in the past have been built with too little beam for satisfactory stability results; top decks have been increased or added in order to crowd on more passengers, the accident point having been found in more than one instance, notably the *Eastland*, in recent years. Some river steamers have found it necessary to set back the rails, thus limiting the passengers who can crowd top decks; also in boats traversing water with points of interest first on one side, then on the other, water ballast chambers in the wings have been fitted so that the engineer can fill the same on the off side and empty it again after passing the particular point.

Paddle-wheel propulsion still holds its own for this type; the experimental tank is invaluable for correctly locating the wheel center to avoid disaster due to wave profile and wheel not meshing.

Paddle wheels have been recently severely put to it to hold their own with screws working in tunnels as a means of propulsion for shallow draft vessels. We have also seen a revival in proposals made many years ago which looked to the fitting of fixed guide blades abaft the revolving blades to recover some of the energy of the propeller race. It can be said that tunnel screws have definitely established their claims.

Passenger-Refrigerator Trades

The carriage of meat, fruit and dairy products in cold storage has become a very large trade during this generation. Perhaps the chief feature which leads to the passenger-refrigerator ship is the speed desirable for refrigerator ships—the less time on the voyage the better. Also, these cargoes are bulk rather than deadweight cargoes, which means that larger ships are needed for a given weight. Both these considerations lead to the desirability of increasing the revenues by carrying mails and passengers.

There are also some large meat carriers fitted with accommodations for passengers, a valuable revenue being derived therefrom to pay for the speed in excess of 11 knots, about a cargo carrying economical speed limit for vessels of moderate to large dimensions.

Trend of Design; Ocean Passenger Ships

As an indication of this, the following classes of ships designed in part and estimated on, since January, 1918, by one large shipyard in this country, may be of interest:

Length between perpendiculars, feet	Speed, knots	Cabin passengers	Deadweight
400	15	100	4,350
600	18	1,460	15,000
450	23	410	3,700
500	16	250	9,000
550	15¾	1,830	8,650
475	14½	445	5,530
360	13½	50	4,100
450	16	255	6,000
400	15	200	3,900

Several of these ships had third class and steerage passengers in varying numbers. These quarters were portable to a large extent, so only the first and second class quarters and permanent third class cabin accommodations have been listed above, thus giving a better guide to the characteristics of the vessel. In the 600-foot ship, accommodation for 700 third class passengers in permanent cabins is included; also in the 550-foot ship 1,160 such third class are included. The list thus gives the real cabin accommodation, whether first, second or third.

The 23-knot ship was primarily intended for a coastwise run, but also for transpacific, so that she is correctly rated as an ocean-going ship, though whether the full 23 knots would be maintained on a deep sea run is problematic.

The average length works out at 465 feet, a very modest figure for nine typical passenger ship designs, and, omitting the 23-knot ship, the speed averages 15½ knots. It would seem fair to regard the high speed of 23 knots in a 450-foot ship as quite exceptional. It is worth noting that 15½ knots is quite modest for a 465-foot ship and that it checks up with the tendency noted above. These ships are uniformly of the shelter or shade deck types with ample superstructures amidships and generally with forecastles.

*Paper read before the Society of Naval Architects and Marine Engineers, New York, November 18, 1921.

†Naval architect, New York Shipbuilding Corporation, Camden, N. J.

Fully half these inquiries were from foreign owners, an encouraging sign.

Besides the above listed vessels, other inquiries not involving detailed design work were received; they lined up well as to type with those given and do not change the indication of the trend.

As regards proportion, the old and lingering tendency to narrow beam is at last giving way; it is not going fast, but it is yielding to two influences; the old ship that capsizes when handling light in harbor, unless ballasted, evidently is a nuisance and has plagued a good many people. The war has served to emphasize a tendency already to be seen by those on the inside, and that is to give more metacentric height and listen less to the discomfort of passenger talk that was so prevalent. Personally I feel that you have to go to metacentric heights far higher than the prevalent 18 or 24 inches in order to get appreciable discomfort; in other words, get all the data you need by studying stability and rolling features in successful ships, then adopt a G. M. about twice pre-war standards and you will have a ship that is not too stiff.

The other cause leading to more beam is the finding by Admiral Taylor and other investigators working in the experimental model basins, to the effect that more beam can often be given a ship and enough coal saved by fining up (for the same deadweight) to pay for the little extra steel weight generally involved. In other words, the bugaboo of narrow beam is under investigation and is getting to be in a bad way. It must, however, be noted that stability considerations due to the flooding of a damaged ship point to caution in increasing beam. War experience has given us a large volume of data concerning the behavior of flooded and sinking ships, and this, intimately associated with subdivision lessons, will ultimately give us safer all-around ships.

The strength of our position in cargo-carrying tonnage is not yet reflected in the passenger-carrying trade, but with our operators in the passenger trades encouraged by the delivery of new ships and by the reconditioning of captured vessels, the outlook for the future is brighter than it has been for at least two generations. There is also some encouragement for builders in that the void in their yards caused by the prevailing lack of cargo ship orders may be partly filled by orders for passenger ships. It seems safe to forecast that passenger ship construction will figure somewhat prominently in our bigger and best equipped yards during the next few years, particularly when it is remembered that a considerable number of ships now running would, but for the war, have been out of service ere this and that they will need replacement just as soon as practicable.

Bulkhead Subdivision

This subject has been very much to the front since the spring of 1912, when the world was shocked by the disaster which befell the *Titanic*. As the question stands today we have the results of the international convention to work on together with the British Bulkhead Committee's Report, followed up by such papers as those of Abell, Benvenuti, Chamberlain, Denny, Dickie, Donald, Finlay, Foster-King, Gatewood, Hovegaard, Lovett, Orlando, Robb, Wall, Webster, and Welch. We also have governmental and classification society instructions to guide us.

The war has taught us that a spacing of 40 feet is about the minimum desirable to cover war risks, as a closer spacing gives torpedoes a good chance of blowing out two bulkheads at one explosion. Our Pacific coastwise passenger steamers should have more attention in respect to bulkheads. It is proven that good bulkheading will save many a ship altogether; also that the ones it does not finally save it will often keep afloat for hours and thus give full time for rescue work to be made effective.

One-Class Liners

As it has developed since the war, this is a relatively new idea and one which has much to commend it; on a large, high-speed liner the *de luxe* accommodation very naturally and properly occupies the best of the available space. Second class is generally aft and quite limited as to public rooms and promenades. Third class comes in below first, and the forward deck is the airing space, this being frequently so airy that none but ablebodied seamen can navigate with safety.

What better way to solve the problem than to carry the passengers willing to pay the rates on the larger and faster mail steamers and to give the benefit of the best parts of other ships to people willing to pay cabin rates for passage in slower ships, run at lesser operating costs and carrying relatively more freight. The idea works out well in connection with the moderate sized ships built since the war; it gives greater flexibility in operating fleets, taking care of seasonal changes in business conditions.

Another point which should not be lost sight of is that the one-class liner works in well with moderate first cost of ship. The one-class ship, or rather the ship with absent class distinctions, is something that deserves to succeed, and let us hope to see it do so.

Length

In 1912 Mr. J. Foster-King presented some very interesting diagrams to the International Congress of Navigation in Philadelphia. These pre-war indications of the trend are extremely valuable at this time; the diagrams are produced to 1920 and thus enable performance and estimate to be compared. For the largest type of North Atlantic liner, the 1,000-footer was indicated; in the *Aquitania* and *Majestic* (ex-*Bismark*) we find pre-war justification of the forecast. Coming down to the longest types for general first class passenger service and selecting some fourteen of the most noteworthy post-war designs actually launched, we find an average length of 585 feet, the greatest being 650 feet and the smallest 505 feet—five only being 600 feet and over. Mr. King's curves gave 775 feet for Atlantic liners, excluding the leviathans, and 650 feet for general first-class liners; it is clear that the 1912 outlook has not been realized, a point also clearly brought out in several other directions; the fact that the 585-foot average includes several Atlantic liners tends further to show the reduction, the figure with which it should be compared being intermediate between 650 and 775, in a ratio difficult to get at.

It seems reasonable to say that large passenger ships have been shortened by 100 feet from considerations arising out of the war. The chief influence at work is the high cost of ships, which makes it a serious question with owners as to whether they can charge passage rates high enough to realize on their investment without killing the business of passenger carrying by reason of the inability of people in sufficient numbers to pay such rates.

The Thousand-Foot Liner

The long spell of idleness at her dock of the *Leviathan*, after invaluable troop service, is rather a damper on 1,000-foot ardor; nevertheless, it remains a fact that a vessel of this length was well in sight when the war broke out. At least one design has been seriously started and pushed to the point of a study of schedules, terminals and rail facilities,

of a full set of outline plans, of extensive calculations and of detailed lay-out out of proposed propelling machinery.

This design contemplated going to Panama Canal lock limiting sizes at one step; it is not necessary to say that the two ships would run between New York and London, starting and arriving at deep-water harbors at each end and with rail connections to New York and London.

It can be safely said that the engineering features, especially when high tensile steel is used, present no difficulties which cannot be met. The problem is one of economics entirely. Is the route able to support such liners without government aid in some form? If not, what justification can be advanced for claiming such aid?

We can, as shipbuilders and engineers, say that, as far as our profession is concerned, we stand ready to furnish the ship and her propelling machinery just as soon as other considerations justify such a vessel. As a matter of record and interest a few particulars of the design as it stood in its earlier stages may be of interest:

Length, over all	1,000 feet
Breadth	105 feet
Depth	76 feet
Deep load draft	38 feet
Speed at sea, knots (depending on weather)	30 to 32
Shaft horsepower (maximum)	150,000
First class passengers	1,100
Second class passengers	800
Third class passengers	1,400

The propelling machinery at first contemplated was electric drive; with the large battle cruiser *Hood* at sea, the path has been opened to the full consideration of the claims of a geared turbine drive.

The oil fuel required for a round trip is in the region of 11,000 tons. This would be too much for the ship to leave this side with; the answer would be to leave here with oil for the trip over and halfway back, taking in oil for the other half of the returning voyage on the other side before leaving. At full load this vessel would have a total deadweight of about 12,000 tons. There would be no freight as is generally understood; mail, bullion and express matter, yes; also such small consignments of special freight that could be handled during the time necessary to refuel and reprovision the ship at each end.

In the early days, when this length was first proposed, the scoffers, technical and otherwise, were legion. Not so now; technical scoffers at once merely proclaim their ignorance. On the financial side there is ample room for hesitation and there the matter must rest for a while, to be taken up again as the world recovers from the effects of the war.

Depth and Draft

This subject is one calling for special mention. It can be stated at once that the drafts adopted for large liners are not those that the naval architect would choose, if he had a free hand; neither are they the ones dictated by considerations of the limitations of steel as a shipbuilding material. Terminal harbors and canals are the main deciding factors. Suffice it to say that the economics of the ship can benefit by increased draft up to the point where such increase imposes excess costs on harbor authorities, which would have to be passed back to the ship in the form of increased and excessive harbor charges.

A really first-class harbor should nowadays have a depth of at least 40 feet, and Lord Pirrie advocates 45 feet; with such depths and corresponding drafts of about 37 feet 6 inches to 42 feet 6 inches economics of transport are available. Mr. J. F. King's forecast in 1912 is worth noting; his figures gave a 1920 draft of 36 feet 6 inches for Atlantic liners and for average passenger ships. The predicted Suez Canal depth of 30 feet came very close to being a mean draft for such ships, which showed steady increase up to a 25 to 34-foot range. Draft increases relatively and actually more slowly than length, it is hardly necessary to say.

The Panama and Suez canals are bound to exercise a profound influence on the drafts of passenger liners, the figures for which now stand as follows:

1. *Panama.*—A minimum depth of 40 feet in the canal, with 40 feet in the Atlantic and 35 feet in the Pacific approaches at mean low water, which means an available draft of about 38 feet.

2. *Suez.*—At present the available depth is 32 feet and permissible draft is 30 feet; the authorities are dredging for 34 feet 6 inches and 31 feet figures respectively.

It is to be noted that Suez has gradually been deepened by dredging from 19 feet in 1870 to 32 feet in 1920.

Liners of the future will probably not be able to avail themselves of all the draft economically desirable, for we are now approaching the region of excessive dredging costs in certain harbors.

Another big factor in restricting draft is the River Plate; many vessels now trading there on a 26 feet 6 inches limit could well have been designed for 30 feet.

Speed and Power

Looking back on the not so distant days when it was necessary to plead the advantages of experimental tank work, it is gratifying to reflect on the conditions of today. In addition to resistance and estimated horsepower curves, the experimental work now being done on model propellers, both in free water and behind ship models, calls for commendation. This is a field that has been opened up comparatively recently.

In addition to deep water conditions, attention is given to shoal water problems, so important in connection with inland navigation. It is known that lines suitable for deep water are not necessarily good for shoal water.

Coming to passenger liner speeds, before the war we had reached 26 knots for all the way across the Atlantic, this in the *Lusitania* and *Mauretania*. In the later Cunarder *Aquitania* we see a reduction to 23 knots, while the large White Star boats ran in the neighborhood of 21. About the maximum for the long routes to the Cape, India and Australia was 18 knots.

Moderate speed will be a feature of new construction for a while. The average speed for fourteen post-war designs for all trades is about 16½ knots with a range of from 14 to 18 knots. New ships on the North Atlantic average up well with those on the general routes of world travel, instead of the accustomed 21 to 23 knots of the old days. In the attainment of better results, the competition in systems of propulsion does, and will to a greater extent, contribute to a lower consumption of fuel per horsepower. The problem is threefold—lower resistance, better wheels and more economical power plants.

Speed has an effect on design that is not clear at first glance. The piling up of deck houses is a noteworthy feature of many modern vessels. High deck houses are one solution of the ventilation question that cannot be ignored, for we all like an airy room.

The claims of the watertube boiler over the Scotch for high-speed ships have made good to such an extent that they will feature more largely in future ships.

The Cost of High Speed

Apart from the initial cost of the machinery necessary to obtain high speed, the fuel bills become very high. For example, consider a 750-foot Atlantic liner of varying speeds from 15 up to 30 knots; such a ship would have a beam of about 90 feet and a deep draft of 36 feet. Call the voyage 3,000 miles, which gives a round figure close enough for our purpose. Remember, too, that as speed goes up cargo carrying ability goes down and passengers, mail and express mat-

ter become ultimately the sole sources of revenue, outside subsidy. The figures are about as follows:

Speed at Sea (Knots)	S. H. P.	Total Dead-weight	Cargo Dead-weight	Oil Fuel, One Way (Tons)	Cost of Fuel, One Way
15	16,000	29,000	26,500	1,450	$26,100
20	38,000	23,000	19,400	2,550	$45,900
25	73,000	14,000	9,000	3,900	$70,200
30	113,000	5,800	.....	5,000	$90,000

Such a vessel would carry some 600 first, 450 second and 1,000 third class passengers and would be quite big enough for speeds all the way to 30 knots. It is seen that the 30-knot ship carries nothing but passengers, mails, stores and bunkers, which is the logical outcome of this investigation. The above table will show that, with cargo capacity falling from 26,500 tons to nothing and fuel costs rising from $26,100 per voyage to $90,000, the economics of the large ship are not easy. It is clear, however, that the greater number of voyages per year for the 30-knot ship must also be taken into account. This may be summarized somewhat as follows:

Speed of Ship (Knots)	Days at Sea, One Way	Days in Port, at Each End	Days for Single Trip	Single Trips Per Year	Passengers Per Year, at 85 Percent Full	Cargo (Tons) Per Year
15	8 1/3	9	17 1/3	17.3	30,270	3,897,000
20	6 1/4	7	13 1/4	22.6	39,550	3,726,500
25	5	5	10	30	52,500	229,500
30	4 1/6	3	7 1/6	42	73,500	....

The compensations coming to the fast boat show up in this table; she will carry more than twice the people per year at, naturally, much higher rates per person. It is also clear that the 15-knot ship does not deliver enough extra freight to compensate for the fewer and lower rate passengers carried. With everything lined up properly, the 30 knotter will make twenty-one round trips in a 300-day working year, *i. e.*, a round trip every two weeks. Two such ships, laying off during the two bad months to avoid the worst weather, could command the cream of the travel.

They are not excessive in size, and even if they only make twenty round trips per year, due to miscellaneous bad weather and sometimes taking the longer southern route to clear ice and fog, such ships equipped for first and second cabin only would each average 45,000 passengers per year, which at, say, $250 per person comes out at $11,250,000 against a fuel bill of $3,800,000, which is not so hopeless. May I commend this 750 footer as a step well worth considering in our further progress towards the solution of the problem of the modern Atlantic liner?

Another interesting angle to the speed question is that of increasing speed in vessels of moderate dimensions. A maximum speed-length ratio of unity has been a general guidance rule for ocean passenger ships for many years. With lighter machinery, oil fuel and other advances, the speed question again becomes one for renewed study and discussion.

The following table shows the fuel savings possible for high speed, moderate dimensioned vessels:

Length of ship (feet)	S. H. P. at 25 knots	S. H. P. at 30 knots
600	56,000	137,000
700	64,000	119,000
800	68,000	131,000
900	80,500	153,000
1,000	91,000	163,000

These figures represent smooth-water powers plus 10 percent for the 25 knotters and plus 15 percent for the 30 knotters. The dimensions dependent on length follow average merchant practice, except that the beam on the 1,000 footer has been limited to suit the Panama Canal lock dimensions to 102 feet.

Destroyers attain a speed-length ratio of 2.00, but it cannot be claimed that they attain it with comfort and safety except in quite moderate weather. European cross-channel steamers obtain a ratio of 1.50 with greater safety and comfort than destroyers; where the line must be drawn for the North Atlantic is our problem. The ships listed above cover a range of from 1.225 for the 600 footer to 0.95 for the 1,000 footer at 30 knots. The *Mauretania's* figure is 0.95. From this it is submitted that the 750-foot ship of 30 knots as proposed above is practicable, providing the fore ends of the ship and of the midship deck erections are especially designed and strengthened, with a view to avoiding deck damage in weather not otherwise severe enough to make slowing up necessary. All fittings and deck openings before the bridge would need to be of special design.

The question of powers to be expected, if very fast liners of warship types were to be adopted, is interesting and is another angle of the question that should be investigated. The proportions and speed both render large and high deck houses out of the question; the passage would be short and promenades would have to be arranged on the quarter deck aft and on one deck amidships well protected from spray. Fast yachts have already been built on destroyer lines, so that liners on cruiser lines are only a logical step and one that has been discussed before. The speed has been taken at a 20 percent advance on previous general practice; the time on a 3,000-mile run in moderate weather is also given. In the powers given a 10 percent margin for sea speed is allowed over a measured mile performance. The bunkers work out at quite large figures. It can be assumed that oil fuel is obligatory, coal handling would be well-nigh impossible both on board and alongside. These bunker capacities are high, but not impractical. Taking only first class passengers and allowing 1½ per foot of length, we get the numbers given in the table. The longitudinal coefficient is 0.58 and the mid area 0.90 for all lengths. It is seen that the increase from 29 to 36½ knots cuts one day off the voyage.

As regards weights, it is clear that warship practice rather than merchant would have to be followed for machinery design; the absence of armor, torpedo protection; battery and ammunition weights being utilized on deck erections, passenger accommodations and bunkers.

Mean displacement	10,000	20,000	30,000	40,000
Full displacement	11,500	22,750	33,850	45,000
Length, feet	585	735	850	930
Breadth	58.5	73.5	85	93
Mean draft	19.5	24.5	28	31
Mean speed, knots.....	29	32½	35	36½
Total E. H. P.........	27,500	61,000	97,250	135,000
Total S. H. P.........	50,000	112,500	177,500	247,500
Oil for 3,000 miles.....	2,300	4,700	6,800	9,100
Days on voyage	4.31	3.85	3.57	3.42
Passengers	875	1,100	1,275	1,400

The Beginnings of Our Postwar Passenger Fleet

During the war our dependence on allied troop transports led to the ordering of some twenty odd large and some thirty odd moderate sized transports at Newport News, Bethlehem, New York Shipbuilding Corporation and Hog Island. None of these vessels was completed prior to the armistice, and some were subsequently cancelled, mainly the smaller ones at Hog Island. These ships are now in service, some as troopers (Hog Island) and some as passenger liners, with the latter of which only are we here concerned. Of the larger ships, Newport News built two, Bethlehem five, and New York Shipbuilding Corporation nine, a total of sixteen ships of some 225,600 gross tons; the smaller ships number seven, all built by the New York Shipbuilding Corporation, totaling some 73,800 tons gross.

Their outline particulars are as follows:

Item	Old North State class	American Legion class
Length, overall	522′ 8″	535′ 2″
Beam, molded	62′ 0″	72′ 0″
Depth, molded	42′ 0″	50′ 0″
Load draft	32′ 3″	30′ 7″
Corresponding deadweight.	13,000	11,400

Item	Old North State Class	American Legion Class
Sea speed, knots	14	17½
Shaft horsepower	.....	12,000
Indicated horsepower	6,500	.....
Boilers (oil fuel)	Scotch.	Watertube.
Motive power	Reciprocating engines.	Geared turbines.
First class passengers	78	260
*Third class passengers	.....	300
Gross tonnage	10,540	14,100
Crew	117	134
Bulkheads	11	13

A few words on the outstanding characteristics of these ships may be in order:

1. *Passenger accommodation.*—This is unusually spacious. Large rooms, beds rather than bunks, numerous private bathrooms, and ample public rooms are noticeable, especially in the larger vessels. Running hot and cold water is supplied in the rooms.
2. *Cargo handling.*—Both in the number of hatches and in the facilities at each hatch, this feature is especially well cared for, quick turn around being thus possible.
3. *Unusually close subdivision.*—Being laid down as three-compartment ships for troop service in the war zone, these vessels are all very well bulkheaded, especially the larger ones, where cargo is not so important.
4. The interior decoration has received greater care than usual, our colonial period supplying the dominating scheme of architectural effect. This has been modified in certain spaces, such as the verandas, tea rooms and smoking rooms. Furniture, decorations and draperies were from designs by W. & J. Sloane of New York. The architectural plans for the larger ships were mainly by the Bethlehem Shipbuilding Corporation and for the smaller ships entirely by the New York Shipbuilding Corporation.
5. Unusually large steaming radius to enable Pacific Ocean and South American trades to be adequately negotiated.
6. The similarity of bow and stern is unpleasantly noticeable, this being an inheritance from war days.

Interior Decoration

The first requisite from the point of view of the passenger, after that of the general good or bad repute in which the line and ship he sails on is held, is that the general arrangement of the accommodations shall be such as to contribute to his comfort—enough promenade space and open decks for games, ample ventilation at all times and heat in winter, well-arranged staterooms and public rooms, access to all parts under cover. An essential factor in all this is the interior decoration. As in Pullman cars, so in ships, we have happily gotten away far from the days of heavily applied ornamentation. In ships it has been realized more and more that good interior architecture and decoration do not necessarily involve additional expense, or rather expense beyond an immediately appreciable return in the enhanced reputation of the vessel in question in attracting passengers.

Of the later periods which lend themselves to ship decorative architecture the Tudor and Flemish are found most frequently in smoking rooms; the periods of Louis XIV, XV and XVI of France in the music rooms, lounges and galleries. From classic and Gothic in lesser amounts we pass on to a wealth of the Renaissance of Italy and of France, to the English and Dutch evolutions and lastly to our own Colonial, the keynote to the decoration of our postwar ships of the *American Legion* class.

We have heard lately of ships that were overdone in the lavishness of their appointments. Let ships be designed each for their own trade, with due consideration to climates passed through, to the likes and dislikes of the people carried, to the length of voyage. A rational answer to these questions will settle both the decorative and elaborateness questions.

*Two of the smaller ships are being fitted for third class in the top 'tween decks.

Extent of Arrangement of Public Rooms

The arrangement which works out best in ocean going ships gives dining rooms on the lowest passenger deck with galleys and pantries around the casings and extending full width, the other public rooms being arranged on the top deck, opening one from the other and with wide passages or galleries between, enabling the best all-round result to be obtained. A dome over the dining saloon with exhaust fans is a most important contribution to comfort, coolness, lighting and decoration.

In the larger steamers the old-time narrow passage is giving place to the gallery between public rooms. This feature enlarges the scope of the living quarters, provides library, reading and writing facilities, besides giving ample communication under cover for use during the evening or during bad weather.

Promenades

Many ships sacrifice this feature to piling in the maximum possible number of staterooms, obviously to increase revenue. The liner, to be popular, must have good open decks for lounge chairs, walking and games, with decks adapted for outdoor sleeping on tropical runs.

Outside Rooms

In smaller ships all rooms can and should be outside rooms, *i. e.,* with ports or windows opening direct to the outside air. As ships get bigger our difficulties increase; the "Bibby" room is the popular solution, the inside room having a narrow passage leading past the outside room to a port. For vessels navigating sheltered waters the transverse berth greatly helps the designer of good passenger accommodations, but for sea going ships, the fore and aft berth, with only occasional exceptions, is the rule.

Single-berth Rooms

No doubt this is a feature appealing to all people traveling alone. A most ingenious plan that can be used in all vessels, particularly in those with ample 'tween-deck height, is that of placing two berths over each other, but so stepping the dividing bulkhead that one berth is in one room and the other in another room; in one room there is a lower berth only and in the other an upper berth only.

Details of Construction

Standard transverse framing continues to be the general rule for passenger ships. Wide-spaced framing is often adopted in order to get a spacing that suits details of accommodation better. If pushed to extremes, framing too deep for good hold capacities may result, besides very heavy shell plating: in way of machinery, deep framing does not affect capacity; carefully applied, it can be made an advantage. Longitudinal framing has not the same strong hold as in oil tankers and in long shallow vessels of all classes; vessels for rivers, etc., will always do well to consider longitudinal framing, but for deep-sea passenger vessels, with many decks, its advantages are not so clear.

Cruiser sterns for twin (and above) screw ship have solid merit in improving stability and speed performances. For single screw ships they are generally a bit of a misfit.

Electric arc welding has found a definite place in shipyards and there is ample room for a welding department in any big yard to work on details.

Wooden decks inside quarters are well nigh a thing of the past in ocean ships; there are several satisfactory plastic deck coverings for all interior spaces other than those generally cemented and tiled. There are also several forms of cork flooring which give good results. Parquet may be desirable for inside dancing spaces. Wooden decks are still premier for open deck spaces over quarters and for promenades.

In order to shorten turn around in port, either ship or dock, and sometimes both, have to be better equipped with cargo gear than was only a short time ago considered proper. The *Old North State* and *American Legion* classes fully bear this out, their twin derrick systems and numerous hatches having been commented on in every port visited. It should be noted that their close subdivision accentuates this feature.

The recent revisions of the rules of all the classification societies have placed in the hands of the shipyards methods of designing structure and details which enable much quicker and better work to be done.

Joiner work is not so dependent on wood for panels as formerly; as with sanitary floors, so with paneling, there are now on the market several satisfactory composition boards, and panels of these, mounted directly on the tongue and groove partitions, enable the two sides of a bulkhead to be fashioned to suit the furniture to much better advantage than with ordinary panels.

Lighting, heating and ventilation have improved of late; steam heat is largely replaced by electric radiators, which are particularly adapted for individual room heating in association with a thermo-tank system raising all the air to about 60 degrees, leaving the balance required to electric radiators.

With oil fuel, piping problems become more complex; the air escapes from the amidship tanks are sometimes difficult to handle in way of passenger spaces, an excessive possible head on the tanks being only avoided by taking them out through the shell. Oil fuel galley ranges are also a modern touch in oil-burning ships.

Communication and indicating devices get more complicated, fire-alarm systems, pneumercators, gyro-compass systems and submarine bell listening devices are among the newer modern tendencies.

Better bulkhead subdivision has helped fire protection; with alternates carried up to the top decks, modern ships have been afforded a much better chance of confining and subduing a fire.

The extra boatage now fitted on passenger ships has given trouble. Better bulkheads argue for less boats, though "boats for all" is rightly the generally recognized minimum acceptable. The writer feels that more rafts might well be allowed, especially where bulkheads are good.

Compulsory air ports on the lowest passenger deck might well be reconsidered.

The extent to which oil has been substituted for coal as a fuel calls for comment. Lloyd's returns indicate that 22½ percent of the world's total gross tonnage uses oil for propulsion, as compared with 3 percent in 1914, a stupendous increase and one that is mainly in vessels of American registry.

Standardization

The British Engineering Standards Association has revised its rolled steel section standards, inviting us to cooperate. Some work has been done here along those lines and this society, with others, has appointed committees to act in conjunction with the American Engineering Standards Committee. As a result of the war we are in much better shape than formerly as regards the obtaining of a wider range of steel sections suitable for shipbuilding and are not without hope of being in better shape yet, once the revival of business brings the exporters to realize the benefits of standardization.

The British have gone further and are at work standardizing ship fittings as far as found practical and desirable; this is a far-seeing step in the maintenance of their shipbuilding position and one we should not lose sight of.

The work done in the standardization of marine oil engine construction has been fully covered recently in publications devoted to the internal-combustion engine.

Considerable progress has also been made abroad in standardizing steam marine reciprocating engine and Scotch boiler construction as far as moderate and low powers are concerned. This is advantageous in more ways than one. It facilitates construction and, equally important, it facilitates upkeep.

Anything which helps standardization along rational lines should have our united support. The claims for the prompt execution of repairs is one that should not be overlooked it is an aspect of standardization that deserves more attention than it has received, though it is largely taken care of by standardized construction.

Competition and the Future

As an indication of the need that exists for passenger ships, the following table is of interest:

World's Sea-going Tonnage

	1914 Gross tons	1920 Gross tons
Liners and intermediate vessels........	13,345,000	12,107,000
Cargo ships	24,935,000	32,518,000
Tankers	1,479,000	2,934,000
Totals	39,759,000	47,559,000

The lines of tied-up cargo ships are well explained by the above figures. The shortage in ocean passenger ships is brought out, also the wisdom of the Government in deciding to finish the main program of wartime transports later converted to passenger ships. In using the word shortage, care must be exercised to discriminate between present and normal times.

Indications are not lacking that our Pacific and South American trades are soon going to become well developed. On the North Atlantic we are not as yet adequately represented. The Pacific has given one sign of renewed progress in the *Empress of Canada*. She is almost as much a step in advance over Pacific Ocean average as the *Mauretania* was on the Atlantic. Our new liners will not long occupy any leading place among noteworthy ships, so that our hold on the trade will before long demand larger and faster vessels.

The laying down of a 30,000-ton passenger ship by Harland and Wolff for the Holland-America Line is reported, this being the largest vessel commenced in Britain since the war. The end of the retrogression in size appears to be in sight.

Shipping Board Authorizes Sale of Twenty Vessels for Conversion Into Motorships

ADMIRAL W. S. BENSON, commissioner of the United States Shipping Board in charge of construction and machinery efficiency, has announced that the Shipping Board has determined to offer for sale 20 of its vessels to purchasers who will agree under bond, or other satisfactory guarantee, to the installation of full Diesel propelling machinery in such vessels. At present day costs, this installation in a 10,000-ton vessel will amount to around one-half million dollars. Sales of Diesel tonnage have been made abroad as low as $60 but the going rate today is probably nearer $80. The Board is prepared to sell for cash the above tonnage to the highest bidder who guarantees immediate installation of types of machinery to be approved by the Board on such a basis as to make this offer an attractive one.

It is the unanimous opinion of the Shipping Board that in this action it is carrying out three important provisions of the Merchant Marine Act: first, placing of its tonnage in private hands; second, providing the most modern type of vessel for service under the American flag, and, third, giving work to American shipyards at a time when their business is at very low ebb.

Instability

Conditions That May Lead to Instability and the Consequences That May Be Looked For

By C. H. Peabody, Dr. Eng.

IN the design of a ship much attention is given to stability, to ensure that the ship shall have enough and not too much stability in all conditions of service and even though subject to injury. It may be interesting to consider conditions that may lead to instability and what the consequences may be.

Our subject involves a negation and consequently is best approached by considering what is meant by stability and how it is secured.

Fig. 1 gives the ordinary representation of stability; a ship inclined to the angle θ has the center of buoyancy B at which

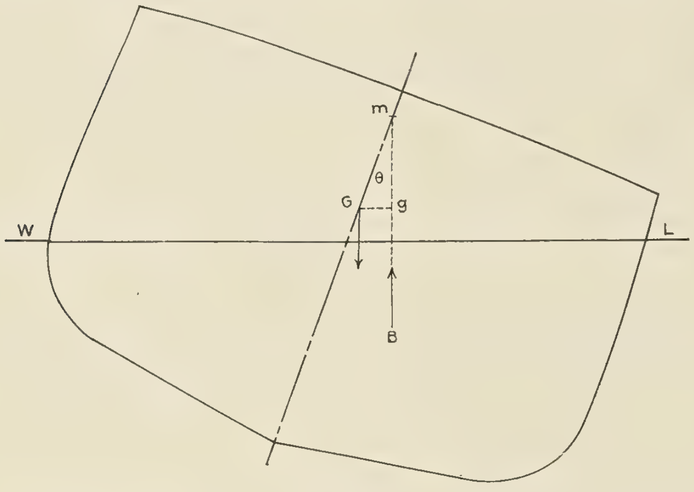


Fig. 1

the buoyant force is applied, the load or weight acting at G, the center of gravity. There is a righting couple

$$D \times G g \tag{1a}$$

when D is the displacement of the ship in tons and Gg is the arm in feet. This expression is known as the stability. By

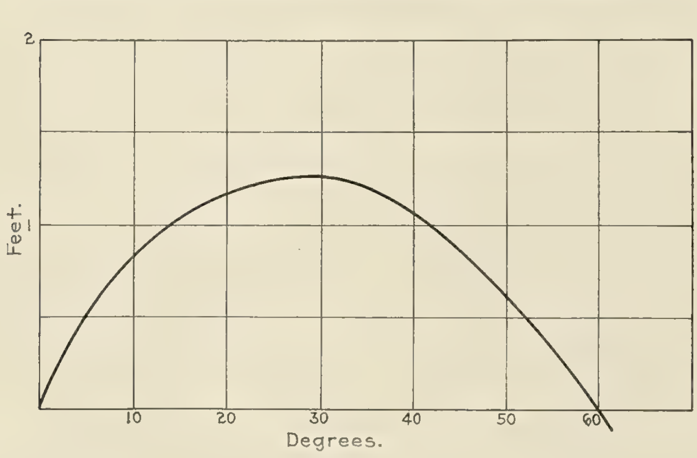

Fig. 2

methods in common use and especially with the aid of integrating instruments the arm Gg may readily be found for any angle and the diagram in Fig. 2 may be drawn which shows the righting arm for all angles up to that at which the stability disappears. The diagram is proper for a steamer which may have a maximum righting arm of 1¼ feet and a range of 60 degrees. A sailing ship will have a higher and longer diagram of stability, the range extending beyond 90 degrees.

Another, and in some ways simpler, method of dealing with stability and conditions leading to instability is by aid of the metacentric height. In Fig. 1 note that the vertical through the center of buoyancy B intersects the medial line through G at the point m; this point varies with the angle of inclination and when that angle diminishes it tends toward a definite point known as the metacenter.

Location of Metacenter

The location of the metacenter is easily determined for a special case as shown in Fig. 3. Suppose we have a floating

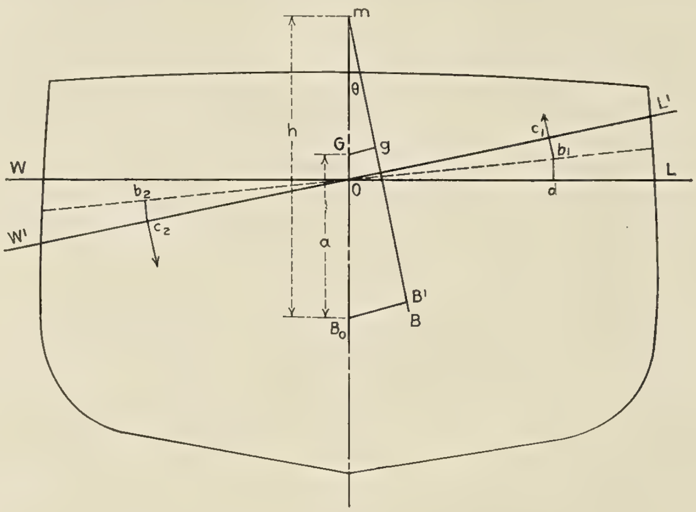

Fig. 3

body (it can hardly be called a ship) that is not only wall sided but is also square ended so that the section shown runs from end to end, or from bow to stern. The immersed volume will be found by multiplying the area below the waterline WL by the length. When the ship is inclined the new waterline $W' L'$ will pass through the midpoint O; a wedge having the area LOL' will be added and a wedge with the area WOW' will be subtracted. The center of buoyancy will go from B_0 to B moving parallel to the waterline the distance BB'.

Now the shift B_0B' is produced by cutting off the wedge WOW' and moving it over to LOL', so that the center b_2 is moved to b_1, that is through the distance c_1c_2. If the volume of the immersed body is V and that of the wedge is v, then

$$V \times B_0B' = v \times c_1c_2$$

$$B_0B' = \frac{v}{V} c_1 c_2 \tag{1}$$

For the crude figure we have chosen for our floating body, or ship, all the quantities on the right hand are easily found. Thus b_1 is on the dotted line bisecting the angle LOL' and at two-thirds of the length of that line from O; but b_1c_1 is drawn perpendicular to OL' and we may draw b_1d perpendicular to OL, whereupon it is easy to see that

$$Oc_1 = Od = \frac{2}{3} OL = \frac{1}{3} B$$

where B is the beam of the ship. Finally

$$c_1c_2 = \frac{2}{3} B.$$

As for the triangular section of the wedge added, its altitude is ½ B tan θ so that its area is

$$\tfrac{1}{2} \times \tfrac{1}{2} B \tan\theta \times \tfrac{1}{2} B = \tfrac{1}{8} B^2 \tan\theta$$

and thus the volume of the wedge is

$$V = \tfrac{1}{8} LB^2 \tan\theta$$

Finally substituting in equation (1) we have

$$B_0B' = 2/3\ B \times \frac{\tfrac{1}{8} LB^2 \tan\theta}{V}$$

$$= \frac{1/12\ LB^3 \tan\theta}{V}$$

$$= \frac{1}{V} I \tan\theta.$$

The letter I is substituted for $1/12\ LB^3$ because it is the moment of inertia of the rectangular waterline of our square ended ship having a length L and a beam B. Any figure has its own moment of inertia which can be computed or

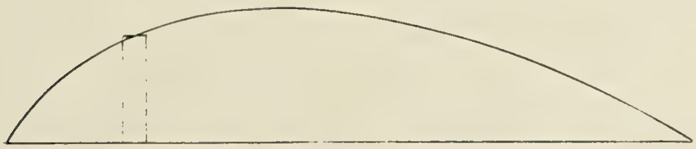

Fig. 4

measured with an integrator. Thus a figure like Fig. 4 may be divided into foot lengths for which the moment of inertia can be computed and then we may sum up for the whole figure.

Like many other things, the moment of inertia sounds worse than it is. It is rather unfortunate as a name because it is long and sounds as though it meant something mysterious. As a matter of fact it means just what it represents, that is

$$I = 1/12\ LB^3$$

for a rectangular figure and something of the same sort for any other figure. We shall later point out its importance for the understanding of stability.

Returning to Fig. 3, let us represent the distance from B_0 to m by h and the distance from G by a. First we may see that

$$B_0B^1 = h \sin\theta = \frac{I}{V} \tan\theta$$

so that

$$h = \frac{I}{V} \frac{1}{\cos\theta} \qquad (2)$$

It is evident that the value of h decreases with the angle θ and that as θ approaches zero h approaches the limit

$$r = \frac{I}{V} \qquad (3)$$

replacing r for h at the limit. This brings us to the consideration of the standard Fig. 5 where B is the center of buoyancy, G is the center of gravity and M is the metacenter; the last name is that given to the limit of the position of m when the ship comes to the erect position.

Returning to equation (1a) and referring at the same time to Fig. 3 we see that the expression for stability may be written

$$D \times Gg = D\ (h - a) \sin\theta$$

For small angles we may replace h by r so that the expression for stability becomes

$$D\ (r - a) \sin\theta \qquad (4)$$

The distance of the metacenter above the center of gravity

$$r - a$$

is known as the metacentric height.

Position of Center of Gravity

This equation gives satisfactory results for angles less than 15 degrees and is a fair approximation to larger angles. Let us repeat that D is the displacement of the ship in tons, r is the distance from the center of buoyancy to the metacenter, and a is the distance from the center of buoyancy to the center of gravity; while θ is the angle of inclination. Of these D and r can be computed with sufficient precision from the lines of the ship, but a which locates the center of gravity is rather difficult to determine in practice.

The location of the center of gravity of a ship depends on the vessel's purpose, construction and loading and is likely to vary widely under different conditions; this is a matter that should be thoroughly discussed by the naval architect and of which the master of the ship should have a good working knowledge. The location of the metacenter can usually be controlled by the naval architect. Consider that

$$r = \frac{I}{V} \qquad (5)$$

and $\qquad I = 1/12\ LB^3;$

by small variations in B, which enters as the cube, the value of r can be given almost any desired value. Again we should have in mind that the metacentric height

$$r - a$$

is likely to vary only from ½ to 4½ feet while r is likely to be from 10 to 40 feet.

Instability, that is the lack of stability, may be a matter of indifference, it may be an annoyance or it may be calamitous; a few examples will be noted.

Steadiness of Ship Not Due to Stability

Contrary to a common idea, stability does not make a ship steady; on the contrary it makes a ship respond readily to

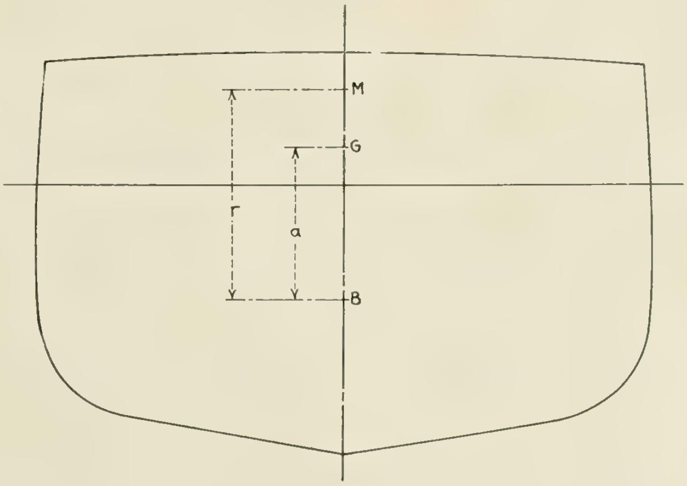

Fig. 5

the influence of the sea so that a stable or stiff ship is likely to roll badly. On high sided passenger ships steadiness is sought by giving a small metacentric height; some passenger ships for the Mediterranean Sea have been given a metacentric height of only six inches. Any ship which is designed for a small metacentric height is liable to lose its initial stability and become unstable. Such a condition will be indicated by a diagram like Fig. 6; when erect, the center of gravity is above the metacenter and the ship is unstable; it will lop over to one side to the angle where the curve crosses the axis, in this case to 10 degrees; if the ship is in a sea-

way it is likely to roll about with a tendency to lean on one side till a wave comes along that throws it over to the other side, and then it will roll about in its new condition. So long as the ship is intact and port holes or other openings are properly closed, nothing untoward will happen. Such a condition is not assuring to the passengers and is not really desirable.

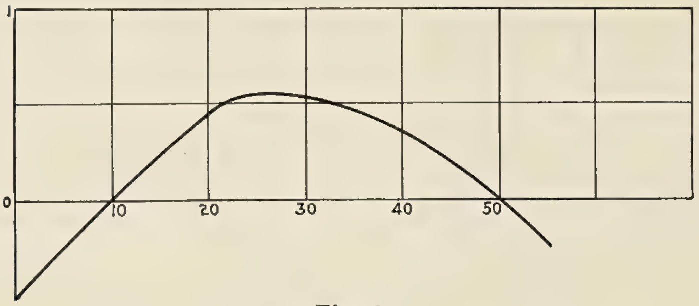

Fig. 6

Effect of Moving or Adding Weights

Before going further let us consider the effect of moving weights aboard a ship or of adding weights. Suppose the weight W_1 in Fig. 7 is raised from the hold to the deck; draw the line W_1G and divide it externally at G_0 so that

$$D - W : W :: GW_1 : GG_0$$

Then from G_0 draw a line to W_2; it will cut the line GM at the new center of gravity G_1; the new metacentric height will be G_1M. Should the new center of gravity rise above the metacenter M, a condition of instability will arise.

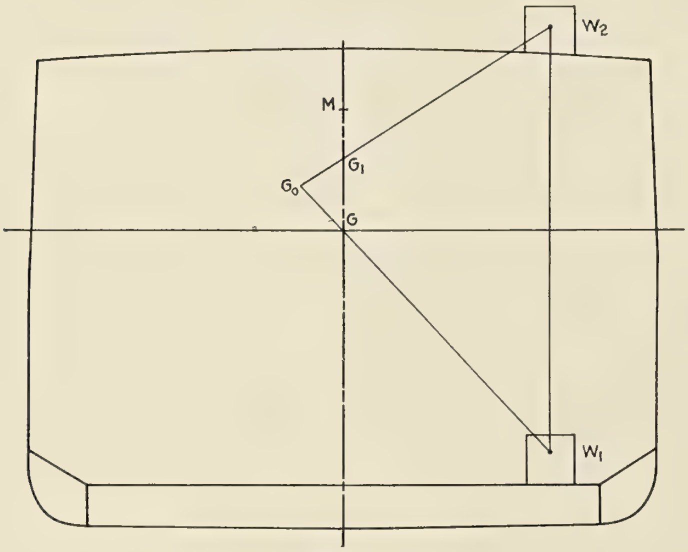

Fig. 7

It is evident at once from the figure that

$$D : W :: W_1 W_2 : GG_1$$

so that

$$GG_1 = (W_1 W_2) \frac{W}{D} \qquad (6)$$

and this equation applies for all conditions, including that with the weight W directly under G. This equation is worked out to get a clear idea of the effect of moving a weight; it may be sufficient to say that the effect is proportional to the weight and to the distance it is moved.

Addition of a weight and its effect on stability is likely to become a bit complicated for this article since it changes the displacement and the location of the metacenter. Clearly the center of buoyancy will rise further above the keel when the displacement increases and the value of r as given by equation (5) will decrease; as these two influences are contrary and as neither is very effective (except for enormous additions of weight), we may usually ignore changes of the metacenter and concentrate our attention to the weight and the location where it is added.

For merchantmen the center of gravity is commonly near the waterline; so there is a general understanding that adding weight above the waterline decreases stability and adding below the waterline increases stability. The first is likely to occur during the outfitting of a steamer or during service, because all sorts of appliances are likely to be placed on the decks; a ship may even become unstable when light from this cause. On the other hand the cargo goes into the hold and the ship may become too stiff if heavy cargo is stowed low.

Removing a weight is merely the contrary of adding a weight. Weight removed from the hold, as during unloading, raises the center of gravity of the ship. This may go on until the ship becomes unstable and then is liable to give a lurch unexpectedly. In the days when steamers carried yards, one, which was unloading at East Boston, thrust her yards down through the roof of the warehouse on the dock. A more distressing accident happened when an express steamer was unloading and coaling at the same time from a lighter alongside, all the side lights were open for ventilation. Suddenly the steamer lurched and taking water through the ports, sank at her berth; and this was in the busy passenger season.

Danger from Grounding of Vessel

When a ship grounds on the keel with a falling tide, there is great danger that she may fall over, because the reaction of the bottom has the same effect as removing a large weight at the keel, and the virtual center of gravity is likely to rise above the metacenter. That this danger is not suppositious is indicated by the fact that ships sometimes fall over in the dock, most frequently when undocking. A certain royal naval constructor was most unjustly blamed for such an accident to a royal yacht. As another example we may quote the well known danger of grounding a small boat on the beach, even in fair weather unless men are told off to go overboard and hold the boat. Many an amateur canoeist has learned this danger to his discomfort if not to the peril of others.

One of the most fertile causes of instability is the presence of loose water in a ship or boat. To make this matter clear we may direct attention first to the fact that a suspended weight is applied at the point of suspension; the moment a weight is free from the deck it is applied at the head of the boom and has its full effect on raising the center of gravity of the ship. Now water contained in a receptacle is the inverse of a floating body and has much the same properties. In Fig. 8 the water in a tank has its mobile center of figure at B and directly over is the metacenter to be located by aid of equation (5). The water in fact acts as though it were suspended from the metacenter M and must be assumed to act at that point when considering its effect on the virtual center of gravity of the ship. Of course when a closed receptable is once full of water it acts like a solid and its weight is applied where it is.

Effect of Loose Water in a Ship

A curious and frequently distressing feature of loose water is that a small amount has a high metacenter. This comes from the fact that the distance MB is

$$r = \frac{I}{V}$$

which becomes very large when V is small. We have in mind that

$$I = 1/12\ B^3L$$

from which it is evident that one way of curbing the rise of the virtual center of gravity is to reduce the beam B of the tank. This is one of the reasons for putting in midline bulkheads, which evidently makes B half as much and therefore greatly reduces the moment of inertia. A notable instance of the reduction of beam of free fluid is the form of expansion trunks of oil steamers; they are placed amidships and are very narrow so that the mobility of the oil has little effect.

During the loading or unloading of an oil tanker the compartments (or some of them) are partially filled and instability is likely to occur. The designer of the ship must make due provision to ensure that there shall not be any danger of capsizing; very commonly a tanker takes a list when unloading that may amount to 15 degrees, but if the designer has taken this into account the crew take that as a matter of course.

A very perplexing condition may arise if a ship, when light, loses stability due to burning of coal. If the ship has

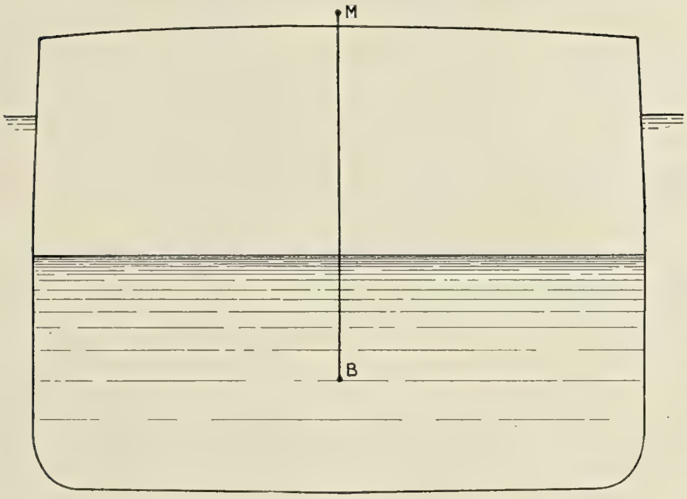

Fig. 8

water ballast tanks, the natural remedy would be to run in water; but in such case the captain must bear in mind that the first effect is to diminish the stability. But if all side openings are closed and if one compartment is dealt with at a time, there may be no occasion for alarm even though the ship should take a small list.

A very simple experiment will show some of the effects of flooding compartments. Take a common biscuit tin and set it afloat in a pan of water; the box will leak at a convenient rate. Since the metacentric height of a shallow layer of water is great, the box immediately becomes unstable and takes a list that increases more and more; but after a while the limit is reached after which the box rights and finally goes down upright.

A Mishap That Might Have Happened

Accidents that don't happen attract little attention; usually some one is blamed for being a busybody; but the old adage holds that it is better to be safe than sorry. One of the numerous pageants of recent years had as a prominent feature a magnificent barge 80 feet long and 20 feet wide all plastered over with stucco work and with a high deck to properly stage the participants. Now the designer of the barge knew it had immense initial stability and did not want interference by carping critics, so details were kept in the architects' office—not a naval but an ordinary architect. But some of the probable passengers became concerned at the policy of secrecy and the plans were submitted for official inspection.

The barge had a gasoline engine but also for proper appearance had a crew of oarsmen under the deck; the freeboard to the oar holes was of course trivial. Two cautions were impressed on the director of the pageant: (1) Keep the hold dry (this to avoid the cracker box effect) and (2) Keep the passengers from rushing over to the rail. These rules, rigorously enforced, cut out all chance of a disaster. But the architect, or somebody else, thought that more stability would help and put in a lot of sand ballast which was of course worse that futile because it lessened the freeboard and would have no effect whatever on mobility of water that might leak in. As previously stated, however, nothing happened until after the spectacle, when the barge drifted from her moorings and was wrecked on a mud flat. But computations showed that an inch of water in the hold or a rush of the passengers to the rail would submerge the oar holes after which anything could happen.

Let us contrast this commonplace affair with the capsizing of the *Eastland* in the Chicago river while taking on passengers for an excursion; a disaster that had its grewsome tale of loss of life. The published account of the investigation was inconclusive, but it is pretty certain that some water ballast tanks were partly filled and there is some question whether or not she touched bottom. A crowd of passengers at one rail was a condition evident to everyone.

The Seaworthiness of Small Boats

The writer had at one time an honorary connection with the life saving service and acquired a great interest and some trivial knowledge of small boats, not to mention his experience with canoes and skiffs. Now a good ship's boat in the hands of an able seaman is in reality a little ship competent to make long sea voyages. An acquaintance of the writer, a competent sea man, considers a voyage of 1,200 miles in such a boat as all in the day's work. That is what can be done with a well found boat. That is the kind of boats carried by ships in former years and familiar to passengers as occupying good deck room. Then came the wreck of the *Titanic* with its fearful loss of life. Legislators could easily order boats enough on every ship to accommodate all aboard; and to conform to the letter of the law the shipping companies took on board various forms of collapsible boats. Now a plain collapsible boat is evidently a poor substitute for a real boat; and yet when set up and put overboard it has saved life; it did on the doomed *Titanic*.

But the ordinary collapsible boat met the approval neither of the authorities nor of the traveling public and a variety of semi-collapsible boats was put on the market, accepted by the authorities and put aboard steamers. The lower half was built of wood or metal and provided displacement to carry the load; the upper or canvas half, when drawn up, made the craft look more like a boat and at least could keep off wind and spray. Like all compromises they were more or less unsatisfactory; when in good condition and in still water they might be useful but in service conditions any of them might be a delusion if not a snare. But they filled the letter of the law—an unreasonable law, incapable of fulfillment. The worst of them had a pontoon body and were so flat and shallow that they were more or less like a raft with the virtues and defects of a raft.

At first sight such a boat may appear more stable than a standard lifeboat; at least the empty boat had a greater metacentric height; but the passengers were carried on the deck and had a high center of gravity. Any water on the deck would have its usual tendency to instability with the further ing toward instability; the pontoon was liable to leak after exposure on the ship's deck and loose water in the pontoon would have its usual tendency to instability with the further condition that it could not be bailed out. Fortunately most of these substitutes for real boats are now discredited and retired from service.

Reference was made a moment ago to the virtues and de-

fects of rafts. Now a raft has a large area and small draft so that its moment of inertia and metacentric height are very large; in smooth water it is very stable. It faithfully follows the surface of large swells in a seaway, but smaller waves come aboard and reduce the stability on account of reduction of the moment of inertia. A raft is liable to dip one edge, slide sideways, drop its load and then ride the waves securely.

Water in an open boat rapidly cuts down the stability. That is the real reason for bailing frantically when waves break in; should the boat be swamped, it is likely to capsize and spill all its passengers. The pressing danger is instability and an overloaded boat is in the greater danger from that cause.

The old-fashioned sailing and rowing lifeboat is passing out of service being replaced by power boats. The first power lifeboats developed in Great Britain were hydraulically propelled steamboats; the absence of external propellers enabled them to venture onto sand bars and into floating wreckage. They were like small, low tugboats, beamy and decked over. Their crews gained great confidence in them and eventually one was capsized and lost on account of over confidence; that is what happens when bold men go into danger to help others. The American boats have gasoline engines and their propellers are in cages or else in tunnels. They were developed from the old sailing and rowing boats and are handy, capable craft.

The typical lifeboat, developed in Great Britain and extensively used on our Great Lakes, was a powerful whale boat with a deck, high ends and a heavy metal keel. The deck above the waterline prevented foundering, and the combination of high closed ends and a heavy keel made the boat self-righting. These boats had a deservedly high reputation and the crews had an enthusiastic confidence in them. They were so big and heavy that they were habitually launched from fixed ways at the harbor mouth. Frequently they were towed to the windward of a wreck; after the rescue they were sailed and rowed to some haven of safety. These boats had a high reputation for stability; as a matter of fact the stability was purposely limited to secure self-righting when capsized. When capsized they were logy in still water but rolling around among waves they quickly righted. They carried gear, crew and passengers on a deck above the waterline and required skillful handling when so loaded. They were great boats and had their crews' absolute confidence.

It is related that one of these lifeboats when towed at speed by a revenue cutter to a wreck, capsized three times and each time righted without losing her crew.

Electric Propulsion of Ships*

Diesel-Electric Propulsion—Reliability—Weight—Economy—Control—Electric Drive on Warships

By W. E. Thau†

FOR practical reasons, direct current only is feasible with Diesel-electric drive. This will be evident by a proper analysis of the performance of Diesel engines in connection with the characteristics involved in applying alternating current and direct current machinery, due consideration of ship requirements being taken into account. To obtain the best results with Diesel-electric drive, it is necessary to provide several relatively small and moderately high-speed generating sets for supplying power to single or doube-unit direct connected propelling motors. Not only must the generated power divide evenly or proportionately between the generating units, but the system must also be such as will conveniently and economically lend itself to speed control to meet the requirements of service.

In the case of alternating current, it would be necessary to operate the generators in parallel. To operate alternating current generators in parallel necessitates the very closest speed regulation and practically identical angular velocities of all prime movers. To visualize properly this exacting requirement, it must be remembered that satisfactory parallel operation of alternating current generators necessitates that the angular displacement of the field poles of one machine with respect to another must not vary more than approximately ± 3 electrical degrees, or a total of 6 electrical degrees. Since 360 electrical degrees constitute the space between adjacent like poles, the total variation in mechanical degrees, for example, in the case of a 20-pole machine, must not exceed 0.6 degree. While successful operation under such requirements is carried out in several land installations where the prime movers operate at constant speed, it is not considered safe practice on board ship *where the necessity for varying the speed of all sets simultaneously* introduces another very serious difficulty. To overcome this condition successfully, would require absolutely perfect engine governors which would function 100 percent perfect at any speed setting. The speed of the motor could be varied by the rheostatic method, thus allowing the engines to operate at constant speed; however, this method is extremely wasteful at reduced speed operation, and at best offers a solution for only one of the many difficulties. It is for these reasons that alternating current is not suitable for Diesel-electric propulsion.

Direct current not only obviates all of the above difficulties, but possesses many advantages in the way of operation, control and reserve power. With direct current, we have the choice between two methods of generator operation, *i. e.,* parallel and series. From the standpoint of engine performance only, parallel operation of direct current generators is entirely feasible and easily accomplished. However, when considering economical methods of speed control of the propeller motors, another factor enters which makes parallel operation difficult, even with direct current machines. This is explained below.

With direct current, we have a choice between two methods of motor speed control, *i. e.,* armature rheostatic and generator voltage control. Armature control is not only unjustifiably wasteful at reduced speed operation, but also adds complication to the control. On the other hand, the voltage control method is practically 100 percent economical and provides an ease and a flexibility of control unapproachable by other systems. In the case of very small drives, armature rheostatic control might be selected because of factors not related to the propulsive equipment making it preferable to have a constant voltage system which is common to the propulsion and auxiliary circuits. For a drive of any appreciable size, the best results are obtained by isolating the propulsive equipment so that immediate maneuvering can be done without affecting non-related circuits. Therefore, hav-

*Concluded from December, 1921, issue.

†Marine department, Westinghouse Electric and Manufacturing Company.

ing an isolated plant for propulsion only, voltage control is obviously the method to use.

With parallel operation of generators, voltage control is not simple of accomplishment. To vary satisfactorily the voltage of two or more generators simultaneously over the full range from zero to maximum, necessitates very closely and very carefully adjusted field rheostats, generators with practically identical saturation curves, and engines with practically identical regulation; or, some complicated and delicate automatic voltage balancing instrument.

The series arrangement of generators, however, is ideal from every standpoint such as operation, control, economy, simplicity, flexibility, reserve, etc. The series arrangement, in eliminating parallel operation of generators, obviates the necessity for close regulation and hence simple engine governors and simple field rheostats are entirely satisfactory. In other words, satisfactory operation is independent of variation in voltage between the different generators.

Besides the operating advantages, the series arrangement inherently provides for full power from each of the remaining generators in case of casualty to one or more of the generating sets without providing additional capacity, and consequently additional weight in the motor. To obtain full power from each of the remaining sets with parallel operation would necessitate increasing the motor field in order to lower its speed to such a value as would require the total capacity of the remaining units, thus necessitating a larger and heavier motor.

Fig. 5 shows a diagrammatic scheme of connections for a single screw Diesel-electric drive. In this particular case, there are six generating sets and one double unit direct connected motor. The six generators and the two motor units are connected in series. The machines are distributed electrically as follows: three generators, one motor unit, three generators and one motor unit, to reduce the voltage strain, or the maximum voltage to ground at any two points to one-half the total voltage of the system. The voltage of each generator being 250, we have in effect a 1500-volt system with only 750-volt insulation requirements. The advantages of this arrangement are obvious, especially in the case of large capacity drives and where there are several generators involved. The diagram shows an arrangement for using as many as may be desired of the main generating sets for supplying power to the ship's auxiliaries when in port. Although the generators (and motors) operate as pure shunt machines when driving the ship, series windings on the generators are automatically placed in circuit when the generators are connected to the auxiliary bus, and therefore, the generators operate as compound machines when supplying the auxiliary load, and when used for this purpose the generators are operated in parallel. Arranging the generators for supplying power to the ship's auxiliary bus determines the voltage of the individual machines (250 volts).

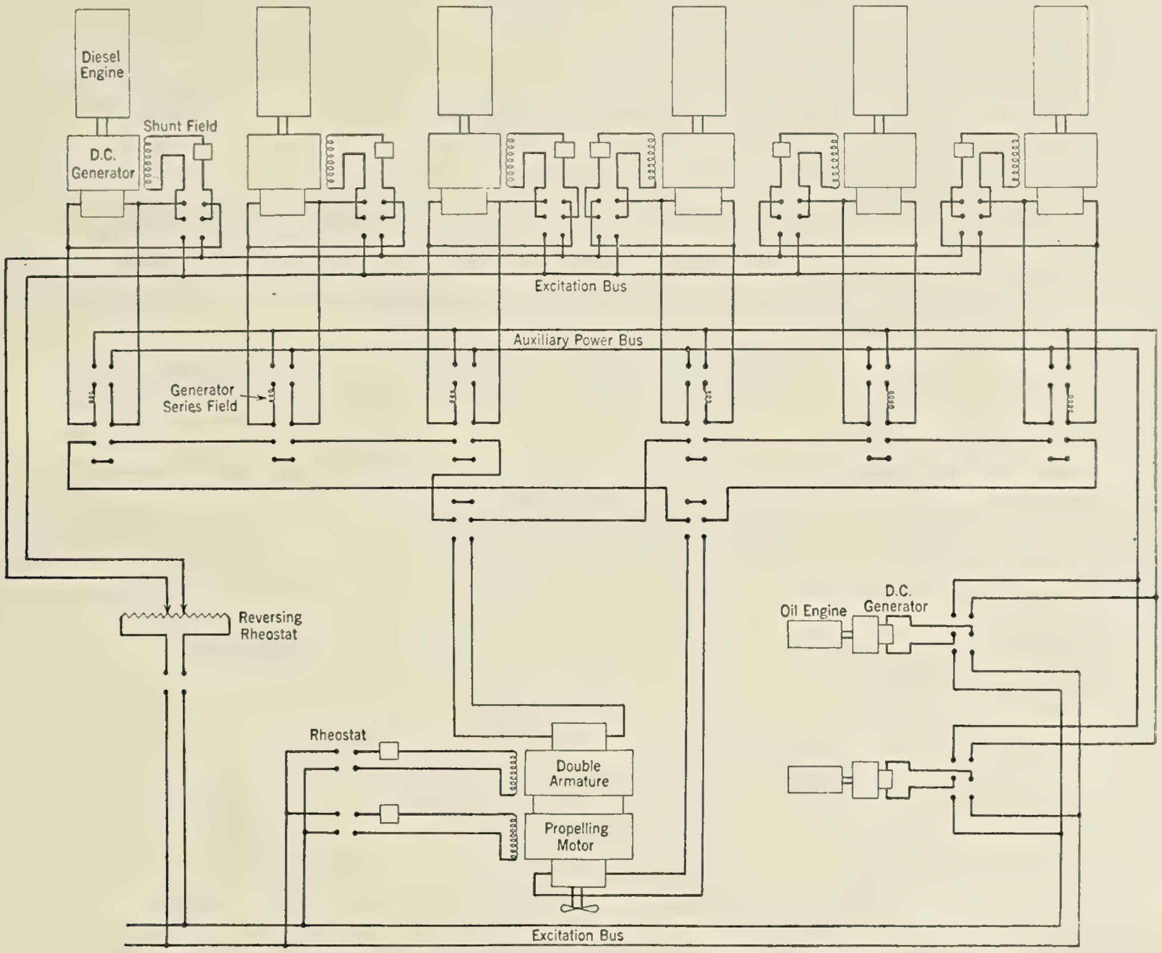

Fig. 5.—Diagrammatic Scheme of Connections for Diesel Electric Drive

The motors and generators being pure shunt-wound machines, the motor speed is adjusted to any value within the requirements by the voltage control system. In this system, the generator and motor fields are separately excited (preferably from the same excitation source). The motor fields are excited at constant potential, and in one direction, whereas the generator field excitation is varied to obtain the motor speed desired. With this arrangement, the speed of the motors is directly proportional to the generator voltage and, therefore, any motor speed from zero to the maximum in either direction is obtained by merely manipulating the generator field rheostat (a common rheostat is used for all generators). Since the rheostat handles only the generator

field current which is 1 percent to 1½ percent of the generator rating, the simplicity and economy of the control is obvious. With the type of rheostat used, the excitation of the generators may be varied from full excitation in one direction to full excitation in the opposite direction, without opening the field circuit, and therefore, the ship can be brought from full speed ahead to full speed astern without opening a single circuit.

Reserve power in the event of casualty to prime movers is greater with this type of drive than with any other. On the basis of the power varying as the cube of the speed, a three-engine unit Diesel-electric ship can make 88 percent speed with two generators and 70 percent speed with only one generator.

The Diesel-electric has the greatest range of application of any of the economical drives (geared turbine and turbine-electric not excepted). Because of the inherent merits of this drive, it is very suitably applied to merchant ships, barges, river boats, lake boats, ferry boats, small coastwise vessels, yachts, fishing boats, coast guard cutters, cable laying ships, and any ship within its capacity requiring refined control and economical operation over a wide range of speed.

As compared with any type of steam drive, the principal advantages of the Diesel-electric are:

Fuel consumption,
Weight,
Control,
Considerably more reserve power in case of casualty to prime movers.

The principal advantages of the Diesel-electric drive as compared with direct Diesel drive are:

Reliability. Cylinder parts being thinner are not subjected to such high temperature strains in heads and liners as are the large low speed engines, and consequently, there will be fewer breakages of these parts. Years of application and service demonstrate beyond a doubt the full reliability of electrical machinery.

Maneuvering Ability and Control. The control is extremely simple, easily understood, and can be placed anywhere on the ship. The engines run at constant speed and hence the engine reversing gear is eliminated.

Weight. On a very conservative basis, the Diesel-electric should show at least 100 pounds less per propeller shaft horsepower.

Propeller Application. Propeller speed not restricted, and in the case of large ships, one propeller would be used for Diesel-electric, whereas, because of engine conditions, two would be used with direct Diesel.

Reserve Power in Case of Casualty. Very much greater with the Diesel-electric.

Maintenance. For reasons under "Reliability," the maintenance should be less. Furthermore, due to smaller parts and reserve power, repairs to Diesel-electric engines can usually be made on board ship while under way, providing sea conditions permit. The engines for Diesel-electric are designed and built on the same conservative basis as direct drive Diesels, and are not the high speed, short lived submarine type.

Less Starting Air. Diesel-electric requires starting air only during the initial start in port. Subsequent engines may be started electrically. No air is used during reversing and consequently, the air problem is reduced to simplest terms.

Fuel Consumption. There would be little difference in the net fuel oil and lubricating oil consumption as the increased efficiency of screw and the reduced strut losses, with the low speed single propeller Diesel-electric, offset the twin screw arrangement of the direct Diesel. From a standpoint of piston speed, the engines used for Diesel-electric drive are no different than direct-connected engines. (The former exceeds the latter only in *revolutions per minute.*)

Cost. The cost of Diesel-electric in some cases is less than the cost of direct connected Diesel drive on present day figures, and will generally show a greater gap when fully developed along standardized lines.

General Summary for Merchant Ship Electric Drives

In the way of a summary relative to all types of electric propulsive equipments for merchant ships, the following salient features may be reviewed:

1. Electric drive is as reliable as any drive suitable for ship propulsion.
2. Maintenance and repairs should not exceed those of other drives, and in some cases should show a saving.
3. Electric drive is ideal for ship propulsion, and will soon be recognized (if it is not already recognized), as a standard type along with the reciprocating engine, geared turbine and Diesel engine drives.
4. Electrical machines have longer life than engines or geared turbines (drives) and do not decrease in efficiency with age.
5. Electric drive (Diesel-electric) is as reliable as any economical drive generally; weighs less than any other drive; is as economical as the best; in most cases costs less than any other drive;* provides more reserve power in case of casualty to prime movers; and affords simplest and most flexible control.

War Vessels

The electric propulsive equipments for war vessels have been described and discussed in many articles in the technical press, and therefore, only the principal phases will be dealt with here.

The fact that the last nineteen capital ships of the United States Navy are, or will be equipped with electric drive, is sufficient testimony in behalf of what the builders and users of war vessels think of its merits. The prime requisite of reliability in any type of machinery designed to propel war vessels was recognized in the electrical machinery at the time of the first installation. Also the calculations showed that the unit fuel consumption over a wide range of operating speeds should be better than anything yet proposed. Service operation of two 30,000-horsepower electrically propelled battleships has indisputably proved that the reliability is all that was claimed, and that the fuel economy as compared with other ships of the same type using direct connected turbines with geared cruising turbines, is vastly superior.

Two other factors in which the electric drive shows a marked improvement over other drives, have been emphasized since the first battleship was built, namely, the superior protection from torpedo attack afforded the machinery by virtue of the arrangement of the electric plant, and the superior maneuvering qualities of the electric drive. The large horsepower requirements of the present war vessels (60,000 horsepower and 180,000 horsepower) preclude the use of reciprocating engine drive, and this leaves electric drive with a decided maneuvering advantage over any other form of turbine drive.

Of the two types of electric propulsive equipments, only the turbine-electric is suitable for propelling war vessels, because of the large capacities required. The nineteen drives installed and building employ essentially the same system in that induction motors are used in all cases. In details, the systems differ in regard to the type of induction motor. Of the three ships in service (the *Maryland* having been recently commissioned), the *New Mexico* motors have the double squirrel-cage rotor winding, the *Tennessee* motors have the form-wound rotor with external starting and maneuvering resistance, and the *Maryland* motors have combined single squirrel-cage and form-wound rotors. Each of these

*It is predicted that future developments will bring the item of cost below that of any other drive.

ELECTRICALLY PROPELLED WAR VESSELS IN SERVICE AND BUILDING

arrangements has its advocates. However, continued service alone will decide which method is the most suitable, all factors being considered.

Because of limitations in weight and space factors, electric drive is not well suited to small, high power, fast craft such as destroyers and scout cruisers. In the case of ships where conditions are suitable for electric drive, the following discussion of the more important factors will be of interest:

Reliability

In all phases of the industrial field where electricity has entered, it has proved its reliability. With a good record for reliability behind it, electricity has set out to establish a similar record on the sea, and the experience of the two large battleships thus far equipped with electric propelling machinery, and in service, shows that there will be a duplication of past satisfactory performance. The electrical machinery will be found to be in good condition long after the ship has become obsolete.

The arrangement of units and distribution of power make it possible to supply balanced power to all screws in the event of casualty to one of the prime movers. In other words, the electric drive possesses an inherent advantage in regard to reserve power.

Economy

Regardless of calculations, the recorded performance of the electrically propelled battleship *New Mexico* has proved the superiority of the electric battleship in respect to fuel consumption. Recently published figures show that the *Idaho* and *Mississippi* use 20 percent more oil at 10 knots than the *New Mexico;* 42.7 percent more at 13 knots, 48 percent more at 16 knots, 40.1 percent more at 19 knots, and 32 percent more at full power. This superiority in fuel consumption is not altogether due to the main units, as the figures include the oil consumed by the auxiliaries. There is enough difference, however, to show conclusively that the comparison is very favorable to the electric ship.

To show that the advantage in fuel consumption demonstrated by the *New Mexico* is not a mere incident, it is well to note that the *Tennessee,* which is a later ship, is showing even better results than the *New Mexico,* as was indicated when the two ships steamed together during recent maneuvers of the Pacific Fleet. Accurate measurement of unit fuel consumption during the official trials of the *Tennessee* showed that the actual steam consumptions were less than the guaranteed figures by amounts varying from 3 percent to 8 percent approximately. Thus the art of electric propulsion is still progressing. The answer is found in the use of only a sufficient number of turbines for the load conditions, and in the two speed motors, the combination of which maintains a higher average load on the turbines at a higher average speed.

Maneuvering

Owing to the availability of full backing power in the case of the electric drive ship, the latter possesses a marked advantage over the turbine ship in maneuvering qualities. As these were referred to under "Merchant Ships," it is sufficient merely to mention at this time that electric battleships can be stopped in considerably less time than is required to stop a turbine ship. The advantage of this feature is obvious in the case of a war vessel. This is due to the combined action of quicker "set-ups" and greater backing power.

Further maneuvering advantages of the electric drive are apparent from recent publications. These advantages are chiefly concerned when entering and leaving ports and maneuvering therein. By operating the ship from one turbine set, the other, or others if there are more than two, can be held in readiness for immediate service in case of necessity such as would arise from a mudded condenser or other cause. When maneuvering to get under way, operation from a single generating set inherently enables exactly the same speed—but of opposite direction—to be obtained on the port and starboard screws. This is very desirable for the reason that the ship can be turned on its heel without making any headway. With different prime movers supplying power to

the various screws, it would be difficult to maintain all the screws at the same speed and thereby turn in the same space.

Control

The control for the propelling machinery is centralized in one compartment and can be easily arranged to be operated by one operator. The flexibility of the control is such that almost any emergency resulting from casualty to any equipment connected with the propulsive machinery proper, can be taken care of in brief time by disconnecting the disabled unit from the source of power.

Maintenance

The maintenance and repairs should show to advantage because of the inherent reliability of electrical machines and the absence of wearing parts. Repairs of considerable magnitude can be made aboard the ship without removing the machinery. It is difficult to imagine a casualty to any one of the electrical units which could not be repaired on board the ship if circumstances warranted it.

Study of Performance

The electrical instruments enable accurate and convenient observations to be made of the performance of the screws at any instant. The electrical instruments also provide a means for quickly detecting improper performance of the screws due to excessive shaft friction or damaged blades. The performance of all units as indicated by the instruments is under the observation of the watch officer and control-room attendants at all times.

Memorial Tablets for Captain Ericsson

MARCH 9, 1922, will be the sixtieth anniversary of the battle of the *Monitor* and *Merrimac* at Hampton Roads, Va., which demonstrated the merits of the turreted battleship. That has been the date selected by the DeLamater Ericsson Tablet Committee of the American Society of Mechanical Engineers to memorialize the services of Mr. Cornelius H. DeLamater and Capt. John Ericsson, who for 50 years, 1839-1889, were pioneers in developing the naval, marine and industrial interests of this country, and who at the time of the Civil War, without thought of personal reward, turned their mental and financial resources to account and applied their knowledge and experience to accomplish what the Government had failed to do.

The Government has appropriated $35,000, and private individuals have subscribed a larger sum for a memorial to Captain Ericsson, in Washington adjacent to the Lincoln Memorial, and $5,000 is being raised by private subscription among engineering and marine interests to erect bronze tablets on four sites of buildings in New York City with which the lives and work of the two men were identified.

These are (1) the Phoenix Foundry, 260 West Street, between Laight and Vestry Streets, where the first iron boats in this country were built and the screw propeller was first introduced on river and ocean steamers. Some of the equipment of the *Princeton,* the first battleship with machinery and boilers below the water line safe from cannon shot, was constructed there, revolutionizing the navies of the world. The 3-inch pipe for the Croton Aqueduct and hot-air engines to pump the Croton water to the upper floors of houses were conceived and built there, as well as much other notable work. (2) The DeLamater Iron Works, foot of West 13th Street, where many industries now internationally established obtained their first development. There the first self-propelled torpedo, the first torpedo boat, the first submarine boat, and the engines for the original *Monitor,* were built, and the *Dictator* was built complete. (3) The Continental Iron Works, Greenpoint, Brooklyn, L. I., where the hull of the original *Monitor* was built and the *Puritan* and other monitors were built complete; and (4) No. 36 Beach Street, where Captain Ericsson lived and worked and died. By the *Monitor,* the navies of the world were revolutionized a second time.

The DeLamater Ericsson Tablet Committee announces that it has had a communication from the Board of Directors of the Association of Swedish Engineers (Svenska Teknologforeningen), Stockholm, Sweden, stating that they will hold a celebration of the sixtieth anniversary of the battle of the *Monitor* and *Merrimac* simultaneously with the celebration which the committee will hold in New York and Washington on March 9, 1922, as announced in the September issue of *Mechanical Engineering.* It is expected that members of the Royal Family and the American minister to Sweden will be present at the Swedish memorial meeting.

Portable Taper Boring Bar Has Wide Application in Marine Field

FOR such work as reboring propellers or other machine work where a tapered hold is required a portable taper boring bar has been developed by the Pedrick Tool & Machine Company, Philadelphia. So far as known, this is the first portable bar having the feature of adjustment for any required degree of taper.

Its operation is the same as that of the regular cylinder boring bar developed by the company in that the piece being

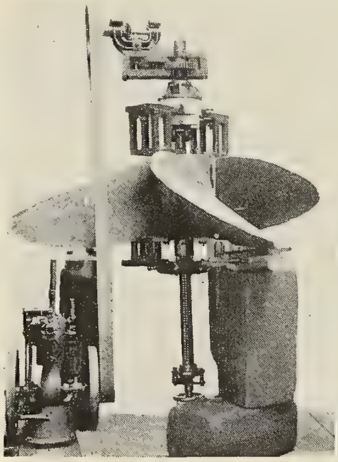

Fig. 1

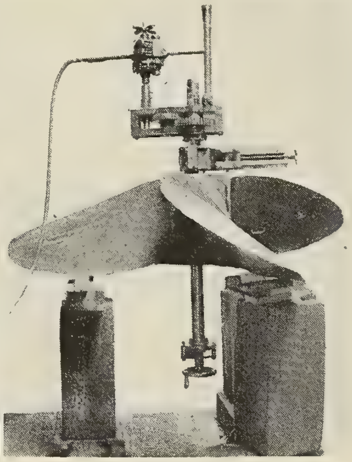

Fig. 2

bored serves as a support for the machine (Fig. 1). To this piece are fastened the crossheads that hold the boring bar. These crossheads have four set screws arranged radially for the final alinement of the bar after it has first been roughly centered in the hole to be bored. The conical motion of the bar which gives the hole the proper taper is derived from a cross slide and yoke in which the bar is secured by a gudgeon pin. The degree of taper is controlled by the distance the slide is moved from its central axis. The lower end of the bar to which the feed case is attached describes a circle. By preventing the hand wheel of the feed case from turning, either by means of a weight or some other simple method, the feed becomes constant and automatic.

The driving gear is stationary so that it may be belt driven or by an air drill or electric motor in either the vertical or horizontal positions.

In Fig. 2 the facing arm attached to the device is shown machining the hub of the propeller. This operation requires the removal of the crossheads and space blocks used in the boring operation and the attachment of a different device for holding the bar. This device consists of "spiders" which are held in the bore of the hub both on the top and bottom by projecting set screws.

Calking Materials for Shipbuilding Purposes

By Horace Holden Thayer*

Continuation of a series of articles containing information regarding shipbuilding materials and their uses that is not readily obtainable from shipbuilding handbooks and other generally available sources. The articles are not intended to be a complete exposition of the subject but will be found to contain items of value to the various classes of workers in this field who have to deal with these materials from the materials point of view.

THE principal calking materials dealt with in this article are those required to make the seams between strakes of planking or wood decking watertight. The calking of steel is a metal to metal operation; and such packing as is occasionally required on steel ships, and the red lead putty or tallow mixtures used in stopping up otherwise inaccessible crevices on both steel and wood ships call for but brief mention.

In the calking of a wood hull or deck the seam is first nearly filled with calking cotton or oakum, or both, as the main calking materials and these are then protected by a covering of seam composition, marine glue, pitch or cement. Wood calking wedges are sometimes used for the inside ceiling of wood vessels and for floating dry docks and other special work. These different materials will now be considered.

Oakum

Oakum is a mass of strong pliable vegetable fibers which have the property of swelling when wet and are therefore called soft fibers. The fibers are impregnated with pine tar and are loosely bundled together. Before oakum is used it is worked or "spun" into "threads" which run from 40 to 75 feet in length to the pound; this spinning is done either by the manufacturer or at the shipyard. The fibers must not be too springy and on the other hand they must not be so soft as to calk into a hard wedge without elasticity.

The best fibers for marine oakum are Russian hemp; Italian hemp is next best. Sunn, sometimes called Sunn hemp, is an East Indian plant with fibers of the proper strength, absorbent qualities and resistance to decay to make good oakum but somewhat inferior to Russian and Italian hemp; Benaries is another Indian plant of the same nature.

American hemp fibers are somewhat too soft and inferior in elasticity and an oakum made entirely of them will pack solid and give poor service. Flax fibers are good but being usually more expensive than and not as good as hemp are naturally not much used.

Jute, which is the fiber from either of two other East Indian plants, does not make satisfactory oakum for shipbuilding purposes as it is more woody and weaker in tensile strength than the fibers before mentioned and is subject to rapid decay from moisture.

Oakum is often adulterated by the use of hard fibers such as Yucatan henequen, Java sisal, New Zealand flax and the ixtles, which do not swell when wet; but these can be readily detected. Not only are they not suitable in this respect but they are springy and cannot be properly wedged into the seams. Their use should therefore be absolutely prohibited.

The fibers for oakum may be new or obtained from cutting up old tarred hemp rope into short lengths and pulling the fibers apart. The oakum made from new fibers is preferable, being free from the knots or unravelled yarns which are unavoidable with oakum made from old rope.

In the spring of 1918 on account of the large amount of oakum required for the wood ships of the United States Shipping Board Emergency Fleet Corporation, the Bureau of Plant Industry of the United States Department of Agriculture and the Bureau of Standards of the Department of Commerce made an extensive study of oakum fibers. Later in the year specifications for several grades of oakum were prepared and presented to a conference at the Bureau of Standards attended by the Government bodies interested and the oakum manufacturers. The provisions of the specifications as approved by those present show clearly the relative value of the different fibers and give other information necessary for a proper selection of the material for shipbuilding purposes. They were in substance as follows:

(a) The grade known as No. 1 grade oakum shall be made from Italian, Russian or American hemp (Cannabis sativa), line or tow, or from any No. 1 grade Sunn, or No. 2 grade Benaries, or North Bengal Sunn, or from any combination of these fibers.

(b) The grade known as No. 2 grade shall conform to all the requirements of No. 1 grade except that flax fiber may be used in quantities not to exceed 25 percent of the total weight of the fibers.

(c) The grade known as No. 3 grade shall conform to all the requirements of No. 2 grade except that jute may be used in quantities not to exceed 25 percent of the total weight of the fibers.

(d) The fibers shall be thoroughly impregnated with pine tar to an amount not to exceed 30 percent of the total weight of the fiber and tar.

(e) Hemp (Cannabis sativa) recovered from old rope shall be considered the same as new hemp of the same grade and name.

(f) Where percentage of any fiber is stated it shall be understood that it is percentage of the original weight of fiber before impregnation. The original weight of the fibers shall be determined under ordinary atmospheric conditions.

(g) All oakum shall be thoroughly carded and finished, free from excessive lumps, dirt or other extraneous matter.

An explanation of the foregoing expression, "line or tow," is that the Bureau of Standards defines tow hemp as hemp obtained from the combing out process from the line hemp. Some of this tow is very short stuff that becomes waste when the oakum is spun; the more of this there is, the poorer the oakum. An oakum manufacturer on the lookout for good material can often obtain cargoes or part cargoes of hemp that have been imported for weaving and been somewhat damaged in transit at figures low enough to enable its use in oakum, with a resultant increase in the length of the fibers and the quality of the oakum produced.

The Navy Department specifications for oakum dated March 1, 1919, exactly follow provision (a), without reference to grading, and also provisions (d), (e) and (g) and retain the original Navy provisions for machine spun oakum and for delivery in bales of about 50 pounds each, compressed no more than necessary and securely bound with laths and strong tarred sisal yarns. The provision with regard to spinning is as follows:

> Oakum shall be spun by machine into slivers or threads in the form of balls or hanks not exceeding 5 pounds each; it shall be soft and uniform in texture, strong and sufficiently twisted to be suitable in all respects for calking seams of vessels. The slivers or threads shall contain not less than 43 feet to the pound and not more than 75 feet to the pound, unless otherwise required.

*Member of the firm of Rossell & Thayer, Naval Architects & Marine Engineers, Philadelphia, Pa.

The above specifications as to spinning and packing are trade customs.

One of the best known manufacturers of marine oakum advertises his No. 1 grade of machine spun oakum as averaging about 50 feet to the pound. When a calking machine is used threads 40 feet or less to the pound for the hull, and about 55 feet for decks, have been found to be the most economical.

Machine spun oakum costs about one cent per pound more than the unspun oakum, whereas the cost of spinning it by hand will usually be several times that amount. Moreover, it contains considerably less waste than the unspun oakum. As the spinning, however, is a part of the calkers' work, they sometimes have to be taken into consideration when determining which kind to buy.

With regard to the 30 percent maximum limit of tar, before specified, the writer understands that the most used make of high grade marine oakum contains only 15 to 18 percent of tar. Thorough impregnation or absorption of the tar by the fibers is essential in order that they shall be impervious to water and this necessitates a certain amount of seasoning of the oakum.

It is very poor policy to use on any vessel anything but No. 1 grade of oakum because the cost of the initial calking is a relatively small item and of that cost the labor element is by far the greater part. Subsequent calkings are at the expense of dry dock charges, loss of service of the vessel and other undesirable features.

On account of the high percentage of labor in the calking cost and the knowledge of or ability to determine how many feet of single thread one man or pair of men will do per day, an estimate of the amount of calking material necessary for any vessel is more important from the point of view of the number of feet of thread than of its actual weight.

The following table shows the amounts of oakum and calking cotton that should fill the seams when the planks are properly laid up and the proportions of cotton and oakum that it is desirable to use. It will be noted that the total is one thread per inch of planking thickness.

Thickness of Plank, Inches	Threads of Cotton	Threads of Oakum
2	1	1
3	1	2
4	1	3
5	2	3
6	2	4
7	2	5
8	2	6

Data in possession of the writer of actual amounts of oakum and calking cotton used on wood hulls of 200 feet length and over indicate that a fairly close approximation to the weight of oakum and calking cotton required for seams that are properly laid up can be obtained in the following manner, using for L, B and D, the length from the fore side of the stem at the deck level to the aft side of the rudder post, the breadth molded and the depth molded. Thicknesses are in inches and other dimensions are in feet.

Hull to depth deck — $L \times (B + 2D) \times$ average thickness planking .... (a)
Complete calked decks — Number $\times L \times B \times$ thickness of decking .... (b)
Complete calked bulkheads — Number $\times B \times D \times$ thickness of bulkheads .... (c)
Erections, shaft tunnel, ceiling and other calked work — Area of surface in square feet $\times$ thickness of planking.. (d), etc.

$$\text{Weight of oakum} = \frac{(a) + (b) + (c) + (d) + \text{etc.}}{100} \times 3.5$$

Weight of cotton = about 1/5 the weight of oakum

Calking Cotton

Calking cotton is made from the short stuff or linters resulting from the carding of cotton and from sweepings and similar waste product, which is recarded and spun into threads. It is sold in small bundles and in bales of 50 and 100 pounds. When sold in bales the threads usually run about 50 feet to the pound but they can be readily subdivided to any extent desired. When in small packages the threads are usually thinner. It is graded according to length of fiber, uniformity and cleanness, and the best grade generally obtainable is none too good or too clean.

Cotton is used for calking seams in thin planking which are too small to take oakum efficiently and should be used at the bottom of all seams. It works into the point of the V with less danger of forcing it all the way through; it protects the oakum from decay due to contact with bilge water; and as it is of longer life than oakum it will form a base for any necessary subsequent recalking. In some cases where a vessel is calked entirely with cotton subsequent recalking will be done with oakum.

The preferred number of threads to use and the amounts required have just been considered under the heading of oakum.

Pitch

As before stated, pitch is used to protect the oakum, which is driven well below the face of the planks leaving space for this or some other protective covering. It must be of a nature that will not crumble or crack in cold weather or liquify or run in hot weather, which calls for a good degree of elasticity and a melting point around 150 degrees F. There are three kinds of calking pitch on the market—pine tar pitch, asphalt pitch and coal tar pitch.

Pine tar pitch, which results from boiling down pine tar, is the old and tried material that stands up in all weather conditions, is elastic and scrapes clean. The difference in cost between it and other pitch is not usually sufficient to warrant the use of any other kind on marine work.

Asphalt pitch has given good service in a number of cases and has demonstrated a considerable degree of elasticity but it is not the equal of pine tar pitch.

Coal tar pitch, which is made from the distillation of gas house and coke oven tars, is an inferior article and in tropical service will soften and work out of the seam. Some of the older wood shipbuilders consider that it acts injuriously on the oakum, paint and wood in contact with it but it is doubtful if this is true of the present day article produced by reliable manufacturers.

During the recent war the Forest Service reported a possible supply of hardwood pitch but as there was an ample supply of pine tar pitch this was not followed up.

Marine Glue

There are a number of good marine glues on the market, designed to replace pitch as the final filling of seams and protector of the oakum; they sometimes have names such as elastic seam composition, elastic calking compound, etc. Marine glue is preferable to pitch for deck seams on everything except barge, tugboat and other rough work where its slightly higher cost might not be warranted. It should be ordered from a manufacturer whose product has been proved to be successful rather than on the basis of melting point or composition.

In addition to the filling of seams, marine glue is also used in joints of joinerwork of yachts and other craft where special provisions for watertightness are desirable.

Calking Cement

This is simply pure Portland cement mixed up with water to the proper consistency, with the addition of a handful of powdered chalk or lamp black per bucket to retard the setting action. Its use is confined to the seams of the outside planking of wood vessels.

It is objectionable on a new vessel because the shrinkage of the planking and other reasons usually necessitate early

recalking, and the removal of the cement is apt to damage the edges of the calking seams. It is of particular value on unduly wide seams of old vessels. It is also of value against teredo attack.

Where cement is used the oakum and the seam beyond the oakum should first be painted with a seam paint.

Seam Paints and Composition

These are usually proprietary products marketed by specialists in this line and by paint manufacturers. The compositions take the place of pitch, glue or cement in filling out the seams and some makes are used without any preparatory painting of the seams. With other makes a preparatory painting is advisable and the paint for this purpose is usually the composition in liquid form. On small seams paint alone will suffice.

The paints and compositions should be waterproof, durable and where used on the hull below the waterline for salt water service preferably of a nature poisonous to marine wood borers. The best guide to their selection is the results of past service. A mixture of white lead and tallow gives good service in hull planking seams.

Calking Wedges

As before stated, wood calking wedges are sometimes used for the inside ceiling of wood vessels and for floating dry docks and other special work. They add greatly and most beneficially to the stiffness of the structure.

The wood used should have the property of swelling considerably when wet, and white pine is ideal for this purpose. White pine calking wedges are a staple article of commerce. The heartwood of thoroughly seasoned bald cypress, red cedar or Douglas fir may be used, subject to classification or other necessary approval.

A convenient size of wedge is 4 inches deep, with a thickness of 7/16 inch at the butt and tapering to a point, and with a width of 3⅝ inches at one end and 3¼ inches at the other. Alternate wedges having the larger width at the point are first driven and then the intermediate wedges having the larger width at the butt are driven between them. The seams have to be properly outgaged and carefully reamed and cleaned out.

Lead and Tallow Mixtures

These mixtures, while often used to cover up poor workmanship, are sometimes unavoidable for stopping up leaks in otherwise inaccessible places in both steel and wood construction. They are forced into the crevices with compressed air or mechanical pressure from a so-called gun, through a hole drilled or bored in a location that will communicate with the spaces requiring to be filled up.

For watertight work on steel ships a good mixture is a putty made by mixing red lead powder into white lead paste, with a little whiting added where necessary to harden it. For oil tight work on steel ships a good mixture is a putty made by adding sifted powdered Portland cement to equal parts of liquid pine tar and shellac.

For wood ships a mixture of red lead and tallow is used. In and around deadwoods the mixture is made thin but where the trouble is localized a thick pasty mixture is used. The tallow stops the leak and the red lead prevents its caking too quickly and also poisons it so that the rats will not eat it. White lead and tallow to cover the calking in planking seams have been previously referred to.

Packing

Packing is sometimes used as an aid to watertightness in steel to steel calking. Like the mixtures just dealt with it is in the nature of a necessary evil, with a tendency to make use of it where it should not be required. In some cases the use of packing is commendable, such as under doubling plates, along plate landings in repair work where the surface has become roughened by corrosion, and between castings and steel plating.

The packing is ship sheathing felt or thin canvas thoroughly soaked in red lead or some bituminous compound that has been proved to give good results when so used.

President Plans Definite Shipping Policy

Expert Committee Preparing Concrete Plan of Government Aid to Shipping, to Be Submitted Early in January

AFTER several months of consideration the administration has decided that it is impossible to build up an American merchant marine and dispose of the ships now owned by the Government to private companies without some kind of a ship subsidy. President Harding has indicated his intention of going before Congress early in January with a special message in which he will advocate a concrete plan of Government aid to shipping in complete detail and the legislation on this subject is expected to form an important part of the program for the regular Congressional session which opened on December 5.

The exact form of the plan is yet to be determined but is being worked out by the Shipping Board with the assistance of a committee of outside experts working under the direction of Commissioner Meyer Lissner. The White House had previously let it be known that the President had been advised by the State Department that it would be unwise and imprudent to enforce Section 34 of the Jones law, and that the President would recommend a substitute to Congress. The subsidy plan is to be the substitute which will assist the development of American shipping by other means than by a policy of discrimination. In this connection so many objections have also appeared to the enforcement of Section 28 of the merchant marine law, intended to restrict preferential rail export and import rates to freight shipped in American bottoms, that there have been many predictions that it will not be applied.

Form of Subsidy

The study being made under the direction of Commissioner Lissner, which is now taking form, involves not only the question of the amount of assistance required but also of the form of the subsidy, whether a direct subsidy such as the proposal of the shipowners some time ago for a payment of $5 per gross ton per year, or aids, such as for example a provision that 50 percent of the immigrants allowed to enter the United States shall be required to travel on American ships. The recommendations to be made to the President will cover what is necessary in each route or type of service, including what is necessary to take care of the wage differential.

It is believed that some form of subsidy will hasten the time when it will be possible for the Shipping Board to get out of the business of ship operation as it will increase the chances for selling the Government-owned boats. The reasons advanced as to why a ship subsidy is necessary are

first, to enable the American merchant marine to compete with long-established foreign competitors who have been aided by their own governments, and to overcome the higher cost of construction in this country as well as the higher wages paid to American crews.

The proposed 10-year naval holiday is also advanced as a reason for giving some encouragement to shipbuilding on the ground that, if naval construction is practically shut off for that period of time, shipbuilding in this country will become a lost art.

One of the plans under consideration is, in place of imposing discriminating duties on traffic brought to this country in foreign vessels, to devote a percentage of all the duties actually collected to the aid of American ships.

President's Special Committee

Those who are making the study of ship subsidies for the Board are: Professor Emory R. Johnson, of the University of Pennsylvania; W. L. Marvin, vice-president of the American Steamship Owners' Association; Rear-Admiral H. H. Rousseau; Admiral C. S. Williams, Daniel H. Cox, naval architect, Grosvener N. Jones, authority on ship subsidies; Norman Beecher, admiralty counsel of the Shipping Board. Those studying the insurance phase of the situation are: Professor William Leslie, of the University of California; Dr. S. S. Huebner, professor of insurance at the University of Pennsylvania; W. C. Rader, in charge of marine insurance for the Standard Oil Company of New Jersey; B. K. Ogden, in charge of marine insurance for the Shipping Board, and Vice-President W. J. Love of the Emergency Fleet Corporation.

In his address to Congress at the opening of the session on December 6 President Harding discussed merchant marine affairs as follows:

The Jones Act

"The previous Congress, deeply concerned in behalf of our merchant marine, in 1920 enacted the existing shipping law, designed for the upbuilding of the American merchant marine. Among other things provided to encourage our shipping on the world's seas, the executive was directed to give notice of the termination of all existing commercial treaties in order to admit of reduced duties on imports carried in American bottoms.

"During the life of the act no executive has complied with this order of the Congress. When the present administration came into responsibility, it began an early inquiry into the failure to execute the expressed purpose of the Jones act. Only one conclusion has been possible.

"Frankly, members of House and Senate, eager as I am to join you in the making of an American merchant marine commensurate with our commerce, the denouncement of our commercial treaties would involve us in a chaos of trade relationships and add indescribably to the confusion of the already disordered commercial world.

"Our power to do so is not disputed, but power and ships, without comity of relationship, will not give us the expanded trade which is inseparably linked with a great merchant marine. Moreover, the applied reduction of duty, for which the treaty denouncements were necessary, encouraged only the carrying of dutiable imports to our shores, while the tonnage which unfurls the flag on the seas is both free and dutiable, and the cargoes which make a nation eminent in trade are outgoing, rather than incoming.

Plan for Ship Subsidy

"It is not my thought to lay the problem in detail before you today. It is desired only to say to you that the executive branch of the government, uninfluenced by the protest of any nation, for none has been made, is well convinced that your proposal, highly intended and heartily supported here, is so fraught with difficulties and so marked by tendencies to discourage trade expansion that I invite your tolerance of noncompliance for a very few weeks until a plan may be presented which contemplates no greater draft upon the public treasury, and which, though yet too crude to offer you today, gives such promise of expanding our merchant marine that it will argue its own approval.

"It is enough to say today that we are so possessed of ships and the American intention to establish a merchant marine is so unalterable that a plan of reimbursement, at no other cost than is contemplated in the existing act, will appeal to the pride and encourage the hope of all the American people."

The Most Interesting Job in the Yard

Here is another contender in the controversy over which is the most interesting job in the yard. In the October and November 1921 *issues were published the claims of a machinist in the engineering department of a ship repair yard and of an engineer in the office of a large shipyard. Now comes a veteran who not only has designed engines but has erected them in the shop and operated them on board ship. How does YOUR job compare with these? Tell us about it and why you think it is the most interesting job in the yard. Who's next?*

THE letter by "Nulli Secundus," page 761, of the October issue, interests me. If a workman of any kind, in any branch of the mechanic arts, is really in love with his work naturally he will think that *his* work in particular is "the most interesting job in the yard." This is what might be called "departmental pride," which is justifiable as long as it does not disbar co-operative effort in production as a whole. So, the correspondent who signs himself as "second to none" thinks the machine work part of the yard as a whole is "the most interesting job." Well, it is interesting but, to me, not the *most* interesting by a good deal.

I have been engaged in various operations in marine engine works and shipyards, from the drafting board to installing the machinery "on board," and then operating that machinery as an engineer's officer of the watch, for several years. (Incidentally I held a chief's unlimited tonnage certificate.) Therefore, I would like to add my "say so" in regard to the matter.

I think the most interesting job in the yard is the erection of the engines in the shop, and next to that, the installation of the engines in the ship. The erecting engineer *must* know something more, both in detail and as a whole, than is required of any of the "tool hands" (or "machine hands," which is perhaps the better expression). The bringing together, the assembling of the various parts of the engine requires more than merely bolting them together. Measurements must be checked up from blueprints and dimensions compared for accuracy of the work as turned out by the various machines involved. Mistakes may be made, and pass unnoticed, while the process of machining is going on, but those mistakes must be discovered in the process of erection, else serious consequences may follow.

In my contention that "the most interesting job in the yard" is the assembling and erecting of the various parts which make up the whole, let us consider the erection of a three cylinder, triple expansion reciprocating marine steam engine. I shall touch only the "high spots" at this time as time and space do not permit of going into a full and detailed description and explanation.

We will assume a suitable shop in all aspects in which such an engine may be built from start to finish. The various parts have been designed, patterns and castings made,

forgings turned out from the smith's shop, and all these have been "laid out" from blueprints or other drawings, so that the various machine hands can finish the parts to the required dimensions. This involves all kinds of machine work, such as planing, boring, drilling, turning, slotting, milling, shaping, etc.

The bedplate, having been planed (i. e., the upper surface, upon which the feet of the six columns rest, the openings for the six main shaft bearings to be housed, and also the upper surface of all the housings), is now ready to be "set up," either on the floor or in a pit for that particular purpose as conditions may require. In some work the overhead traveling crane which must handle all the heavy parts is not sufficiently high to permit of a very large engine being set up on the floor level, hence the necessity for a "pit."

The bedplate is set level by wedges under it, the spirit level being applied to the planed surfaces on top. During the erection of the entire engine the bedplate is tested for possible settling down out of level, and, if so found, a readjustment of the wedges corrects the trouble.

Next, the columns are set up, the tops of the six columns and also the feet are supposed to be correctly planed, so that they are exactly the same length and, also, so that when secured by the bolts at the base to the bedplate the tops of the columns are in the same plane and level as the bedplate is. As well as this, the planed faces of the crosshead guides must be parallel, or nearly so, as measured by a gage applied at the top and bottom ends of each pair of columns.

Sometimes it happens that the three planed surfaces of each column are not exactly true with one another, as discovered when setting them all up on the bedplate and gaging distances, etc. In that case, the foot of the column, or columns, must be faced to bring the surfaces true.

After all the columns have been "trued" up and securely bolted to the bedplate through two or more of the holes in the base of each column and in the bedplate, they are reamed and properly fitted bolts are driven in and secured by nuts. Thus the columns are prevented from twisting or getting "out of line" or "out of true" in any direction. Proper precautions are also taken to prevent the tops of the columns springing inwards, towards each other, until the cylinders are ready to be placed thereon. The correct location of each pair of columns, i. e., those for the high pressure cylinder, those for the intermediate cylinder and those for the low pressure cylinder, has been determined by the use of plumb bob centerlines between each pair of columns, gaging between the falls of the guides and by testing with a centerline running fore and aft through the bearings in the bedplate.

Thus by these means let us say that the six columns are correctly set on, and properly secured to, the bedplate, all in correct relationship to one another and according to the dimensions and distances as specified in the drawings. After this the whole structure is tested again for being level.

Next in order is the testing of the tops of the six columns for being in the same plane, level in a fore and aft direction, as well as in the athwartship direction. The test is made by the use of long metal straight edges and also by the use of a spirit level of good design. The top surfaces of the columns must be made right, for, if they are not, the cylinders will not be truly in line. Shims might be used to make up for inequalities of the column tops, but it is better to reface the tops of those columns that are "out" and thus make a correct job of it.

In the meantime, the cylinders have been bored and the various surfaces planed, including the feet, which are to be secured to the tops of the columns. Assume the cylinders to be finished—as far as is necessary for placing them on top of the columns—which means that they are all true with one another, both with regard to the bores and also the planed surfaces, and that the feet are all in one plane, so that when the entire "block" is placed upon the column tops the faces meet and require no "shimming" or "springing" to bring them together.

Then centerlines are run through each cylinder, so as to intersect the horizontal centerline through the bearing housings, and the cylinders are correctly set according to the requirements of the drawings. After the cylinders have been correctly located so as to be in line fore and aft and athwartships, the feet are securely bolted to the tops of the columns. Here, also, two holes (or more if desired) are reamed and fitted with driven-in bolts. All the bolts fitted in the reamed holes should be marked for their respective places, so that after dismantling the engine and setting it up in the ship, the bolts will be correctly placed and all the parts come exactly right again.

So far we have the principal heavy parts of the engine erected and in true relationship and alinement. It is now a matter of correctly assembling the minor parts and by centerlines, gages, levels, etc., set them also in their correct positions, using the drawings as guides for dimensions and location of various parts.

I think enough has been written to support my claim, that the erection of an engine is the most interesting job in the yard.

The erector deals with, and is concerned with, the *whole* machine, while the various machine hands are concerned only with their individual parts to be made. They cannot feel the same interest in the machine being constructed and "set up" as the man, or men, who are employed on the actual erection work. Even the workmen themselves look upon an erector as a somewhat superior man. Why? Because he is engaged in a superior work—a most interesting job. And then, who are the men usually selected "to go down to the sea in ships" as engineers? The men who produce the individual parts of the engines? No, seldom, if ever. The men chosen are those who erected the engine, assembled the parts and made it possible for the machine as a whole "to run" and serve the full purpose for which it was made.

Brooklyn, N. Y. CHARLES J. MASON.

Shipments Via Panama Canal

"IT is evident that the Pacific coast is taking advantage of the cheap transportation which the Canal affords for bulky commodities to eastern United States and Europe," said E. S. Gregg, chief of the transportation division of the Department of Commerce, in a statement on the Panama Canal in which he submitted detailed statistics showing increased tonnage moving via the Canal.

"Steamers in the intercoastal trade are endeavoring to equal the time made by the transcontinental railroads. Oranges and lemons have been shipped from California to New York by water in 19 days. While the railroads occasionally move fruit across the continent in two weeks, the average time is probably not under 20 days. A saving of about 25 percent in rates is effected by the all-water route. It is claimed that the percentage of decay in fruit arriving at Atlantic ports by water is less than when shipped by the rail routes.

"Intercoastal trade through the Canal shows a pronounced increase during this year as compared with 1920.

"During the war and as long as rates were high on foreign traffic, ships were induced to forsake coastwise trade. Since the slump in rates, however, many American ships have returned to the protected intercoastal trade, and an increasing amount of cargo is being carried between the Atlantic and Pacific ports of the United States by water.

"Europe is taking large quantities of Pacific Coast wheat this year; during the first eight months of 1921, 506,058 tons were shipped to Europe, as compared with a total shipment of 749,447 tons of all kinds of cargo during the 12 months of 1920."

Compounding the Internal Combustion Engine*

By Elmer A. Sperry

The compound combustion engine is light compared with the normal Diesel, being in special cases less than one-tenth, and in some instances less than one-twentieth, the weight for the same output. Its mechanical efficiency is extremely high, and a distinct gain in overall efficiency from fuel to shaft has been made, as well as a very definite gain in simplicity, direct performance and smoothness of the crankshaft diagram. This has been achieved while adhering to the four-cycle operation. This paper presents the results of research by the author extending over a series of years, during which not only has the high-pressure principle been thoroughly established, but all the important requirements have been worked out, and finally an engine embodying practically all the advantages has been subjected to long continuous runs.

IN America, a group headed by the author has been engaged on the problem of compounding the internal combustion engine for upward of thirty years. A number of engines have steadily followed each other, each involving improvements resulting from previous experience, until the essential problems have been conquered. Not only has the principle been thoroughly established, but all the important refinements have been worked out, and finally an engine embodying practically all the advances has been subjected to long continuous runs. Data almost invaluable to the art have been secured, together with a series of indicator cards and diagrams that exceed a thousand in number.

The outcome has been that the various prophecies of thoughtful engineers in the past have been more than fulfilled and there is every evidence that the heavy-duty compound combustion engine is everything that was hoped for. It is light compared with the normal Diesel, being in special cases less than one-tenth, and in some instances less than one-twentieth, in weight for the same output. Its mechanical efficiency is extremely high, a distinct gain in overall efficiency from fuel to shaft has been made, as well as a very definite gain in simplicity, direct performance and smoothness of the crankshaft diagram. This has been achieved while adhering to the best practice, namely, four-cycle operation.

Compounds Lighter and Cheaper

The lightness and simplicity of the compound solves the capital-charge factor automatically. Engines of this type weighing only a fraction of the weight of the present Diesel will inevitably be found to be much less in first cost as well as in cost of upkeep.

Our own Government has come forward with orders for an initial engine which, together with orders from other sources, is now under construction. To illustrate to what low figures the compound principle can be relied upon to bring the heavy-oil engine, it should be stated that among these orders is one now under construction to weigh about five pounds to the brake horsepower. This may be looked upon as extreme, but the designed weights and finished parts as they now stand are below this figure. The old single-stage compression is discarded in the compound and the modern method of two-stage compression is adopted.

Chilled Surfaces Reduced

Supercharging or compressing in two stages gives the controlling advantage in that a very much larger unit volume of gases may be handled. The clearance spaces may be many times the size of those in the Diesel, and yet it is perfectly simple to bring these large volumes up to the requisite pressure and incandescent temperatures at the instant of fuel injection.

While retaining all of the chilled walls that are necessary for proper handling of the lubrication, still a gain is made on the order of 60 percent in the extent of these chilled walls in the compound as compared with the simple engine.

Solid Fuel Injection

With the large clearance volume we no longer have difficulty with solid injection, nor do we have any difficulty in using a wide range of heavy fuels. In the compound engine the clearance volume is so large that the entire high pressure piston displacement causes it to lose only a fraction of its pressure, thus bringing to the second stage, or low pressure, both ample volume and pressure so that this piston (representing 6, 8 or even 10 times the area of the high pressure) is driven to the end of its stroke with pressures still above the atmosphere.

Much Greater Expansion, Higher Efficiencies

In this way the engine yields an expansion ratio based on gage pressures, which instead of being 3 or 4 to 1, as in the case of the automobile engine, or about 12 to 1 in the Diesel, can be made as high as 120 to 1. A higher return and greater efficiency from the fuel are secured because of the lower temperature of the exhaust.

Utilizing the Detonation of Fuels

Through a research extending over a year and a half or more, conditions were discovered by means of which "detonation" of the fuels may invariably be secured. The author found that the *thermodynamic efficiency was higher in case of high detonation diagrams* than with low. Our work has been toward realizing these high efficiencies by developing instead of suppressing this high-intensity combustion. One of the achievements of high-intensity combustion is better thermal efficiency and a still further reduction in the exhaust temperatures.

Elimination of Losses in Transfer

In early attempts at compounding it was found that prohibitive losses would occur in the transfer, due to the falling pressures while filling the low pressure clearances. A complete solution of this is found in a special adaptation of the process of "cushioning"—closing the exhaust valve at a predetermined point before the out-stroke end, trapping a little of the hot gases and cushioning them up to the transfer pressure so the transfer valve opens under conditions of equal pressure on each side. There is, therefore, no flow of gases except that due to the slow starting of the strokes of the two pistons. There are practically no losses sustained in cushioning; the power of compression is returned very completely on expansion. In this unique adaptation of cushioning the additional advantage is secured of preventing all erosion due to high velocities of the hot gases over the transfer seats. These seats are amply jacketed and are found to remain smooth, bright and perfectly sealed over long periods. It is incidentally found that in cushioning, the

*Extracts from a paper read before the American Society of Mechanical Engineers, New York, December, 1921.

adiabatic compression of the hot gases brings with it an equality of *temperatures* as well as pressures, so there is neither loss in pressure nor temperature at this critical point of transfer and the efficiencies are carried at high values throughout the cycle. In the compound engine the exponents hold very closely to the adiabatic throughout the cycle due to less cooling, owing to the very low ratio of chilled wall surfaces to unit volume of power gases and the large unit volumes employed.

An important feature of compounding is the complete suppression of all preignition. All the early part of the compression occurs entirely extraneous to the combustion chamber, where air only is handled, and only the latter part or second stage of the compression occurs in the combustion cylinder, so the engine is simplified because no troublesome and often leaky safety valves or pressure relief valves are required or fitted.

The Transfer-Valve Problem

The transfer valve considered as an exhaust valve is called upon to handle much hotter gases than ever heretofore. A difficult situation is here presented. Are special materials necessary and how can the valve successfully perform this duty? It is known that the exhaust valves of the Liberty motor run red hot and the stems white hot, and yet they are handling gases of lower temperature than are here present.

Compression in the compound is by the modern two-stage method. Air is admitted to the combustion chamber under comparatively high pressure and although it is warm, yet with each atmosphere of pressure its cooling powers are doubled. Air at 100 pounds thus has seven times the cooling power of atmospheric air, seven times the weight and seven times the molecules in contact for cooling. In forcing the high-pressure piston down, air must pass some port in entering. Now, as a matter of fact, this port is in line with the transfer port and the induction valve itself rides on the back of the transfer valve in the form of a hollow sleeve *I* (Fig. 2) seated directly on the top of the transfer valve *T*. The back of the transfer valve is provided with greatly enlarged radiating and cooling surfaces presented to this cooling air and powerful convection currents are constantly acting when sealed. Moreover, this air when entering is at high velocity and gushes down through and bathes the deeply serrated surfaces of the back of the transfer valve, licking up the heat very completely in its inward rush.

Intensive Cooling Effective

Now in following out the cycle, it will be noticed that this is the very step that follows directly on the heels of the transfer of the hot gases and continues throughout the next quarter cycle and through the entire descent of the high-pressure piston, which in this way delivers a real power stroke to the crank with mean effectives in some instances greater than the mean effective pressures of the ordinary Diesel, thus returning some of the power taken to drive the supercharger or first stage pump. If the transfer valve is intensely heated on its under surface (see *T*, Fig. 2) and is then instantly intensely cooled on a surface five times as great, it will certainly strike and maintain a heat balance which in practice is found to be extremely low, only about one-half the temperature of the Liberty valves, nowhere nearly approaching red heat nor the temperature of normal Diesel exhaust valves under load conditions. Here is the crux of successful compounding, the great obstacle which has always been looked upon as practically insurmountable, solved by an extremely simple and straightforward method. In fact, the temperatures of the valve are lower than the calculated temperature balance because of the high velocity of the induction gases from the receiver.

Again, the heat in these gases absorbed from the hot valve is useful inasmuch as it is the auto-ignition temperatures as well as pressures that are required at the end of the compression curve. Here a useful heat transfer and pure regenerative process is carried out. The seats give no trouble because they are backed by the ample water jackets and, in fact, the whole transfer valve gear operates continuously and successfully and is found to be in perfect condition after hundreds and even thousands of hours of operation. They require practically no attention and are seldom ground in. This is exactly as it should be, considering the very low temperatures at which this valve really operates.

How Lightness Is Obtained

The question often asked is, to just what is due the smallness and lightness of the compound engine? It is this: In the four-cycle Diesel we have the tonnage of metal due to the presence of high pressures, operating at a ridiculously low material efficiency because these high pressures persist only about 2½ percent of the total time. The Diesel card rises abruptly and immediately falls. All the rest of the time, over 95 percent, either low pressures or no pressures at all are present, whereas in the compound the pressures *persist* and we are dealing with great blocks of power. Although the pressures are not materially higher than in Diesel

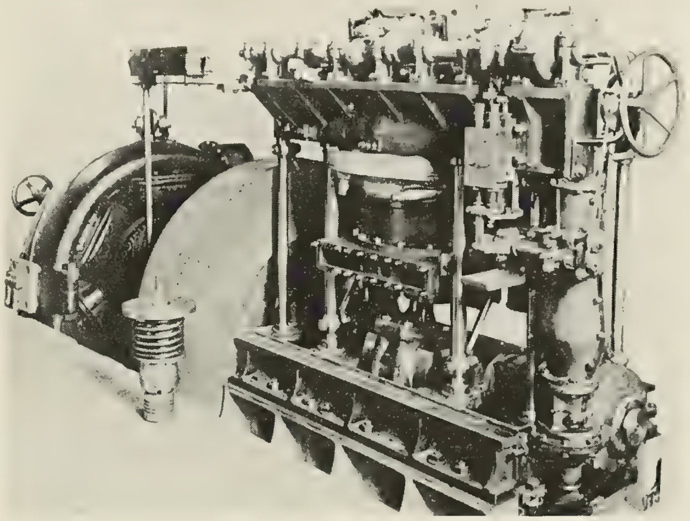

Fig. 1.—Marine Compound Oil Engine Built for Heavy Duty

practice, they are made to persist practically clear across the card, producing very large gross mean effectives. This is instantly followed by another line clear across the card, again producing another large gross mean effective in the low-pressure cylinder when referred to the high-pressure area, all from a single fuel injection. Instead of 60 to 70 pounds net mean effective to the crank, delivering its power through a few degrees only of one stroke in four, in the compound we have two net mean effectives, each of 300 or 400 pounds per square inch, succeeding each other and covering two strokes out of the four from a single fuel injection, giving very much better crank-effort distribution for power purposes.

The point of paramount interest is that these two large blocks of power are secured *not by any material increase of pressures*, but by using large quantities of power gases, and "hanging on" to the pressures we have in those gases throughout practically two complete strokes, clear across the card twice, thus abstracting much more of the power they contain before exhausting. Suppose these to be 330 pounds per square inch each. Added they make 660, which is easily ten times 62 pounds, a net mean effective not infrequently met with in ordinary Diesels. In an engine of simple construction giving ten times the net mean effective to its crankshaft and well distributed, there should be no good reason why it should weigh more than one-tenth the weight of the present Diesel.

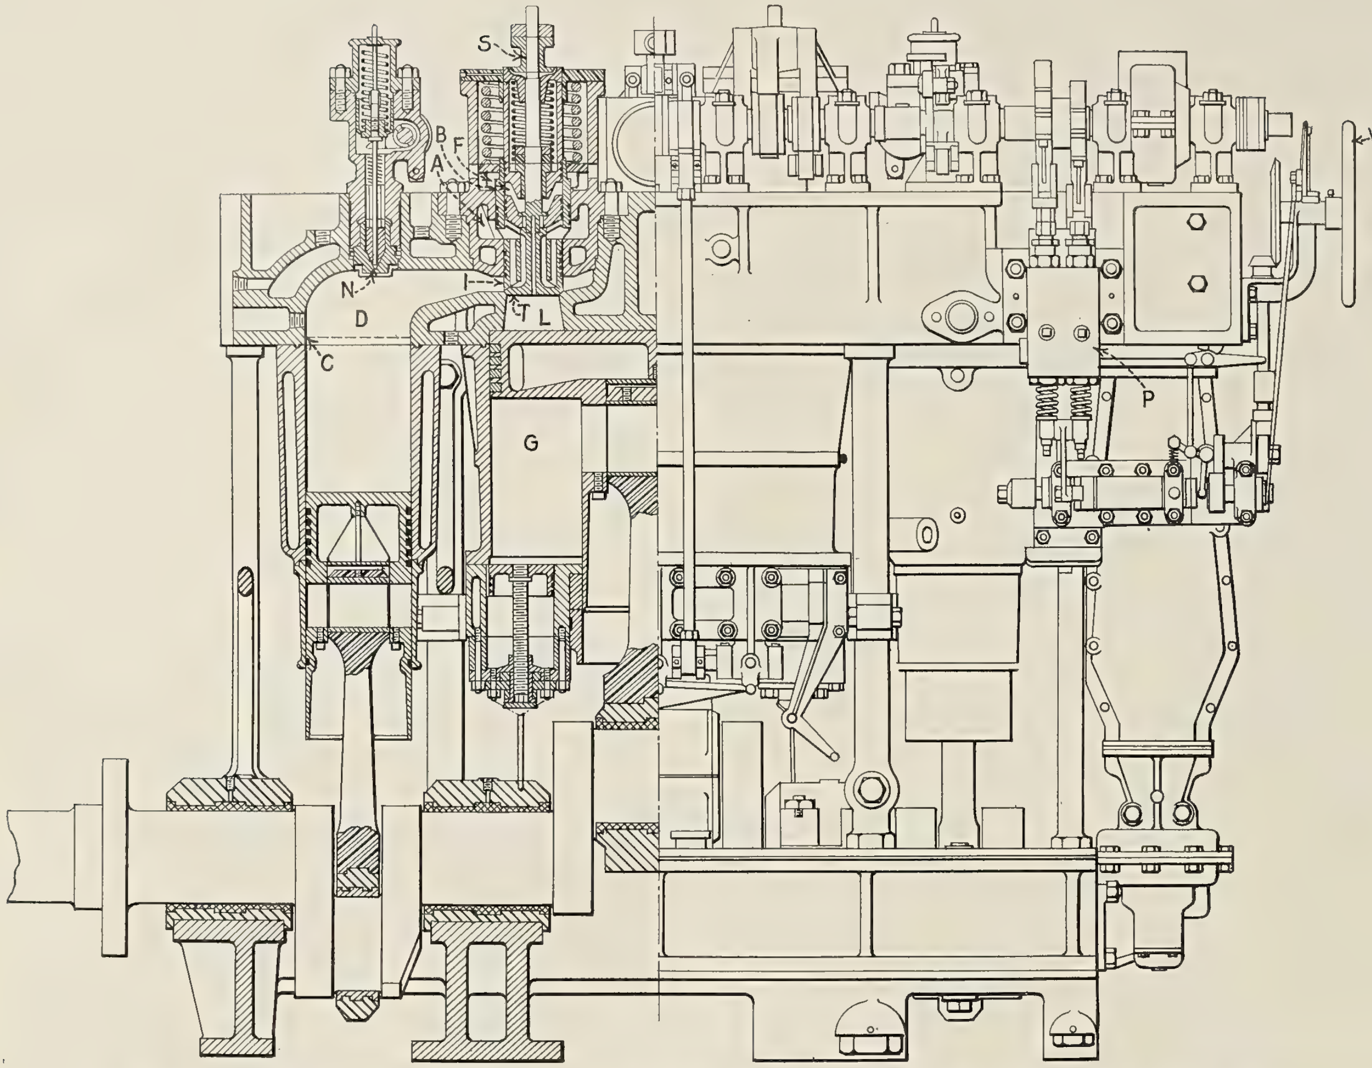

Fig. 2.—Longitudinal Section and Elevation of Sperry 10:1 Compound Engine Built for Heavy Duty

The power gases work in the Diesel about 120 degrees of arc and in the compound 315 degrees, or 2.6 times as long; or, considering the points of "cut-off" in each, the true expansion curve is 3⅓ times as long, which accounts for its large mean effectives and higher economies.

Proper Ratio for Compounds

As to the proper ratio for compounds; engines of 10:1 ratio of low-pressure to high-pressure cylinder areas, also 8:1 and 6:1 have been made, operated and studied, the smaller ratios being at present considered more desirable. The weight factor does not change materially with changes in ratio in this region. The low-pressure piston operates two cycle. The power distribution and the weight of the reciprocating parts both equalize best at about 6:1. This makes a perfectly balanced unit, the end masses equaling and also moving oppositely to the central. The two full power impulses following each fuel injection are also about equal. Thus full *four-cylinder performance* is secured with only three cranks and two extra power impulses are delivered on the induction stroke, making six power impulses for each cycle.

Another unusual advance should be noted, viz., complete reversibility and self air starting are secured without additional valves or cams over the simple, one way engine without air starting, there being no difference in this regard. Again comparing the full-reversing, air-starting compound unit with a similar four-cylinder Diesel of any prominent make, delivering the same number of primary power impulses to the crank, the latter has 16 valves and 32 cams. The former operates the same cycle with two extra power impulses over the Diesel with 5 cams driving 7 valves.

Three-Stage Compressor Eliminated

Doing away with the three-stage air injection pump, its intercoolers and general complexity, is another important simplification. One United States builder stated recently that an excess of 11 percent of the entire power of the engine is absorbed for driving these pumps.

As stated, solid injection only is used in the compound and the engine is controlled entirely by the fuel, viz., by lifting and timing the fuel valves. The constant-pressure trunk system is used with an accumulator in the line, the pumps simply working constantly against loaded relief valves which may be adjusted at will. Two very small plungers are constantly acting. The pistons, accumulator and the fuel valve stems are ground in and require no packing.

Types of Compound Engines

Fig. 1 shows a 10:1 compound engine, built for heavy duty. Although this is a small marine type with high-pressure cylinders 7-inch by 11-inch running at 400 revolutions per minute yet the size of the crank pitman-end in the lower center of the engine reveals the ruggedness of these parts. The fuel pumps are also shown here and the connection to the governor. The camshaft is on a shelf at the top of the engine to one side and is driven by skew gears. The electric generator forming the full load of this engine is shown in the background and one of the transfer valves with its bonnet cover stands on the floor in front of the

engine. The comparatively small size of the engine, although in the foreground, is notable. The compound works at a piston speed of about 700 feet per minute and its generator would be still smaller in comparison, should it be worked at the piston speed of about 900 feet per minute of the large engine.

The large size and weight in the Diesels extend to all makes in somewhat different degrees. A line of Diesels made in the United States is reported to weigh 512 pounds per brake horsepower, while the compound in Fig. 1 weighs less than 30 pounds per brake horsepower.

Internal Construction of the Compound

Fig. 2 shows an elevation to the right of the center, and longitudinal section to the left, of the engine shown in Fig. 1. The two high-pressure or combustion pistons on their out stroke are at the ends, and in the center is the low-pressure at its extreme in stroke. The sturdy construction is indicated by the size of the crankshaft, about 50 percent larger than in any other combustion engine of which the author has knowledge, approaching, as it does, the bore of the combustion cylinders themselves. The fuel pumps *P* and the control and manipulating wheel *W* are shown in elevation to the right. To the left the large dome of clearance *D*, forming the combustion chamber of the compound, stands out in marked contrast to standard Diesel practice, which is shown by the little space *C* between the solid horizontal line at the base of the clearance and the dotted horizontal line just above. The dome is large and forms an upward extension of the combustion cylinder, extending also to the right in a large sweep surrounding the transfer valve *T* which seals the transfer port *L*. The sleeve-like induction valve *I* is shown seated on top of the transfer valve and is controlled by the cam-operated fork *F*. The transfer valve and sleeve are lifted by a fork not shown, located in thimble *S* near the top of the stem. The first-stage annular compression pump *G* surrounding the trunk piston below the low-pressure piston proper, delivers its air to a small receiver, which in turn discharges to the cored port *A* surrounding the induction sleeve *I*, the cooling action of which has been described. The little balancing cylinder *B* sustains a permanent connection with the low-pressure cylinder. The solid-fuel injection valve and nozzle *N* are placed approximately over the center of gravity of the large masses of air in the clearance dome *D*.

It is understood that the two high-pressure cylinders are operating four cycle, one 360 degrees back of the other, discharging alternately into the low-pressure, which therefore works two cycle and delivers power on each down stroke.

Ordinary Standard Construction and High Mechanical Efficiency

The illustrations show the simplicity of the details, there being no part with which the ordinary engine builder is not perfectly familiar, nothing about the cylinders, pistons, rings or valves that lies outside ordinary good engine practice and construction. The radiating fins on the valves and the piston clearances and tolerances are the only points that vary to some small degree from the best Diesel practice.

A point of interest arises regarding the mechanical efficiencies of the compound. The two high-pressure cylinders in this case might be considered as constituting a two-cylinder Diesel. By separating them and adding one crank and the low-pressure piston between them, an increase of no less than seven times the power to the crankshaft is realized in this engine. Pursuing this one step farther, to obtain this increase of power at the shaft, it is perfectly apparent that we have not added, nor are we driving, seven times the machinery. We are driving probably about twice the machinery, giving one apparent reason for the very high mechanical efficiency observed in this engine. These efficiencies have again secured an additional check by motoring the engine and taking a number of sets of cards, in several instances indicating as high as 93 percent mechanical efficiency.

Port Velocities

In Fig. 2 the transfer port *L* to the low-pressure piston has only about one twenty-fourth of the area of the piston. The question naturally arises, what about wiredrawing through this port? This has been closely investigated and it is found that at 1,000 feet per minute piston speed, the velocities rise to 200 feet per second only at a point near the greatest velocity of piston travel. This comes from the fact that by the time the center of the stroke is reached, where the velocities are highest, the expanding gases delivering the power find themselves very largely on the low-pressure side and therefore are not required to traverse the port. It is well known that no wiredrawing, as such, exists at the velocities named.

Field of Usefulness of the New Prime Mover

To engineers versed in the problems of selecting and designing prime movers, the advantages of the compound combustion engine are readily apparent. Its light weight for a given power with resulting low first cost and capital charge, the low costs for foundations, the high speeds with consequent low costs for connected generators, the small space required and the simplicity and economy of operation are important reasons for suggesting new fields for this prime mover, which has been proven of practical value in a long series of tests under working conditions.

In connection with the development of the compound engine for marine purposes, and in order to provide any Diesel type of engine with speed flexibility equaling the reciprocating steam engine, there has been developed an electromagnetic clutch operating on an entirely new principle.* This clutch furnishes a positive yet completely elastic drive brought about by a unique correlation of two oppositely applied forces, each producing powerful torques induced and brought under perfect control by the application of a very small amount of external electrical energy. The drive has no moving parts, and is rugged and simple in design and construction. It is small for its power and therefore capable of being built in practically any range of horsepower.

Conclusion

In combustion engines the high-pressure principle is scientifically correct, having brought to the prime mover its choicest heritage, as stated, viz., the highest thermodynamic efficiency known. Broadly speaking, however, these various engines represent only the early stages of the development. The best of present embodiments in simple Diesels, though much refined as to certain details, are, generally speaking, extremely crude, their design is based on such a ridiculously small quantity of air per charge, and their material efficiency is too low to be tolerated. Further, very large structures are required to produce small powers.

This paper presents the results of research extending over a series of years, looking to the correction of these and other serious faults and to very greatly increasing the material efficiency. This is found to bring with it a number of distinct advantages and, it is believed, marks a definite advance. It is high time that this next logical step be taken so that the full capabilities of the high-pressure principle in combustion engines may be realized in service by the adoption of modern multi-stage methods. It is believed that the results for the first time announced in this paper warrant the prediction that engines employing the multi-stage or compound principle will occupy a dignified place in the combustion-engine art. If this principle should assume leadership, it will of course only be because of its demonstrated practical usefulness and general merit.

Questions and Answers for Marine Engineers

Inquiries of General Interest Regarding Marine Engineering and Shipbuilding Will Be Answered in This Department

Conducted by James L. Bates

This department is maintained for the service of practical marine engineers, draftsmen and shipbuilders. All inquiries should bear the name and address of the writer. Anonymous communications will not be considered. The identity of the writer, however, will not be disclosed unless the editor is given permission to do so.

Marine Engineering Problems

Q.(1138).—(1) In putting hydrostatic pressure on steam boilers where the capacity of the pump and steam supply is limited, how do I find the amount of power lost through friction? We often have a pump that fails to put the pressure required on boilers for test, but we are unable to figure the size of the pump to install for this work of overcoming friction losses.

(2) Suppose the coils of a fuel oil heater are full of oil at 80 degrees Fahrenheit, and all valves shut to prevent escape of oil and steam is turned in the heater to heat the oil up to 250 degrees Fahrenheit, what will be the pressure in the coils? Please give me the formula for working this problem at various pressures and temperatures.

(3) Please name the strakes of steel or iron vessels and state where they are located.

(4) What should be the thickness of the lead sleeve in the stern tube of a wooden tugboat, and how is it made and put into place?

(5) What effect on the valve gear would be caused by moving the eccentric ⅛-inch forward on a shaft of 16 inches diameter? I want a formula for working these problems for various movements of eccentric and different sizes of shaft.

(6) What is the greatest wear down of tail shaft allowed by the United States Steamboat Inspection service and American Bureau of Shipping?

A. (1138).—(1) The writer knows of no way to figure the amount of power lost in a steam reciprocating pump through friction, but would suggest that on a basis of the test pressure and plant boiler steam pressure being equal, the steam piston area should be at least 30 percent greater than that of the water piston. This allowance takes care of not only the mechanical loss in the pump but for pressure drops due to leakage by pistons, valves and joints. The following general formula should give satisfactory results:

$$D = \sqrt{\frac{1.3\,d^2\,p}{P}}$$

where:

- p = test pressure to be placed on boiler, pounds per square inch.
- P = steam pressure on plant boiler, pounds per square inch.
- d = diameter of pump water cylinder in inches.
- D = diameter of pump steam cylinder in inches.

(2) This problem does not lend itself readily to solution by formula due to the uncertain conditions which enter into it. The only reliable method would be by actual test, reading the resulting pressure from a calibrated pressure gage.

(3) On a typical shell expansion or midship section the various strakes of plating are designated by letters, beginning at the garboard strake and lettering out around the bilge and up the side, ending with the sheer strake, thus A, B, C, etc. The letter I is generally omitted to avoid confusion. The flat keel strake, or plate, is marked F. K.

In addition to the designations just noted, some strakes are known by names which, by reason of long association with certain portions of the vessel, identify the strake immediately with those portions. The principal among the strakes so named follow together with a description of each.

Flat plate keel, a series of plates of extra thickness which forms the strake running fore and aft along the vessel's bottom at the center line.

Sheer strake, the strake of shell plating that runs along the level of the main or upper decks. Plates running along the level of the lower decks are not called sheer strakes. See "Shipbuilding Cyclopedia," page 121.

The keel and sheer strakes are important strength members because of their distance from the neutral axis of the ship. They are generally made thicker than the other strakes of side or bottom plating.

Bilge strake, a strake of outside plating running along the bilge.

Bottom strake, a strake of bottom plating lying between the garboard and bilge strakes.

Garboard strake, the strake of bottom plating adjacent to the keel. The garboard strakes are frequently made heavier than the other bottom strakes as they work closely with the keel to form the backbone of the vessel.

Topside strake, the strake next below the sheer strake.

There are other strakes which are named because of certain outstanding features or certain work done.

Doubling strake, a strake of plating fitted in conjunction with a regular strake. The sheer strake and keel are frequently doubled to provide extra strength.

Drop strake, a strake which is terminated short of the bow or stern due to the decreasing girth of the ship as the ends are approached.

Inner strake, a strake adjacent to the molded frame line.

Outside strake, a strake which laps onto the two adjacent inner strakes.

The last two terms apply to the so-called "in and out" system of plating.

(4) The dimensions of the lead stern tube are, of course, dependent upon the size of the vessel. In a wooden tug of 88 feet overall length, a hole or shaft well 8½ inches in diameter was driven through the shaft log. This was fitted with a lead sleeve or lining ¼ inch in thickness. The lead tube itself was in one piece fitted singly between the two portions of the shaft log. At its forward and after end it was expanded over the stuffing box and stern bearing, respectively.

In a smaller, higher speed boat with which the writer is familiar the bore of the shaft log is 4½ inches and the thickness of lead sleeve ⅛ inch.

(5) The following conditions are assumed:

(*a*) The piston for the cylinder in question is at the bottom of its stroke.

(*b*) The crank turns anti-clockwise when standing at the forward end of the engine looking aft.

(*c*) Steam taken over ends of valve.

(*d*) Engine has open rods, i. e., with the piston in position (*a*) the center of the ahead eccentric would be to the right of the engine vertical center line and above the horizontal shaft center line at a distance equal to the angle of advance.

(*e*) The eccentricity, or half the valve travel, equals 5 inches.

(*f*) The angle of advance or the angular distance which the center of the ahead eccentric is above the horizontal shaft center line.

(*g*) L = length of eccentric rod, i. e., center of eccentric to center of link block pin, equals 96 inches.

r = eccentricity = 5 inches.
R = half the shaft diameter (given) = 8 inches.
m = lineal movement along shaft (given) = ⅛ inch. This movement is to be forward, i. e., in the direction the shaft rotates.
ϕ = 40 degrees.
$\triangle$ = angular movement of eccentric around shaft in degrees corresponding to "m" =

$$\frac{360\,m}{2\,\pi R} = \frac{360 \times .125}{2 \times 3.1416 \times 8} = .895 \text{ degree}$$

$= 53.7$ minutes.

θ = new angle of advance = $\phi + \triangle$ = 40 degrees + 53.7 minutes.
a = vertical distance from horizontal center line of shaft to center of eccentric before movement = $r \sin \phi = 5 \times .6428 = 3.214$ inches.
a_1 = vertical distance from horizontal center line of shaft to new center of eccentric after movement = $r \sin \theta = 5 \times .6546 = 3.273$ inches.
b = horizontal distance from the vertical center line of engine to the center of the eccentric before movement = $\sqrt{r^2 - a^2} = \sqrt{(5)^2 - (3.214)^2}$ = 3.831 inches.
b_1 = horizontal distance from the vertical center line of engine to the new center of the eccentric after movement = $\sqrt{r^2 - a_1^2} = \sqrt{(5)^2 - (3.273)^2}$ = 3.78 inches.
l = vertical distance from the center of the eccentric, before movement, to center of link block pin = $\sqrt{L^2 - b^2} = \sqrt{(96)^2 - (3.831)^2} = 95.9235$ inches.
l_1 = vertical distance from new center of eccentric, after movement, to center of link block pin = $\sqrt{L^2 - b_1^2} = \sqrt{(96)^2 - (3.78)^2} = 95.9256$ inches.
d = distance which link block pin has been raised by moving the eccentric forward ⅛ inch around the surface of the shaft = $(a_1 + l_1) - (a + l)$ = $(3.273 + 95.9256) - (3.214 + 95.9235)$ = .0611 inch = 1/16 inch approximately.

This dimension "d" is also the amount which the valve is raised or, in other words, it is the amount by which the bottom steam lead would be increased. The top lead would, of course, be increased by the same amount and cut-off, admission, compression and release will all occur earlier in the stroke of the piston as a result. Had the shifting of the eccentric been in the opposite direction, the bottom steam lead would have been decreased and all events would have occurred later in the stroke.

By using the above method of procedure, the amount by which the steam lead is affected may be calculated for any movement of the eccentric on its shaft, for any diameter of shaft or throw of eccentric.

(6) There is no express rule under the Steamboat Inspection Service as to the percentage of wear down on a tail shaft. The local inspectors having original jurisdiction use their best judgment, based on practical experience.

The American Bureau of Shipping, see section 45 of the rules, provides as follows:

"Tail shafts are to be drawn for examination at least once every two years, but when liners are fitted solid in one length, the shafts need only be drawn once every three years.

"When the after bearing is worn down ¼ inch with shafts not exceeding 9 inches in diameter; 5/16 inch when over 9 inches and not exceeding 12 inches and ⅜ inch with shafts over 12 inches in diameter, the bearing is to be rebushed."

Horsepower of Multiple Cylinder Engines

Q. (1141).—Will you give some information in regard to figuring the indicated horsepower of triple expansion engines of three and four cylinders and quadruple engines, with regard to vacuum and back pressure. I refer to the difference that these will make to the mean effective pressure that is obtained from the indicator diagrams.

A. (1141).—"The term 'back pressure' is usually applied to the pressure of the exhaust from the low-pressure cylinder, although of course there is back pressure in the other cylinders due to the exhausting of the steam into the next cylinder. It is of importance to keep the back pressure in the low-pressure cylinder as low as possible, as this pressure acts on the piston in opposition to the steam pressure. In order to keep the back pressure low, care should be taken in the design of the low-pressure cylinder to make the exhaust passages and exhaust pipes of ample area and free from obstructions and abrupt turns. The back pressure in a well designed low pressure cylinder should not exceed 3 to 4 pounds absolute. It may be found from the indicator card and is usually 2 pounds more than the pressure in the condenser as shown by the vacuum gage." For the foregoing, see page 826, "Marine Engineer's Handbook," by Sterling.

Considerable attention has been paid during recent years to the design of condensing apparatus having high vacua. Bragg in "Design of Marine Engines and Auxiliaries," page 13, writes: "The effect of vacuum upon economy was investigated in certain experiments carried out by Professor Weighton. He found that the number of pounds of steam per brake horsepower was least at a vacuum of 26 to 28 inches, but that the number of heat units, working from the high pressure steam chest to the hot well per brake horsepower was least at 20 inches vacuum. While the horsepower of the engine is increased by increasing the vacuum, it causes the temperature of the hot well to be lower, and it is possible to carry the cooling to such a point that the coal per brake horsepower is increased.

"Another point brought out by these experiments was that in going from 26 inches vacuum to 28 inches vacuum, the mean referred pressure was not increased by the equivalent of 2 inches of mercury but by something less than 2 inches.

"It was also shown that the effect of increased vacuum was not confined entirely to the low pressure cylinder but reached back into the intermediate and high pressure cylinders with the result that the steam consumption instead of remaining constant per revolution increased as the vacuum increased. Both of these results are probably due to the increased range of temperature in the cylinders, causing an increase in the initial condensation. This effect would probably be greater with less stages of expansion and less with a greater number of stages."

In determining the size of a multiple cylinder engine to develop a given horsepower the size of the low pressure cylinder is first ascertained and the other characteristics fixed with this as a starting point. The "mean effective pressure" is the mean pressure of admission and expansion as derived from the indicator card or the total area of the indicator card divided by the length of stroke. The "mean referred pressure" is the mean effective pressure that would be necessary to do the combined work of all the cylinders in the low pressure cylinder alone. In the actual indicator card or diagram the lower boundary of the figure is termed the "back pressure line." The closer that this line can be brought to the zero line representing perfect vacuum the greater the area of the card and the higher the value of the mean referred pressure. A small reduction in back pressure produces an effect upon engine efficiency equal to that of a much larger increase in initial pressure. In the case of a 5,000 indicated horsepower three-cylinder triple expansion engine, the change of back pressure by one pound effected a reduction of 1 inch in the diameter of the 94-inch low pressure cylinder.

PERSONAL MENTION

Lawrence J. Brengle was appointed acting manager of the United States Salvage Association at a meeting of the directors on December 15. Mr. Brengle succeeds Charles R. Page, whose resignation took effect December 31, when he became manager of the Atlantic marine department of the Firemen's Fund Insurance Company. Mr. Brengle was formerly the underwriter of Syndicates "B" and "C" of the American Marine Insurance Syndicates in which capacity he will continue, devoting sufficient time, however, to the supervision of the administration of Syndicate "A" and of its operating agent, the United States Salvage Association, Inc. Mr. Brengle has had wide experience in the handling of the affairs of wrecked and damaged vessels and is familiar with shipping of the Pacific as well as the Atlantic coast, which fits him particularly to administer the affairs of the Salvage Association.

John H. Trowbridge, formerly with the firm of Marsh & McLennan and recently chief clerk of the American Marine Insurance Syndicates, will have direct supervision of the administration of the affairs of the United States Salvage Association, Inc., under Lawrence J. Brengle, acting manager of the association.

Thomas L. Clear, whose appointment as treasurer of the United States Shipping Board Emergency Fleet Corporation was announced in the November issue of Marine Engineering and Shipping Age (page 860), received his early training in banking and railway service. He was an assistant to General Goethals in 1908, having been appointed assistant auditor to reorganize the fiscal operations of the Panama Canal and Panama Railroad Company. In 1914 he was appointed by General Goethals as collector of the canal and later became treasurer of the Panama Railroad Company. While collector, Mr. Clear organized a plan by which ship operators were able to have ship charges paid by their local banks wherever located to a correspondent bank at the canal, greatly facilitating the movement of vessels. The system which now prevails enables an operator at any part of the world to pass his ship through the canal without any deposit and, unless the ship is in need of fuel or repairs, she is not required to stop in approaching and passing through the canal except when in the locks. Mr. Clear left the canal in the summer of 1918 and was sent to Europe by the War Department in the capacity of an inspector general, his work being confined to the supervision of financial affairs of the American Expeditionary Forces. He returned to the United States in September, 1919, and was appointed comptroller of the United States Shipping Board by Judge John Barton Payne, its chairman, but declined the appointment and, at the request of Governor Harding, returned to the Panama Canal and resumed his former position. After fifteen months' service he accepted an appointment in the United States Army as an inspector general, but resigned his commission October 7 to become treasurer of the United States Shipping Board Emergency Fleet Corporation.

Major T. L. Clear

G. O. MacConachie, in addition to his duties as assistant to Joseph W. Powell, president of the United States Shipping Board Emergency Fleet Corporation, has recently been given entire supervision of the personnel of the corporation. He was born in Detroit, Mich., and received his education at the Central High School of that city and at the University of Michigan. In 1919, he entered newspaper work and served on the staffs of various Detroit newspapers until 1914 when he entered the employ of the Campbell-Ewald Company, advertising agents. In 1917 he joined the Harlan plant at Wilmington, Del., of the Bethlehem Shipbuilding Corporation and was appointed head of the service department. During the three and a half years he was with this corporation, he supervised the general publicity work at Sparrows Point, Md., at the Harlan plant, at the Moore plant, Elizabeth, N. J., and at the Fore River plant, Quincy, Mass.

G. O. MacConachie

Charles Kerr, formerly with the Bethlehem Shipbuilding Company, has been appointed outside marine superintendent for the Main Iron Works, San Francisco, Cal.

C. A. Askew, vice-president and general manager of the Atlantic Gulf and Pacific Steamship Company, will have charge of the office affairs on the Pacific coast, succeeding Thomas J. Wade, who recently resigned.

A. P. Hammond, who has been Pacific coast manager of the Luckenbach Steamship Company for five years, recently resigned. Lewis Luckenbach will handle the affairs of the company on the Pacific coast for the present.

C. L. Christenson, for the past five years connected with the New York offices of the International Mercantile Marine Company, has been appointed manager of the Cleveland passenger office of this company which has recently been opened.

J. V. C. Comfort has been appointed manager of the Pacific Mail Steamship Company's Panama Line, according to an announcement made by Thomas Graham, vice-president and general manager. Mr. Comfort is succeeded as operating manager by Thomas James. Both these men have been with the Pacific Mail Steamship Company for many years.

Commander L. M. Stewart has been appointed successor to William Glassford in charge of the United States Naval Hydrographic office with headquarters in the Merchants Exchange Building, San Francisco, Cal. For the past few months Commander Stewart has been in charge of the eleventh destroyer division at San Diego; before this time he was captain of the destroyer *Yarnall* with the Asiatic Squadron. During the war he commanded the destroyer *MacKall* and was also in charge of the mine assembling base at Inverness on the coast of Scotland.

Shipping and Ship Operation News

Changes in Steamship Routes — Passenger and Freight Activities—Port Plans and Other Notes of General Interest

Chartering of Tankers Profitable To Shipping Board; Bare Boat Plan Returns $50,000 a Month Revenue

J. Barstow Smull, Vice-President of Emergency Fleet Corporation, Reports on Six Months' Activities—Losses in Voyage Operations Being Steadily Diminished

J. BARSTOW SMULL, vice-president of the United States Shipping Board Emergency Fleet Corporation, in charge of allocations and charters, has issued the following statement regarding the work accomplished in his division in the past six months:

"I found on assuming my office in July that there was no one in the whole organization who knew anything about chartering. Charters were being put through that were absolutely detrimental to the Board's interests. I selected the best man I could find in the chartering trade to take over this most important work and stationed him in New York. Since then we really have had few slip-ups whereby the Board suffered.

"The chartering of tank boats has been very profitable and is still going on today. Of course, the general trades have been so poor that it has not paid to charter vessels and I have not chartered any vessel for general cargo business.

"We have been struggling hard with the bare boat charter as the times have been against us, but we are most pleased to say that we have twenty-three (23) vessels under bare boat charter which turn in a revenue of about $50,000 a month. With an improvement in the freight market at all, undoubtedly we will have the opportunity of putting forward quite a few boats on time charter basis."

Discussing the charter situation on the Atlantic Coast, Mr. Smull continued:

"Some time ago the Board of Trustees decided that it was not fair to privately owned tonnage on our Atlantic Coast to charter our vessels on a bare boat basis to compete against established lines in the coastwise trade. There is no doubt that a ship on a bare boat charter at 50 cents a ton can very successfully compete with privately owned tonnage bought at high prices, for the private owner has to take into consideration in making his rates, his overhead expenses, his depreciation, interest on his money and Marine Insurance.

"We are mandated by the Jones Bill not to interfere with privately owned established trades, and in following out the requirements of the Merchant Marine Act it is necessary for us to refrain from chartering our vessels on any sort of a time charter basis where they would be thrown in competition with those vessels privately owned."

The vice-president then briefly reviewed the activities of the Contract Department in his division:

"This department has charge of the working out of all charter parties and contracts effected on Shipping Board tonnage.

"It might be interesting to the public to know that since the Board has been in office we have been able to collect more than $178,000 in demurrage. Formerly these demurrage claims either laid dormant or were put into the hands of the legal department, where it would take anywhere from three to five years to get them tried out in the courts.

"We have been able to settle these cases either by mutual agreement or by arbitration. My department at present has under active negotiation for settlement more than $300,000 worth of these claims. Altogether there seems to be about $2,000,000 of these demurrage claims against American shippers, and about $3,000,000 against foreign governments which will have our attention in due course."

Regarding withdrawals and allocations, Mr. Smull said:

"On July 24 there were 75 active managing agents of the Fleet Corporation operating 674 steel ships. Of this number of agents there were 12 acting as tramp operators, having a total of 125 vessels in service. The losses were running from $5,000 to $25,000 per round trip voyage to Europe, approximately $1,250,000 being the loss in voyage operations last June.

"On January 1, 1922, there will only be 43 active agents handling 321 ships. All tramp steamers have been withdrawn. The losses in voyage operations in October, which is the last month for which we have a report, had been cut to $400,000, and they are still being diminished.

"From July 20 to the present date 526 steel cargo carriers have been withdrawn from service, and 173 are allocated as follows: Eighty for berth service, 13 for bulk cargoes, and 80 as substitutes for the betterment of services and the saving of repairs. This leaves a net number of 353 steel cargo and passenger vessels that were tied up from July 20 to date."

FREIGHTER POPULAR

West Lewark Clips 11 Days from Foreign Voyage Schedule

When the *West Lewark* was delivered to the United States Shipping Board by her builders, the Los Angeles Shipbuilding & Dry Dock Company, last July, and was chartered by Williams Dimond & Company for Pacific-European trade, she attracted considerable attention at northern ports because of her being the first Pacific coast built vessel of her type and one likely to prove particularly popular with shippers.

The *West Lewark* left the west coast at the end of August with full cargo for Glasgow, Liverpool, London, Antwerp, Rotterdam and other ports. According to the schedule laid out for her she should have returned to Los Angeles harbor November 14. She reached here, however, Friday, November 11, and by Saturday, November 12, she had unloaded her cargo at this port and had again cleared for northern ports. Not only this, but while in Europe she had been diverted to Liverpool for return cargo, thus taking up eight days not allowed for her schedule. Captain Ansell, therefore, claims to have clipped his schedule eleven days and to have brought his ship back after traveling 20,000 miles without a stop, and in that perfect condition which reflects the utmost credit upon the port of her registry and the work of the organization that built her.

With full cargo the *West Lewark* averaged 11.95 miles per hour in the run from Cristobal to Glasgow. Her revolutions were 75.6, and her average oil consumption was .99 barrels per mile.

World's Largest Steamship to Sail from New York on May 20

Following the return from abroad of P. A. S. Franklin, president of the International Mercantile Marine Company, the White Star Line has announced that the 35,000 ton *Homeric* will make her first return voyage from New York on March 1, 1922, and that the 56,000 ton *Majestic*, the world's largest steamship, will make her first voyage out of New York on May 20. These two steamers, with the *Olympic*, will maintain a regular weekly service between New York and Southampton via Cherbourg.

The addition of the *Majestic* and *Homeric* to the Southampton service releases the *Adriatic* for the New York-Liverpool service, where she will operate with the *Celtic*, *Cedric* and *Baltic* in a regular weekly schedule. These four steamers, in addition to passenger accommodations, have an unusually large cargo capacity.

Plans Maturing for New Direct Steamship Line Between the Hawaiian Islands and Los Angeles, Cal.

Steamers Aeolus and Huron Allocated to Los Angeles Steamship Company for Expansion of Service to Include Passenger and Freight Route to the Islands

PLANS for the establishment of a direct steamship line between the Hawaiian Islands and Los Angeles have been under development for several weeks past. Announcement of these plans was made following the launching, at the plant of the Los Angeles Shipbuilding & Dry Dock Company, of the *West Chopaka,* 35th and last steel freighter built by this concern for the United States Shipping Board and now under charter to Struthers & Barry.

Following the launching of the *West Chopaka,* Fred L. Baker and Erle M. Leaf, respectively president and vice-president of the shipbuilding company, entertained some three hundred guests on the steamship *Harvard,* taking them over to Catalina. Among the guests were men representing most of the important civic and business interests of Los Angeles. At a meeting held in the smoking room of the *Harvard* the plan to expand the interests of the Los Angeles Steamship Company and include a high class freight and passenger service with the Hawaiian Islands was fully discussed. Shortly after this meeting Mr. Leaf went east, and placed before the Shipping Board and administration officials the definite plans of his associates, requesting the allocation by the United States Shipping Board of two ex-German liners.

December 1st, despatches from Washington announced the success of Mr. Leaf's errand and the allocation to the Los Angeles Steamship Company of the *Aeolus* and *Huron,* now being operated by the Munson Line on the South American run, but shortly to be turned back to the Shipping Board and through them to be delivered to the Los Angeles people early in 1922.

The *Aeolus* and *Huron* are 15-knot, oil burning vessels, originally in the Atlantic service between Bremen and New York, and then known as the *Grosser Kurfurst* and the *Frederich der Grosse.*

The *Aeolus* is 560 feet long between perpendiculars, and the *Huron* is 528 feet. Each has capacity for about 400 passengers, and each is equipped with gyroscope, being therefore considered as exceptionally steady and claimed to be great favorites with the sea-going public.

Certain changes and improvements planned for these vessels by the Los Angeles Steamship Company will be made upon their arrival at Los Angeles harbor, but it is understood that having but recently been thoroughly re-conditioned, decorated and furnished, the contemplated re-equipment and alterations will not take long, so that the new service to Honolulu is expected to be started during the coming spring.

The importance of this service to the Hawaiian Islands and to the entire Los Angeles community cannot be well overestimated. A "home owned" line of ships, recognized as being of the very finest class, is of paramount importance to any port. It means business for the port out of all proportion to that which comes from vessels merely "calling" at the port. To the Hawaiian Islands it means greater benefits since this direct service will be of incalculable advantage in developing tourist travel as well as providing a sure and regular service for every day business between these two points. Instead of being, as it is today, mainly a point of call between California and the Orient, Honolulu will be a terminal port of regular service of the highest class with Los Angeles and that vast tourist travel which Southern California has built up.

In the course of his negotiations in the East, Mr. Leaf had the honor of an interview with President Harding, who expressed himself as being particularly interested in the development of plans which would further the interests of the Islands and place them in closer touch with the Pacific Coast.

"NO. 80" ENTERTAINS

Ocean Engineers Greet Santa Claus—President Martien Re-elected

A very successful Christmas smoker and general "get together" meeting of Ocean Marine Engineers Beneficial Association, No. 80, of New York city, was held in their club rooms at 15 Whitehall Street, on Tuesday night, December 20, 1921. The affair was formally opened by the introduction to the assembled members and their guests, which numbered about 450, of Mr. E. Martien, the president of the local. The introduction was made by Mr. B. L. Todd, better known among the boys as "our Bert," the business manager.

The entertainment consisted of many musical numbers rendered by accomplished musicians and fellow members, story telling by George Smith, several very good three-round bouts, a visit from Santa Claus and refreshments. The speaker of the evening was the Honorable Peter J. Brady, Commissioner of Records, of the city of New York, and an official of the Printers' Union, who gave a very interesting account of the trials that the several labor organizations had gone through during the past year of depression, but left all with the impression that the "worst was over."

Stephen J. Kelly, president of Allied Printers, State of New York, sang several ballads, and Mr. Todd announced that Mr. Martien had consented to be president for the coming year.

STEAMSHIP INTERESTS

According to officials of the Mallory Steamship Company, a new ten-day steamship service between Tampa and New York will be inaugurated with the sailing of the Mallory steamer *Altamaha.* The company proposes to use its own boats in this service and to release the boats of the Shipping Board which have been in use by the line since the war.

The Robert Dollar Steamship Company will inaugurate a freight service between Seattle, Vancouver, B. C., and San Francisco, on the Pacific Coast and ports of the Far East, on January 10, 1922, according to an announcement made public by officials of the company. The three ships to be used in this service are the *Harold Dollar, Bessie Dollar,* and *Melville Dollar.*

The tanker H. M. Storey has had its trial trip under the supervision of Captain Herbert Kirst, of the Bethlehem Shipbuilding Corporation, San Francisco, Cal. She is the second of three tankers to be completed by the Bethlehem Company for the Standard Oil Company. All three are of the same type and of 15,000 deadweight tons each, with a carrying capacity of 120,000 barrels of oil and a speed of 11 knots.

Following the disbanding of the firm of Struthers & Dixon, and the closing of their Seattle and San Francisco offices, C. S. Holmes, former resident agent for the firm at Seattle, has announced the formation of the C. S. Holmes Shipping Company of Seattle, with offices at 321 L. C. Smith Building, Seattle, Wash. The new firm will be agent at Seattle for the Intercoastal Sea Carriers, Inc.

It is announced that the State Railroad Commission, San Francisco, Cal., has authorized the Bay Transportation Company to issue not exceeding $127,500 of its common stock and to assume the payment of indebtedness amounting to $207,562.93. The Bay Transportation Company was recently organized for the purpose of taking over the business of E. V. Rideout & Company. The company operates steamers and barges in San Francisco Bay.

Indicative of better shipping activity at Philadelphia, it is announced that two new services will be established from the port of Philadelphia by the Hudson Shipping Company. The Export Steamship Corporation, 25 Broadway, New York, will inaugurate a line to Constantinople, Smyra, and Alexandria with the freight steamer *Blair,* and the Baltimore Steamship Company, Inc., will inaugurate the second service with the steamer *Coelleda.* Reductions in class and commodity rates between Norfolk and Boston and Providence have been put into effect by the Merchants & Miners Transportation Company. New rates on fruit and vegetables are from 5 to 10 per cent lower than those hitherto in force, and oyster rates are a little more than 5 per cent lower than formerly. Rates on northbound forest products, knit goods, and peanuts are also revised downward. Southbound rates on iron and steel products have been cut.

A reduction of $21.50 in third class passenger rates to Hamburg and $28.50 to

Shipbuilding and Terminal Development

What the Shipyards Are Doing—Dry Dock Notes—Launchings—New Engineering Projects

City Island, N. Y., Shipyard Gets Contract To Build Distinctive Type Of Houseboat Having Oil Engines

Plans and Specifications Prepared by Henry J. Gielow, New York Naval Architect, Provide for Capable Seagoing Craft Also Suitable for Florida Waters

AT the yard of Kyle & Purdy, City Island, N. Y., work has been commenced on the construction of a steel houseboat for Mr. Louis H. Eisenlohr, of Philadelphia, member of the Philadelphia, Corinthian and other eastern yacht clubs. Plans and specifications for this yacht were prepared by Henry J. Gielow, the veteran naval architect of this city, and will be a notable addition to the houseboat fleet. This craft will have the distinction of being one of the first houseboats equipped with heavy oil engines of the Diesel type.

The principal dimensions will be: Length over all 100 feet 9 inches; length on load water line 95 feet 3 inches; beam, moulded, 21 feet; and draught 4 feet 6 inches when fully loaded. The dimensions of this yacht have been determined with a view to securing a thoroughly sea-going vessel, and at the same time obtaining a craft well suited for cruising in the lagoons, streams and inland bays of Florida.

The hull will be constructed of mild steel, the side plating being carried up to the upper deck, with steel deck beams and diagonal strapping, thus securing a thoroughly substantial construction. Her lines will be the combined perfection of sea-going qualities with a minimum draught, and were it not for the rectangular windows, would show all the characteristics of a sea-going motor yacht. These windows, however, add so much to the owner's comforts, both as to light and ventilation, that it was considered best to use them instead of the much smaller, conventional circular air ports.

The deck house will be 44 feet long, with a mean width of 14 feet in the clear, constructed of mahogany panel work. In the forward end will be the dining room 15 feet 6 inches long by 14 feet wide, fitted with buffet and sideboard, china closet, serving tables, etc. The pantry has a floor space of 74 square feet, fitted with dressers, sink, dish racks, china closet; refrigerator and a dumbwaiter to galley below. Aft of dining room, on port side will be a lavatory, and opposite starboard side a cabinet with racks for guns, fishing tackle, ammunition and sporting supplies. Next will be the main saloon or social hall, 18 feet long in the clear and occupying the full width of the deck house, with stairway in the after end leading to staterooms below; among the furnishings will be a desk, book case, piano, divan, etc.

The owner's and guests' quarters will be in the after end of the vessel, and will occupy the entire width for a fore and aft distance of 38 feet. The owner's stateroom will be forward, and have a floor space of 200 square feet, fitted with brass bed, chiffonier, bureau, mirrors and large wardrobe. Forward of this stateroom will be a bath room, connected with the owner's stateroom. Aft of the owner's room will be four more staterooms and two more bathrooms, each stateroom furnished with bed, bureau, and wardrobe, and all bath rooms will have porcelain enameled lavatories, bath tubs, etc., with nickel-plated mountings, open plumbing, and tiled floors and walls.

The machinery space will come next and occupy the full width of the vessel for a distance of 18 feet fore and aft. Next forward comes the galley with a floor space of 130 square feet, fitted with range, dish racks, dressers, lockers, sinks, cold storage, etc.

Forward of this will be the officer's and crew's quarters, all designed on a liberal scale, occupying a floor space of 468 square feet; in fact, the aim in designing this vessel has been to secure fewer large roomy accommodations rather than a larger number of smaller, cramped ones. Liberal accommodations for storage of ice have been provided; but a mechanical refrigerator plant will also be installed. The interior finish will be white pine panel work finished in ivory white, with mahogany trim finished bright.

The propelling machinery will consist of two 120 H. P. six cylinder heavy oil engines of the Diesel type, which gives the vessel a speed of over 12 statute miles per hour. The oil tanks have a capacity of 3,400 gallons, which will give a cruising radius of 2,500 miles at full speed, which is unusually large for a vessel of this type. The propellers are to be of manganese bronze, especially designed for this vessel by Mr. Gielow.

Fresh water tanks are to be provided with ample capacity to last for a cruise of three thousand miles.

Motorship Missourian Launched at Chester, Pa., for American-Hawaiian Line

The 11,000 deadweight ton motor ship, *Missourian,* built for the American-Hawaiian Steamship Company, was successfully launched Wednesday, December 14, 1921, at the Merchant Shipbuilding Corporation's yard, Chester, Pa. This is the second twin screw motor ship, and all American product to be launched on the Delaware River.

The principal dimensions of the *Missourian* are as follows: Length overall, 461 feet; moulded beam, 59 feet 8 inches; moulded depth to shelter deck, 39 feet; cargo capacity, 560,000 cubic feet; contract speed, 11½ knots.

The propelling machinery consists of two Burmeister & Wain six-cylinder, single-acting, four-cycle Diesel engines of the cross-head type. Each engine is rated at 2,250 Diesel indicated horsepower.

Both main and auxiliary Diesel engine sets are nearing completion in the shops of William Cramp & Sons' Ship and Engine Building Company, Philadelphia.

Contract Awarded to George B. Spearin & Co. for New Pier at 44th Street, N. R.

The George B. Spearin & Company, Inc., 90 West Street, New York, with a price of $363,565, was awarded the contract for the construction of a new pier at 44th Street, North River, following the opening of tenders by the Department of Docks, Pier A, North River, New York, on Monday, December 12.

The present pier with its freight shed is to be entirely removed and also the bulkhead shed which extends across the inner end of the pier. The engineer's estimate of the amount of dredging to be done is about 5,400 cubic yards. The pier is to be supported on vertical piles and braced with inclined piles. The superstructure will consist of double rangers over the outer bay and of side and shed rangers, chocking, mooring posts, single bitts, fendering and fender piles, a concrete deck, except wooden decking over the outshore of bay. Four elevator pits are to be constructed and fire walls are to be built beneath the pier across its full width. For the work inshore of the bulkhead line the contract comprises all pier construction including retaining walls, pile and timber work, sheet piling, concrete foundations, concrete deck, etc. It is estimated that about 3,000 cubic yards of riprap will be used to secure greater stability around the piles.

The time allowed for completion is 275 days.

$43,000,000 Recommended For Government Port and River Work During Fiscal Year 1922-23

Substantial Sums Requested by Chief of Army Engineers for Development of Principal Harbors on Atlantic and Pacific Seaboards

MAJOR GENERAL BEACH, Chief of Army Engineers, in his annual report to the Secretary of War, Washington, D. C., recommends a total expenditure of approximately $43,000,000 for river and harbor improvements during the fiscal year 1922-23, exclusive of the proposed $7,500,000 project for Muscle Shoals, Ala. Among the principal harbor projects are the following:

New York, $2,900,000 including $2,200,000 for the East River and $350,000 for the Hudson River Channel; Philadelphia to the sea, $3,660,000 including $500,000 for Philadelphia Harbor and $1,500,000 for Liston Range; Savannah, Ga., $1,025,000; Norfolk, $500,000; Los Angeles, $300,000; Humbold, Cal., $400,000; and Grays Harbor and Bar Entrance, Wash., $660,000.

Principal river projects: Mississippi from the mouth of the Ohio to the mouth of the Missouri, $1,000,000; from the mouth of the Missouri to Minneapolis, $2,000,000; Southwest Pass, $1,136,000, and South Pass Channel, $250,000; Ohio for locks and dams, $5,000,000 and for general open channel work, $534,000; Allegheny Locks and dams, $900,000, and open channel work, $5,000; Detroit, $1,100,000; Illinois below Copreas Creek, $440,000; Columbia and lower Willamette below Vancouver and Portland, Ore., $850,000; Missouri, $145,000 including $25,000 from Kansas City to Sioux City and $20,000 from Sioux City to Fort Benton, Montana, and St. Marys River, Mich., $557,000.

Remarkable Feat Accomplished In Salvaging and Docking the 12,000 Ton Standard Oil Tanker F. D. Asche

ONE of the most remarkable salvage operations on record was performed when the *F. D. Asche*, a Standard Oil tanker, arrived in New York recently, after being towed all the way from the Bahamas with practically no bottom in her. The *Asche*, in command of Captain L. S. McKenzie, was caught in the cyclone that devastated Tampa, swept out of her course and piled up on Stranger Key reef. In the next twenty-four hours the *Asche* was carried one mile over the reefs where she remained fast.

The wrecking steamers *I. J. Merritt* and *Willard*, of the Merritt-Chapman Wrecking Company, were sent to the assistance of the *Asche*. It was found by the divers that the hull of the *Asche*, with the exception of the bottom, had remained intact and that the oil carrier was susceptible therefore to being raised by means of compressed air tanks.

After being raised and still kept afloat by the emergency compressed-air tanks, the two wrecking steamers took the *Asche* in tow and brought her safely to New York, where she was docked in the graving dock of the Robins Dry Dock and Repair Company of the Todd Shipyards Corporation. The docking of this vessel with only the information furnished by divers as to where and how high the supporting blocks should be placed was also an engineering feat.

The accompanying photograph was taken after the *Asche* was dry docked. The bottom from the bow to the stern is one continuous wave with an amplitude of four to eight feet. Undoubtedly the Isherwood system of longitudinal framing permitted the bottom to take a wave formation without breaking, as transverse frames would have presented too many hard spots. At any rate, this system of framing has localized the repairs to the portion damaged. That is, an entire new bottom to a point between eight and ten feet above the keel will have to be fitted, but the sides above this point are in good condition.

The F. D. Asche in Dock, Showing Crumpled and Torn Plates

CONVERSION COMPLETED

Aircraft Carrier Wright Turned Over to Navy Department

The Todd Shipyards Corporation has turned over to the United States Navy the U. S. S. *Wright*, which has been converted into a balloon and seaplane mother ship The vessel is named in memory of Wilbur Wright.

The conversion of this vessel, originally built for the transport service, was carried out at the Tietjen & Lang plant in Hoboken, N. J. It included additions, changes and alterations that would provide for the stowage of six kite balloons for the inflation and housing of kite balloons aft in a balloon well, for the necessary hydrogen generating plant for balloon inflation, for hydrogen stowage and for efficient repair plants for balloons and seaplanes.

The vessel has been arranged for flying operations of kite balloons and as a tender for seaplanes, carrying spare wings and other spare parts. A pigeon coop, aerological laboratory and a complete photographic laboratory have been provided.

A hydrogen generator of large capacity, constructed to use salt water for cooling, a number of hydrogen compressors, a number of hydrogen flasks and an air blower for the kite balloons and two balloon winches will be installed for use in the flying operations and the inflation of balloons.

The repair facilities consist of wire assembly shop, tool issuing room, blacksmith, foundry, sheet metal and coppersmith shop; carpenter and pattern shop, machine shop and motor erecting shop, electrical work shop, fabric and dope shop. Two balloon winches are being fitted for use in flying operations of balloons. A large space forward is provided for wing section stowage, and a large hatch in the weather deck for the purpose of getting the wing sections below. Space will also be available for the stowage of spare parts for kite balloons and seaplanes.

The battery will include four 5-inch 51 caliber guns, two forward and two aft.

Marine Construction News of the Month

Ship Contracts — New Ship Concerns and Shipyard Improvements—Terminal Projects—Government Contracts

SHIPS AND SHIPBUILDING

Reconditioning Job.—The firm of Theodore Crane & Sons, Brooklyn, N. Y., with a price of $44,875 and twenty-five days, were low bidders for the reconditioning of the United Fruit Company steamship Tanamo, bids for which were opened December 7. The highest bid for the job, submitted by the Atlantic Basin Company, amounted to $83,486 and sixty days.

To Convert Steamer, Hoboken, N. J.—The W. & A. Fletcher Company has been awarded the contract for reconditioning the steamship Lake Fackler, operated by the Clyde Line, bids for which were opened by the Shipping Board on December 5. The vessel is to be converted into a fruit carrier and the specifications called for the providing of eight cargo ports, sheathing of the 'tween decks with planking, the putting up of banana bins, the installation of sixteen ventilators and various other detail work. The Fletcher price was $10,327.

Dredge to Be Overhauled, Shooters Island, N. Y.—The Standard Shipbuilding Corporation, with a bid of $28,000, was awarded the contract for the extensive overhauling of the Municipal dredge Grabit, of the Department of Docks, Pier A, North River, New York.

Large Repair Job, Hoboken, N. J.—The United Fruit Company's steamship Heredia is at the yards of the W. & A. Fletcher Company for extensive repairs, which will probably cost close to $100,000.

Steamer Conversion.—The Bethlehem Shipbuilding Corporation, Ltd., was low bidder for the job of reconditioning the Munson Line steamship Walter D. Munson, bids for which were opened at the Munson Line office in New York on December 6. The Bethlehem Company's bids were (a) $288,500 and 120 days, and (b) $237,680 and 90 days. The ship may be converted into a combination passenger and freighter with accommodations for about 175 passengers. Proposition "A" provided for the building of a shelter deck over the well deck and proposition "B" called for the building up of the superstructure in order to meet the requirements of the specifications.

Reconditioning Contract, New York.—Bids for reconditioning the transport Northern Pacific for passenger service were opened at 3 p. m., on December 15, at the office of the Robert Dollar Steamship Company, 11 Moore street, New York City. It is understood that the award of the contract rests principally between the Sun Shipbuilding Company and the W. & A. Fletcher Company. The prices submitted were as follows: Sun Shipbuilding Co., $335,460, 110 days; Newport News Shipbuilding Co., $401,800, 90 days; Robins Dry Dock & Repair Co., $421,000, 95 days; W. & A. Fletcher Co., $424,710, 85 days; Morse Dry Dock & Repair Co., $550,000, 120 days; Wm. Cramp & Sons Ship and Eng. Bld. Co., $550,000, 240 days; Bethlehem Shipbuilding Corp., $698,000, 140 days.

Steamer Repairs, Brooklyn, N. Y.—The Tebo Yacht Basin, of the Todd Shipyards Corporation, was awarded the contract for repairs to the steamship Bessie Dollar at the opening of bids on Monday, December 12. The price was $1,495.

Barge Wanted, Brooklyn, N. Y.—The United Machine Works, Thomas Jefferson Building, is in the market for the purchase of a barge operated by steam, having a stern paddle wheel, similar to steamers used on the Mississippi river.

Vessel Damaged by Fire, Boston, Mass.—The British steamship Amasis, which arrived at Boston on December 3 from Alexandria with 15,000 bales of cotton, was afire at her pier. Damage sustained is estimated at $45,000.

May Build Schooner, Baltimore, Md.—It is reported that a Cuban representative of business interests in that island was in the city of Baltimore interviewing shipbuilding companies as to the cost of a prospective schooner to be built of steel.

Derrick Boat, Pittsburgh, Pa.—The United States Engineer, Custom House, Nashville, Tenn., has let a contract to the Dravo Contracting Company, Diamond Bank Building, for the construction of a derrick boat at a price of $11,785.

Want Wooden Hulls for Lighters, Portland, Ore.—The Shipping Board is considering the bid of the Port of Portland for four wooden hulls moored in that port. If the bid is accepted, the city proposes to use the hulls for lighters.

To Acquire Steamers, San Pedro, Cal.—It is reported that a statement by Earl M. Leaf, vice-president of the Los Angeles Steamship Company, is to the effect that his company may buy five steamers from the United States Shipping Board which they would have converted into passenger and cargo steamers for the Oriental trade.

Extensive Repairs, Chicago, Ill.—After having been tied up at Philadelphia for about five years, the former Clyde Line steamer George W. Clyde has left for Chicago with a cargo. The vessel will be extensively reconditioned and will be added to the Lake Michigan fleet of the Chicago Steamship Company.

Propeller Contract Award, New York.—The Ferguson-Herbert Corporation, 95 Liberty street, builders of semi-steel, steel and bronze propellers, has been awarded a continuous contract for the supply of propellers for the tugs and Sound steamers of the New England Steamship Company. The Ferguson-Herbert Corporation has similar contracts with a number of railroad, ferry and towing lines in New York harbor.

Boat Contract Awarded, Oakland, Cal.—It is announced from San Francisco that the Pacific Boat Company has been awarded the contract for a new dispatch and towing boat for use about San Francisco Bay, the price being $10,759.

Mechanical Burners, New York.—The Todd Shipyards Corporation has received an order for thirty Todd mechanical burners made by the White Fuel Oil Engineering Company for installation on the Canadian-Pacific Ocean service steamship Montclare, which is now building on the Clyde Bank. This means that the ship will be fully equipped with an American burner system.

To Recondition Steamer, New York.—It is reported that the steamship New York, which was recently sold at a marshal's sale, is to be reconditioned immediately and placed in the Reval-Danzig service as a sister ship to the steamer Gdansk. The vessel will have the same operating and passenger agents as the Gdansk.

Steamship Repairs, Sparrows Point, Md.—The United States Shipping Board has awarded the contract for docking and repairing the steamer Eastern Temple to the Bethlehem Shipbuilding Corporation on a bid of $4,915, and the contract for repairs to the West Lashaway to the H. E. Crook Company at a price of $1,543.

Repair Contract Awards, Hoboken, N. J.—The contracts for repairs to the Tide Water Oil Company steamer Robert H. Hopkins and the Hudson Day Line steamer Hendrick Hudson and the Army transport Wheaton have been awarded to the W. & A. Fletcher Company. The total amount involved will probably be close to $16,500.

Vessel to Be Overhauled, New York.—It is reported that the passenger and freight steamer Argentina, which has just been purchased by the Luckenbach Steamship Company at a price of less than $25 per ton, will be overhauled in New York at a cost of approximately $50,000. She is a vessel of 10,000 tons, and her present passenger accommodations will be taken out in order to fit the ship for the company's intercoastal service.

Service Boat, San Pedro, Cal.—Work is being pushed at the plant of the Los Angeles Shipbuilding & Dry Dock Company on the construction of a combination oil, water, and service boat which, when completed, will be operated by the company to serve shipping in Los Angeles harbor. The boat will be of steel, 88 feet long with 484 tons of oil tank capacity. She is to be equipped also with water tanks and can be used for the transportation of deck loads of lumber or varied cargo.

Reconditioning Contract Award, Seattle, Wash.—The contract for reconditioning the steel steamship Starr, of the San Juan Fishing & Packing Company, has been awarded to the Seattle Shipbuilding & Dry Dock Company, the job to cost about $15,000.

Schooner Repairs, San Francisco, Cal.—The Union plant of the Bethlehem Shipbuilding Corporation was low bidder at a price of $20,996, for repairs to the steam schooner Thomas Crowley, which was recently taken off the rocks near Point Concepcion. Other tenders submitted were Hanlon Dry Dock, $29,160; Moore Shipbuilding, $43,465; Barnes & Tibbitts, $44,098; United Engineering Company, $48,311, and Benjamin Dallerup & Son, $52,800.

To Build Icebreaker, Montreal, Canada.—The contract for the construction of the Canadian Government icebreaker to be used on the St. Lawrence River has been awarded to Canadian Vickers, Ltd., this company being the lowest bidder at a price of $1,580,000. Other bids included the Wallace Shipbuilding Company, Vancouver, $1,872,000; J. Coughlan & Sons, Vancouver, $1,800,000; and the Halifax Shipyards, Halifax, $1,750,000.

May Purchase Freighters, Vancouver, B. C.—It is reported that the Canadian Robert Dollar Company will purchase two large freighters early in 1922, to be added to their present fleet. One of the vessels will be put on the round-the-world service maintained by the Dollar Company, and the other on the Vancouver-Orient Line, thus permitting a thirty-day Oriental schedule.

Lightship Launched, Morris Heights, N. Y.—The steam lightship No. 105 being constructed at the plant of the Consolidated Shipbuilding Corporation for the Baltimore lighthouse district has just been launched, and as soon as ready will be brought to Baltimore to be fitted for service. The new vessel, which is an oil burner, is intended to replace the lightship sunk off Diamond Shoals by a German submarine during the war.

Three New Passenger Liners to Be Built, San Francisco, Cal.—According to latest reports bids have been asked for the construction of three new passenger liners for the coastwise service of the San Francisco & Portland Steamship Company. The company has only one vessel operating between San Francisco and Portland at present and is anxious to put in commission more vessels in order to help out the Rose City, and to replace the steamer Bear, which was lost, and the Beaver, which was taken over by the Government during the war. It is said that the new steamers will be similar to the Bear and Beaver, but will be along more modern lines, to have greater speed and more beam. Passenger accommodations will embody the most modern facilities. The ships will also have a large cargo carrying capacity.

Shipbuilding Activities at Port Arthur, Ont.—It is reported that the plant of the Port Arthur Shipbuilding Company will remain open all winter, giving steady employment to a large number of men. They are doing a great deal of dry docking and extensive repairing on lake steamers and tugs. The steamer Huronton, which is an American boat recently purchased by the Matthews Steamship Company, of Toronto, is to undergo extensive repairs, and will probably remain at the yard all winter. In addition to the general repairs a complete set of new boilers will be installed, the boilers to be de-

signed, built and erected at the Port Arthur Shipbuilding Company's plant. The company has on hand orders for two large boilers for the western market, as well as for low pressure heaters of varying sizes, which will be built during the winter. The company will also build on speculation about twenty low pressure boilers of various sizes, which will be placed on the market. They are also said to be negotiating for the contract to build a big bulk lake freighter in the near future.

Dumper and Scow Repair Bids, Brooklyn, N. Y.—At the opening of bids by the Department of Street Cleaning, Ira Bushey & Son, Brooklyn, N. Y., was low bidder for repairs to dumper No. 8 and the National Dry Dock Company was low bidder for repairs to scow No. 12.

Boat Surveys, New York.—It was learned today that the Department of Plant and Structures is conducting a survey of the nine boats of the Union Ferries, preparatory to taking over these lines, and the Board of Estimate has authorized the institution of condemnation proceedings for the Brooklyn terminals. Plans and specifications for the three electric drive ferries for service to Staten Island are almost completed.

Coastwise Vessel.—Plans and specifications for an 18-knot coastwise, Diesel engined passenger ship have been prepared by Robert W. Bruce, naval architect, Washington, D. C. Mr. Bruce stated that the identity of the owners is confidential at this time. The vessel will carry 150 first class and 50 steerage passengers. The propelling machinery will have 6,000 horsepower.

Alteration Contract Placed, New York.—The New York Harbor Dry Dock Company, with a price of $41,361, was awarded the contract for the installation of a steam heating system in the lower 'tween decks and the putting in of fruit carrying equipment in the Shipping Board steamers, Lake Fillmore, Pulwico, Vinton County and Lake Faristol at the opening of tenders by the Shipping Board at 45 Broadway, on December 12.

Derricks, Nashville, Tenn.—The District Engineer, United States Engineer Office, Post Office Box 900, Nashville, Tenn., will receive bids until 11 a. m., January 16, 1922, for the construction of three steel derricks. The derricks are to be of the stiff leg type and all parts are to be designed to safely withstand the maximum stresses resulting from the following conditions: dredging with an 8,500 pound 1½ cubic yard orange peel bucket with the long boom at 10 degrees with the horizontal or 20-ton live load on short boom at 35 degrees with horizontal and straight-ahead. Engines with a rating of about 12,000 pounds pull are to be used on the boats. The vertical height from deck to the top of A-frame is to be not more than 46 feet, the bull wheel shall be of structural steel or structural steel and steel castings and shall be 16 feet in diameter. All three outfits are to be delivered f. o. b. Fox Bluff, Tenn., a station on the Tennessee Central Railroad about 40 miles from Nashville, Tenn. Both of the 74 by 34 foot derrick boat hulls will be in place to receive the derrick equipment by the time the award is made, but the 76 by 34 foot hull just contracted for will not be delivered until May, 1922.

Boiler Contract Bids, Memphis, Tenn.—Bids for furnishing and delivering two watertube boilers for the United States dredge Beta and three watertube boilers for United States dredge Henry Flad were opened at 3:30 p. m., November 16, at the office of Colonel L. A. Rand, Corps of Engineers, Mississippi River dredging district. The Charles Ward Engineering Works, Charleston, W. Va., with a price of $18,750, was recommended for awarding of the contract for three boilers for the Henry Flad and the Babcock & Wilcox Company, Cincinnati, Ohio, and New York, with a price of $14,353, was recommended for awarding of the contract for two boilers for the Beta.

Packet Boats, New York City.—Plans and specifications for five new packets to ply between New York and Buffalo are under way by R. R. Livingston, Marine Engineer, of 2 Rector street, according to official information obtained by Marine Engineering and Shipping Age. The boats will be equipped with Diesel electric drive and it is believed the total cost will be close to half a million dollars. Preliminary figures place the length of the packets at about 160 feet with a carrying capacity of 500 tons each. There will be two Diesel engines, driving generators, and two motors, driving twin propellers. The power plant of each boat will develop about 260 horsepower. It is understood that the five boats are to be completed by May, 1922.

CONSTRUCTION FOR NAVY

Vessels under construction for United States Navy and their degree of completion as reported November 30, 1921, by the Bureau of Construction and Repair, Washington, D. C., are as follows:

Type Number and Name	Contractor	% of Completion Dec. 1, 1921 Total
BATTLESHIPS (BB)		
45 Colorado	New York S. B. Corpn.	84.9
47 Washington	New York S. B Corpn.	69.8
48 West Virginia	Newport News S. B. & D. D. Co.	65.7
49 South Dakota	New York Navy Yard	36.5

Returns for Construction Job, Pittsburgh, Pa.—Abstract of proposals for furnishing and delivering six steel dump scows, received in response to advertisement and specifications dated October 24, 1921, and opened at U. S. Engineer Office, Pittsburgh, November 23, 1921:

Nashville Bridge Co., Nashville, Tenn.	$104,340
Charles Ward Engineering Works, Charleston, W. Va.	89,400
Dravo Contracting Co., Pittsburgh, Pa.	70,500
Green Bay Dry Dock Co., Green Bay, Wis.	69,000
John Eichleay, Jr., Co., Pittsburgh, Pa.	100,200
Riter-Conley Co., Pittsburgh, Pa.	83,610
American Bridge Co., Pittsburgh, Pa.	70,200
Midland Barge Co., Midland, Pa.	80,400

SHIPYARDS AND DRYDOCKS

Buys Shipyard, Portland, Ore.—It is reported that the plant of the Peninsula Shipbuilding Company at the foot of McKenna avenue has been purchased by G. F. Matthews, who will operate the yard for the construction of coastwise vessels.

Floating Dry Dock, Green Bay, Wis.—Plans and specifications for the construction of a floating dry dock for the Green Bay Dry Dock Company have been completed by E. J. Morrison, consulting engineer, 53 West Jackson Boulevard, Chicago, Ill. The dock will cost about $300,000.

Plant Addition, Jersey City, N. J.—Plans have been filed by the Vulcan Iron Works, Hudson street, for the construction of a one-story addition to its plant to cost $17,000. Equipment to be installed in this new building is not included in the sum above mentioned.

New Shipbuilding Firm, Quebec, Can.—A new shipbuilding company has recently been organized with a capital of $500,000. The company will establish a yard on the St. Charles River and will employ about 500 men. G. LeClarc, O. Lemay, P. Lepage, A. Milville and F. Choquette, all of Quebec, are interested.

Shipyard Sold, New Orleans, La.—It is announced that the buildings of the Foundation Company's shipyard, which were erected and equipped by the French Government in 1917 at a cost of more than $2,000,000, have been sold at auction for $35,100 to the Oliver H. Van Horn Machinery Company, of New Orleans.

New Company to Operate Yard, Boothbay, Maine.—The Reed-Cook Construction Company was recently organized and has acquired the yard of the East Coast Ship Company for operation. Irving W. Reed, of Boothbay, and Fred M. Cook, naval architect, formerly associated with the Bath Iron Works, are interested in the new company.

May Build Dry Dock, Jacksonville, Fla.—It is reported that the Merrill-Stevens Dry Dock and Repair Company contemplates the construction of a 10,000 ton dry dock, and have had plans under consideration at any time the return of prosperity to shipping lines seems permanent. With the deepening of the channel, larger ships will be coming into Jacksonville and a dock of this size will be necessary.

Shipyard Equipment Sold, Aberdeen, Wash.—The United States Shipping Board has offered for sale all equipment and supplies of the Grant Smith Porter shipyard, comprising supplies having an original value of $300,000 and plant equipment including engines, cables, motors and boiler, as well as miscelleaneous machinery, valued at $200,000. According to Mr. W. F. White, of the Tacoma office of the Shipping Board, the entire holdings will be sold piece by piece, and no sale shall be made for less than $100. Disposal of this yard will mark the closing of one of the wartime yards started by the Board in 1917.

To Build Pontoon for Dry Dock, Seattle, Wash.—It is announced by C. W. Wiley, president of the Todd Dry Docks, Inc., that work would commence at once on the fifth pontoon for the company's large floating dry dock, the construction of which is estimated to cost about $175,000. The fifth unit will also be constructed at Port Blakely as were the other four. This additional pontoon will give the dock a total length of 520 feet, thus insuring the largest ships coming to Seattle, of placement in dry dock without possibility of dangerous overhang.

Proposed Shipbuilding and Repair Plant, Jersey City, N. J.—The Weehawken Dry Dock Company, through Counselor George L. Record, has presented

plans to the city commissioners of Jersey City, N. J., for the construction of a huge shipbuilding and ship repairing plant on a site including part of Jersey City's south cove adjoining the Morris Canal and lying east of Henderson street. The plant would be built immediately provided the city grants the lease asked for, which is for twenty-five years, with an option of renewal for a similar period at the expiration of the first lease. The company proposes to pay a rental to the city of 60 percent of the rate now being paid, and to expend $300,000 for the development of the tract, dredging it, and erecting the shipyard. This project would provide employment for at least 2,000 men.

PORT IMPROVEMENTS

Dock Improvements, Sarnia, Ont.—Extensive improvements to their docks are contemplated by the Port Huron-Sarnia Ferry Company of 304 Quay Street, Port Huron, Mich. Henry M. Morran is president and general manager of the company.

Steamship Terminal Facilities, Charleston, S. C.—The Clyde Steamship Company is reported as contemplating the enlargement of their terminal facilities. Edward A. Kelly is general manager.

Piers, St. Petersburg, Fla.—The city plans to expend at least $200,000 for the restoration of the temporary pier and contemplates building a pier to cost from $500,000 to $1,000,000. Further information may be obtained by addressing the mayor.

To Rebuild Piers, Weehawken, N. J.—Plans are under way for rebuilding the Erie Railroad piers along the Hudson River which were recently destroyed by fire. The work is estimated to cost about $1,500,000. R. C. Falconer, 50 Church Street, New York, is engineer for the company.

Will Replace Dock, New Orleans, La.—The New Orleans Dock Board is completing plans for the construction of a banana loading wharf for the Cuyamel Fruit Company to replace the docks which were recently destroyed by fire. H. M. Gallagher is engineer in charge for the board.

River Terminals, Vicksburg, Miss.—The Federal Barge Line, of which J. T. Atkinson is general agent, Memphis, Tenn., has purchased a site for river terminals. The sum of $400,000 has been appropriated for this project.

Harbor Improvements, San Pedro, Cal.—A comprehensive program for harbor improvements was outlined recently at a meeting of the harbor commission with representatives of the local commercial organization.

Dredging, Lake Worth, Fla.—The Lake Worth Inlet Commissioners have let a contract to the Anderson Dredging Company for the excavation of 20,000 cubic yards of rock and dirt from the Lake Worth Inlet channel, the work to cost about $100,000.

Terminal Facilities, Corpus Christi, Tex.—The city will vote February 23, 1922, on $1,000,000 bonds for the purpose of establishing a navigation district and terminal facilities in connection with a deep water port. T. M. Lawrence is county commissioner.

Pier, Wildwood, N. J.—The Serpentine Railway Company, 2016 West Lippincott Street, Philadelphia, plans the construction of a 200 by 400-foot concrete and timber amusement pier, to cost $250,000. S. G. Matthews, 2016 Lippincott Street, Philadelphia, is engineer.

Wharves, Pensacola, Fla.—The City Commission contemplates the improvement and extension of terminal facilities, involving the expenditure of about $200,000. They propose to acquire the Palafox wharves and adjacent property.

Canal, Georgetown, S. C.—The Rivers and Harbors Committee of the Chamber of Commerce of Georgetown, S. C., W. D. Morgan, chairman, is reported as contemplating the construction of a canal between Georgetown and McClellanville, as part of the inland waterways system extending from Maine to Florida.

Dock Equipment, Tacoma, Wash.—G. W. Osgood, port engineer of the Port of Tacoma, 612 Tacoma Building, will receive bids next February for four 3-5 ton steel cranes of the loft and boom type, one 2-ton electric monorail hoist, 220 v. d. c., about 4,000 feet of monorail trackage, as well as miscellaneous conveying equipment, etc.

Dredging, Wilmington, N. C.—Major Milo P. Fox, District Engineer, has been granted an additional $50,000 allotment for dredging and other harbor improvement work in the Cape Fear River between Wilmington and the sea. The sum of $170,000 is now available for the work. Major General L. H. Beach is chief engineer.

Dock, Tarpon Springs, Fla.—The city is considering the construction of a dock to cost $30,000 for the sponge fleet.

Pier, Gulfport, Fla.—The city will rebuild a 500-foot pier with a "T" head. For further information address the mayor.

Dock and Boathouse, Osceola, Mo.—The Osage Resort Company plans a dock and boathouse on the Osage River, to cost $50,000. G. E. Linn is manager.

Flour Depot, Mobile, Ala.—The Dixie-Portland Flour Company, Memphis, Tenn., contemplates the building of a flour depot on the river front at Mobile.

Concrete Wharf, Houston, Texas.—T. Tellepsen, Prince Building, has been awarded a contract for the construction of a concrete wharf on the Houston ship channel at a price of $189,140.

Municipal Dock, Etc., Bradentown, Fla.—The city Board of Trade contemplates a bond issue and has approved plans for the construction of a municipal dock and waterfront park.

Pier Extension, Bay St. Louis, Miss.—The Hancock County Supervisors have let a contract for building a 150-foot extension to the Bay St. Louis automobile ferry pier.

Docks, Warehouses, Etc., Miami, Fla.—The city has voted $200,000 bonds for two docks, two warehouses and railroad tracks, etc., as well as 100,000 cubic yards of excavation. C. W. Murray is city engineer.

Dredging, St. Petersburg, Fla.—The city plans to dredge Bayboro Basin, involving 100,000 cubic yards of sand and rock excavation, costing $50,000. R. E. Ludwig is engineer.

GOVERNMENT WORK

Dredging, Norfolk, Va.—Specification 4553. The Bureau of Yards and Docks, Navy Department, Washington, D. C., plans dredging in Norfolk harbor.

Seawall, Puget Sound, Wash.—Specification 4562. The Bureau of Yards and Docks, Navy Department, Washington, D. C., plans the construction of a seawall.

Fire Protection System, Charleston, S. C.—Specification 4558. The Bureau of Yards and Docks, Navy Department, Washington, D. C., plans a fire protection system.

Dredging, Newport, R. I.—Specification 4552. The Bureau of Yards and Docks, Navy Department, Washington, D. C., plans dredging at Goat Island.

Piping, Charleston, S. C.—Specification 4557. The Bureau of Yards and Docks, Navy Department, Washington, D. C., plans the installation of piping for an air compressor.

Quarters, Duluth, Minn.—Specification 4549. The Bureau of Yards and Docks, Navy Department, Washington, D. C., is planning quarters at the radio station.

Distilling Plant, Key West, Fla.—Specification 4546. The Bureau of Yards and Docks, Navy Department, Washington, D. C., plans a distilling plant.

Wharf Repair, Parry Sound, Ont.—The Dominion Government, Ottawa, Canada, has awarded a contract to Weddell & Saunders, Trenton, for repairing the wharf at a price of $28,866.

Turbo Alternator, Pearl Harbor, T. H.—Specification 4548. The Bureau of Yards and Docks, Navy Department, Washington, D. C., plans to install a turbo alternator.

Dredging, San Francisco, Cal.—The United States Engineer Office has let the contract for dredging in Richmond Harbor, Cal., to the United Dredging Company of Oakland, Cal., at a price of $143,807.

Substation, Etc., Boston, Mass.—Specification 4550. The Bureau of Yards and Docks, Navy Department, Washington, D. C., plans a substation and distributing system at the naval dry dock.

Air Compressor, New York.—Specification 4555. The Bureau of Yards and Docks, Navy Department, Washington, D. C., plans to install a reciprocating air compressor.

Pier Extension, Puget Sound, Wash.—Specification 4556. The Bureau of Yards and Docks, Navy Department, Washington, D. C., plans to rebuild and extend Pier 5.

Electric System, Etc., San Diego, Cal.—Specification 4559. The Bureau of Yards and Docks, Navy Department, Washington, D. C., plans the installation of gas, water, sewer and underground electric systems, to cost about $100,000.

FOREIGN ACTIVITIES

Motorships, Middlesbrough, Eng.—Two motor cargo vessels will soon be constructed at the yard of the Furness Shipbuilding Company for the account of Furness, Withy & Company. The engines for these vessels are to be of the Tosi type, built by Richardson-Westgarth & Company. The twin screw installations in these ships will develop 2,500 brake horsepower.

Launch First Vessel, Scotstoun, Scotland.—The Blythswood Shipbuilding Company, Ltd., launched its first vessel for Chilean owners on December 15. The vessel is constructed on the Montgomerie-MacMillan system of double bottom construction.

Extensions to Harbor of India.—It is reported that proposals for harbor extensions at Bombay, Calcutta, Kurrachee and Rangoon are under consideration and will soon be taken in hand.

New Steamship Company, Kovno, Russia.—According to a report from Kovno, a new Lithuanian steamship company has been organized, supported by American capital. The company, which will trade mainly in the Baltic, is said to have a capital of $300,000 and to have purchased six steamers in England.

More Motorships, Sweden.—Another Swedish steamship company is reported to have sold four of its steamers, comprising a total of 40,000 tons deadweight, with the intention of using motor vessels in their stead. The company proposes to build sixteen more motor ships.

New Steamship Line, Oscarsham, Sweden.—A new steamship company has been formed to be known as the Rederiaktiebolaget Vallde, with a minimum share capital of 100,000 crowns and a maximum of 300,000 crowns. It is announced that the Rederiaktiebolaget Aeolus has increased its share capital to 750,000 crowns.

Wireless Station, Norway.—According to reports received by the Department of Commerce, Washington, D. C., the sum of 10,000 crowns has been voted for the establishment of a wireless station at Tramso, Northern Norway. The total cost will be 1,250,000 crowns.

New Norway Dock.—Improvements are contemplated in Northern Norway according to reports received by the Department of Commerce, Washington, D. C., the developments in Trondhjem which are already under way being the most important. The new dock for pumping pyrites into ships will cost over 2,000,000 crowns and is planned for an anticipated annual export of 120,000 tons. A new steel bridge will soon be constructed to cost about 3,000,000 crowns. Harbor work is also planned in Finmarken.

Shipbuilding, Lubeck, Germany.—The 5,400 cargo steamer Freifeld has been launched from the yard of the Schiffs & Dockbauwerft Feldner, A.G., Siems, near Lubeck, for the account of the Continentale Reederei A.G., Hamburg, to be placed in their transatlantic services. A sister ship, now under construction for the same company, will be launched in a few weeks, at which time the keel for the first of six vessels of similar tonnage will be laid for the Hamburg American Line.

North German Lloyd Activities, Germany.—It is reported that the North German Lloyd will increase its capital to 600,000,000 marks. The company now has under construction in the Schihau Yard at Danzig a 35,000-ton liner to be placed in the New York-Bremen service when completed, according to latest information. Plans for the company's rehabilitation of its position on the seas have been outlined, and according to Mr. Ehlers, an official of the line, the company now possesses the Vegesack and Bremerhaven, built last year, and both in the Brazilian service; the Westfalen, Holstein, Gotha, York and Gottingen, as well as the Hanover, repurchased from England.

Three Steamers Ordered by Japanese. — The Japanese steamship firm, Tenge & Company, of which Kaiyosha Company, 5 Canton Road, Shanghai, are agents, have placed orders with the Kiangnan and Mitsubishi Docks for the construction of three steamers. The steamers are expected to be launched in March and immediately put into service on the upper Yantze on the Ichang-Chungking run. The vessels will be of uniform size, each 205 feet long, 31 feet beam, and 17 feet deep.

Pier, Hongkong, China.—Bids are being asked for the construction of a reinforced concrete pier, 160 feet 8 inches long by 41 feet 4 inches wide, and approach at Queen's Stature Square.

STEAMSHIP INTERESTS— *(Continued)*

Danzig has been put into effect by steam ship companies at Montreal. Westbound rates from those ports were lowered $1.00 more. The International Mercantile Marine Company recently announced a reduction of 20 per cent in third class passenger rates to European ports. Most of the transatlantic steamship lines operating to continental ports will make a cut in their third class passenger rates, it is reported, the cuts amounting to from $20 to $40. The regular 10 per cent winter reduction in the first and second class passenger rates is now in effect.

BUSINESS NOTES

The firm of Rossell and Thayer has been given exclusive rights for the Philadelphia district by the McNab Company, Bridgeport, Conn., to sell their specialties, with Trenton and Wilmington as the northern and southern limits. In addition to their line of engine direction indicators, logometers and instruments of that character, and their salt detector, boiler circulator, loading draft gauge, the McNab-Vickers lubricated stern tube and the McNab-Kitsell hose couplings, they hold the United States rights for many other marine specialties. Rossell and Thayer have also been given the same territory by the Diamond Power Specialty Company, for the marine field, to sell the Diamond soot blower.

Consolidating the Small Tool and Drill Divisions, the Greenfield Tap & Die Corporation of Greenfield, Mass., has placed P. T. Irvin, formerly manager of their Drill Division, in charge of the consolidation, which will be called the Small Tool Division. Mr. Irvin has for the past three years been sales manager of the Lincoln Twist Drill Company, and prior to that was sales manager of Wells Brothers Company, of Greenfield.

The Atlas Valve Company, manufacturers of reducing valves, pump governors, and regulating devices, are now represented in the cities of Chicago and Detroit, through the offices of the Maher Engineering Company. The Detroit office is located at 744 David Whitney building and the Chicago office at 30 North Michigan Boulevard, in charge of Mr. E. E. Maher.

The Whiting Corporation, Harvey, Ill., has purchased a controlling interest in the Grindle Fuel Equipment Company, manufacturers of complete powdered coal plants for use in connection with malleable furnaces, annealing ovens, steam boilers, billet heating and various other types of furnaces. The Grindle Fuel Equipment Company has moved its offices to Harvey, and will continue its business under the same name. The Whiting Corporation will manufacture all Grindle equipment.

The firm name of Struthers & Barry has replaced the name of Struthers & Dixon, of San Francisco, due to the fact that Fred M. Barry has become a partner in the firm, replacing Captain Andrew Dixon, who retired some months ago.

David G. Reid, Inc., ship brokers, have removed their offices to 12 Broadway, New York.

The Thorndyke-Trenholme Company, a Pacific Coast shipping and chartering firm, has opened a branch office at 17 State street, New York, in charge of Emerson J. Griffith, eastern manager. The company's headquarters are in Seattle. Mr. Griffith was formerly assistant to the vice-president and general manager of the Admiral Line in Seattle.

TRADE PUBLICATIONS

Achievement in Motorships—The McIntosh and Seymour Corporation has issued a catalogue outlining the development of the present Diesel engine designs being produced in the plant at Auburn, N. Y. The American rights for this engine with certain modifications were obtained in 1913 from the Aktiebolaget Diesels Motorer of Stockholm, Sweden. The experience and facilities of this company for engine work are the result of twenty-one years service. Details of the fabricating of the engines in the shops, their installation and operation in motorships are described and illustrated, comparative diagrams and charts are also shown giving the economies possible with motor driven vessels.

Valves—Types of valves and asbestos packed cocks for every manner of marine and stationary service are illustrated and the specifications and uses outlined in a book issued by the Pratt & Cady Company, Inc., Hartford, Conn. This catalogue supersedes all previous issues and the terms, discounts, prices, guarantees and the shipment allowances mentioned are correct to date.

Normand Diesel Motors—A unique method of presenting information on Diesel motor products by a foreign firm is embodied in a catalogue which has been received from the Chantiers et Ateliers Augustin Normand, Le Havre, France, in which transparent insert pages give the English translation of the original French details of Normand Diesel engines. A history, well illustrated with views of the plant is given of the Normand Works, together with lists of ships fitted with Normand engines. The book also contains a complete treatise of the theory, design and manufacture of the various parts of the engines. Seven plates are bound in the catalogue giving plans and arrangements of engines and ships up to 7,200 tons deadweight capacity. The engines for these ships range from 500 to 1,350 horsepower, the 7,200-ton cargo ship having two of this latter power for her propelling unit.

WE GUARANTEE that of this issue 5,300 copies were printed; that of these 5,300 copies, 4,006 were mailed to regular paid subscribers, 502 were provided for counter and news company sales, 262 were mailed to advertisers, 37 were mailed to employees and correspondents and 493 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 11,050—an average of 5,525 copies a month.

MARINE ENGINEERING is a member of the Associated Business Papers, Inc. (A. B. P.), National Association of Periodical Publishers, Inc., New York Business Publishers' Association and the Audit Bureau of Circulations (A. B. C.).

Requests for change of address should reach us two weeks before the date of the issue with which it is to go into effect. It is difficult, and often impossible to supply back numbers to replace those undelivered through failure to send advance notice. In sending us change of address, please be sure to send us your old address as well as the new one.

Motorships

THIS issue is devoted largely to motorships and Diesel engines because the developments in this department of marine propulsion are particularly significant at this time. Two large motorship passenger liners have just been completed for the British-African and British-Indian trade, two large motorship cargo vessels, the *Californian* and *Missourian*, are nearing completion in America and plans for several passenger, cargo and Government vessels to be equipped with Diesel engines have been prepared.

With the purpose of giving its readers complete information on these recent developments, MARINE ENGINEERING AND SHIPPING AGE has secured and reproduced in this issue at a large expense the drawings of the *Domala*, which is the first large vessel specially designed as a motor passenger ship; the drawings of the *Californian* and *Missourian*, which are the largest cargo vessels originally designed as motorships that have been constructed in an American yard; the drawings of the *Zoppot*, the largest motorship oil tanker, the drawings of several foreign and domestic motor towboats and an article by Commander S. M. Robinson on the Diesel electric motor drive. Complete information relating to the above mentioned vessels has not, to our knowledge, been published in any other American magazine.

Does New York Really Want an American Merchant Marine?

WHILE the fact that most of the important newspapers of New York city are opposed to a subsidy in any form for our merchant marine does not necessarily mean that they are against American ships, yet the continual indulgence in destructive criticism of Governmental aid to shipping while remaining silent on the protection that is given to manufacturing and agriculture through the protective tariff and the absence of any practical constructive suggestions to take its place would indicate that the sentiment of the largest seaport in the country as far as shipping is concerned is distinctly the preservation of the "status quo."

The newspapers which are horrified at the suggested indirect tax on the American people of say 10 percent of the custom receipts, which would amount to about 30 cents per capita per annum, are not worrying at all about the loss to the country of several hundred million dollars in freight money. In fact they have suggested that the payment of this ship hire would be a possible solution of the settlement of the debts that are due us from foreign countries.

It is quite possible that the shipping nations could settle their obligations to us in a very short time were we to be foolish enough to depend on them for our ocean delivery wagons. Once assured that we are out of the shipping game, they would promptly charge us what they like and they would see to it that our goods were delivered not too soon after merchandise of a similar nature from their own country to in anywise embarrass its sale. In other words, it would become impossible to keep any trade secrets and the foreign merchants could not be blamed if they were to make use of the information gathered from their shipping organizations to anticipate our markets.

Again suppose an English ship were to be in New York harbor when it received simultaneous offers, one to take coal from Newport News to Buenos Aires at $5 a ton and another to take coal from Cardiff to the same port at $4 a ton. What would be the natural and, at the same time, patriotic thing for the owners of the ship to do? Would it not be to try and find a consignment to England, not only for the purpose of taking the coal from Cardiff but also so that more time would be available to secure a return cargo from Buenos Aires?

Then why are the newspapers of New York city against Governmental aid for our shipping on the one hand and jealous of the city's leading position as a shipping port on

the other hand? Is it because the financial interests that dominate the shipping from our leading seaport are afraid that the development of an American merchant marine would create competitors in this and other ports and they are quite satisfied to leave well enough alone, or is it because they cannot see that a tariff on wheat or a manufactured article is the same kind of protection that they are so horrified at seeing extended to shipping?

Thirty-three Knot Passenger Liners

THE proposal to complete certain of our scrapped battle cruisers for the Atlantic passenger service seems to have aroused the British interests, there having appeared in print several statements relative to the projected construction by the British with Governmental aid of a fleet of fast liners, capable of making the transatlantic run from Ambrose Lightship to Lands End in three days. Such vessels are probably practicable from an engineering standpoint. They could accommodate a large number of passengers. They would have a certain advertising value. Nevertheless to put them into service and to maintain anything like the schedule suggested would involve an enormous expenditure, even for a strong Government. The following considerations will, it is thought, lend force to this statement:

Assume a vessel of the following characteristics: Length, 1,000 feet; beam, 105 feet; draft, 38 feet; displacement, 65,000 tons; longitudinal coefficient, 0.58. At 36 knots such a ship would require about 280,000 shaft horsepower and at 33 knots (the speed suggested) about 190,000.

Assume that this ship covers a distance of about 6,300 nautical miles per round trip at a fuel consumption (while at sea only) of 1.1 pounds of oil per shaft horsepower hour. The oil fuel burned per round trip would be nearly 18,000 tons. The cost of oil in such quantities would seem almost prohibitive. It would be hardly possible to carry this amount in the ship's bunkers at one time so the vessel would have to fuel at both ends of her trip.

It is also probable that present day merchant practice with regard to the duty of marine boilers would have to be modified in the case in hand in favor of higher pressures in order to get the steaming capacity required into the ship.

Again it would probably be necessary to resort to 6 screws at a somewhat decreased efficiency compared with the 4 screw installations, with which we are familiar, in order to keep the power per shaft within reasonable limits.

The disposal of the waste gases from a boiler installation of such size is no small problem, particularly when interference with valuable passenger carrying space is considered.

The design of a hull of the size and type suggested which would have the requisite local and girder strength is a serious undertaking.

The foregoing problems, though presenting real difficulty, can doubtless be solved by the designer of today. It may be open to serious question, however, whether it is practicable to drive such a vessel with regularity under ordinary weather conditions in the North Atlantic at speeds approaching 33 knots without excessive damage to upper works and consequent undue expense and possible risk of life.

When it is considered that about 90,000 shaft horsepower for the battle cruisers and about 100,000 shaft horsepower for the vessels having the dimensions noted above would insure a service speed of 25 or 25½ knots and that such a machinery installation would simplify design and construction and greatly reduce the first cost and cost of operation, it appears that the price that would have to be paid for the high speed proposed is prohibitive. But it also shows that the conversion of the battle cruisers into passenger ships, which from an engineering standpoint can be easily accomplished, according to the views of some of our foremost naval architects, is by no means so impracticable from a business standpoint as some people would like to have us believe.

Whether or not the proposal to construct these fast liners is a result of the possibility of the conversion of our own battle cruisers into passenger ships, it shows that the British are well aware of the value of this type of vessel for both war and commercial purposes. No comparison of the naval strength of two countries that does not include the convertible merchant tonnage is correct and, if our statesmen overlook this fact, we may be sure that those of other countries will not.

Shipowners Must Do Their Part

NOW that Congress is to be asked to pass a subsidy bill, it is incumbent on the shipowners themselves to practice the strictest economy in the operation of their vessels. Great strides in this direction have been made by several concerns along the lines of reduced personnel and office expenses, lower manning scales on their ships and the reduction of crews' wages and subsistence allowances.

There remains, however, much that can be accomplished by the economical use of fuel. We assume that very careful consideration will be given to the machinery installations of prospective ships but are there not opportunities to increase the efficiency of a large number of our existing vessels?

In this connection, we note in the annual review number of the Liverpool *Journal of Commerce* that "superheaters for marine boilers are now becoming the rule rather than the exception." If English shipowners reduce their fuel bills by using superheaters and many of our shipowners do not, an opening is furnished for those who oppose subsidies to ask an embarrassing question.

In a like manner, anyone who has witnessed the amount of soot escaping from the stack when soot blowers are in operation cannot fail to be impressed with the possibilities that this equipment offers for saving fuel. There is no material that ranks higher as a non-conductor of heat than soot. Are your boilers fitted with this device?

Space does not permit a discussion of bunkering schedules, care of fires or the economical use of steam after it is generated. It is well known, however, that all these departments offer excellent opportunities to make a real saving in the cost of operating a ship. Our readers' attention is invited to an address by Mr. R. H. M. Robinson appearing on page 85 and an article by Mr. R. E. Annin published on page 83 of this issue. We shall not deserve a subsidy unless every effort is made to reduce operating costs to a minimum.

Governmental Aid

CALL it by whatever name you please, a subsidy of some form or another must be granted to American ships or our merchant marine will disappear from the seas. On this question practically all marine authorities agree, qualified, of course, by the reservation that the amount of the subsidy should not be in excess of that which is necessary to maintain in successful operation only those vessels that are of desirable design and efficiently managed.

A good and sufficient argument for the prompt passage of the Governmental aid that the President will shortly ask Congress to give our merchant marine, and which did not exist at the time the Gallinger subsidy bill was defeated by three votes in the House, is the fact that the Government will be able to save many millions of dollars by granting a subsidy that will make it possible to dispose of the Shipping Board vessels to private owners.

Not only is there no chance to interest private capital in the Government-owned vessels, 1,000 of which are now tied up, without some assurance that shipping as well as other industries will receive some form of protection, but there is also no other method by which the enormous drain on the public treasury which is caused by the care and upkeep of these tied-up vessels can be so efficiently stopped.

Having Chairman Lasker's figures, which were recently given to the Committee on Appropriations, to the effect that only one of the four millions that at present constitute the monthly loss of the Shipping Board is going for actual operations, the so-called "Watch Dogs of the Treasury" will think twice before they vote against a bill that is the only hope of getting the Government out of the shipping business.

The Next Marine Exposition

THE American Marine Association, formerly the Marine Equipment Association of America, has secured the Grand Central Palace for the next annual marine exposition, which will be held during the week of November 6. Although the first exposition was held at a time of severe business depression, it was an unqualified success, which was due in a large measure to the splendid cooperation given by the practical and technical marine associations and societies.

The Society of Naval Architects and Marine Engineers has decided to again cooperate in the coming exposition by changing the date of its annual convention from the week of November 13 to the week of November 6, thus securing the opportunity for its members to inspect the new developments in the marine field relating to their profession.

Influential members of other marine associations are known to favor holding their conventions during the week of the exposition.

The American Marine Association, in addition to sponsoring the annual marine show in New York, will function during the year as a Chamber of Commerce in the marine field, thus enlarging its scope to include any legitimate opportunity to aid in the development of an adequate American merchant marine.

The President's Shipping Plan Will Succeed

Watchdogs of the Treasury Know That the Nation Will Save Millions of Dollars by Protecting Our Merchant Marine

By "Old Scotch"

AT this writing plans for a comprehensive system of aiding the American merchant marine are rapidly taking form. Lines are already becoming drawn as to the attitude individuals, associations and the public press will take in the approaching contest before Congress. As the action of that body is largely guided by public opinion, especially on the eve of an approaching election, it is well for those of us vitally interested in the subject, and that includes everyone directly or indirectly connected with the shipping industry, to look about and see what the future portends.

Already the writer has heard quite a number of men prominent in the industry express grave apprehension of the outcome, their fears being based on the failure of past attempts and what they consider the widespread disapprobation of the public concerning the aiding of any one industry at the expense of the general Government.

Attitude of the General Public Favorable

The writer has as wide an acquaintance among people generally as the average man, and perhaps more. Thus far he is happy to state that this feeling of apprehension seems to be confined to those in the industry. It has been most pleasing to him to note the almost general approval of the scheme among the laymen with whom he has discussed the general subject. Such expressions as, "Why, of course, we must subsidize our merchant marine: we cannot expect Americans to go to sea for the same rate of wages paid to foreigners." "What is the use of temporizing with the subject: we must have a merchant marine and we are willing to pay for it," are quite frequent among people who have no direct connection with shipping whatsoever.

The writer talks merchant marine and subsidy on every occasion which presents itself, and to all classes with whom he comes in contact. Having a very good recollection of the two previous attempts to enact legislation for direct aid to our shipping, he has reached the conclusion at this stage of the present agitation that a marked change has come over the public generally in its attitude towards and its knowledge of shipping. He therefore wants to go on record in predicting that whatever relief President Harding may see fit to recommend for our shipping in the foreign trade, the measure will be enacted by Congress without any great opposition. In support of this prediction the following reasons are submitted.

Why Congress Will Aid Shipping

At the time the last subsidy measure was before Congress, it is estimated that there was not more than two hundred millions of dollars invested in ships capable of engaging in overseas trade. The people of the South and Middle West were not in the least interested in shipping, and were almost unanimously arrayed against the principle of what they

termed special privilege to any industry. English and German steamship interests, fearing the loss of trade on the ocean, waged a vicious propaganda against the proposed legislation, which was very easily swallowed by people in the Middle West, who then had not become educated to the national value of shipping and who, in common with the rest of us gullible Americans at that time, had not learned to discern foreign propaganda in our daily press, thinly guised as it was then put up to us. Our export trade in manufactured goods was very small in volume, the products of the soil and mines sent abroad then predominated to a marked degree.

Despite this comparative lack of interest and of powerful backing in any particular line, the so-called Gallinger-Frye bill passed the Senate by a very substantial majority and only failed of passage in the House of Representatives by one or two votes. A dissension among the Republican members from Illinois was really the cause of failure. Strange as it may seem some of the strongest and most intelligent backing for this bill came from the states of Ohio, Indiana and Illinois. No one of these three states could by any manner of means be accused of having direct interest in maintaining American ships in the foreign trade. The underlying motive of the supporters of this measure, who lived in these states, was vision and broad-minded statesmanship. "Uncle Joe" Cannon, still in Congress at eighty-five years of age, was one of the warmest supporters of the measure.

Let us now take stock of the changed conditions which will exert influence on the passage of the next bill.

Our Need for Ships and Shipping Universally Recognized

Basically we have changed our economic conditions so that now our manufacturing interests exceed our agricultural and mining efforts. We have not less than 15 percent of surplus products which must be sold abroad, in competition with other producers which have their own ships to deliver their goods in these competitive markets. It needs no complex argument to convince even a schoolboy that no concern can sell its goods in competition without having its own delivery system. That fact is pretty thoroughly grounded in the minds of all American citizens.

Before we entered the great war there was an insistent demand for the products of the American farms and factories throughout all Europe. We had the orders and the goods to fill them but, along in 1914 and 1915, it suddenly dawned on our exporters that we did not have the ships in which to deliver them. Germany's entire merchant marine had disappeared from the seas. England's cargo ships, as well as those of many of the neutrals, were being ruthlessly "strafed" by the relentless German U-boats. Our wharves and freight yards at the leading American seaports were rapidly congested and all of us along the seaboard became familiar with stacks of machinery and manufactured goods dumped along the railroads, sometimes three or four miles away from the wharves, because there were not sufficient ships to carry the goods to suffering Europe. The farmer and manufacturer in the interior were acutely aware of the lack of shipping facilities, when their bankers could not advance them money on undelivered goods. All of this has sunk deeply in the minds of the people, and shipping is now throughout the length and breadth of our land viewed much more intelligently than ever before.

Another factor, also a heritage of the war, must be taken into account and that is that the three million and over of the picked young men of America, the very flower of our country, have made at least two ocean voyages on their way to and from the battlefields of France. The majority of these had to travel under foreign flags, owing to an insufficient number of American ships. However, the main point to them and to the country is that they now have an intelligent idea of ships and the ocean. Every city, town and hamlet throughout the land now contains among the population at least one or more intelligent young men who can speak knowingly of the value of ships and discourse to their associates on their experiences at sea. Ships and shipping are no longer enigmas to the ranchmen of Wyoming, the cotton planter of Texas or the farmers of Kansas and Nebraska.

Shall We Scrap the Billions of Dollars We Have Invested in Ships?

Viewed from an investment standpoint how vastly different are the conditions now? Within the past five years it is conservatively estimated that not less than five billions of dollars of our national wealth has been invested from public and private funds in ships and shipbuilding facilities. They are not worth that much today and, if legislation is not enacted to make their operation profitable, this vast sum may as well be wiped off our ledgers. But "money talks" because of the thousands of men to whom capital gives employment to make it talkative, and it is not conceivable that people who are as shrewd in money matters as we are reputed to be will supinely lie down and see this tremendous amount of our savings entirely dissipated for the lack of a little intelligent legislation to rescue it from the scrap heap.

Viewed from a political standpoint, and everything we do as a nation has more or less politics in it, the outlook is very encouraging. Previous attempts at subsidy legislation were fought out along party lines, the Republicans favoring it and the Democrats opposed. Now it is entirely different, as party lines have disappeared. Some of the ablest proponents of all beneficial legislation are Democrats. The South is as deeply interested in shipping as are the East and West. The great Mississippi Valley, the very heart of the country, now realizes that we must have our own ships to market their products, as never before. President Harding, always a staunch believer in and a supporter of our merchant marine, deems the matter of such transcendent importance that he will appear personally before Congress and urge the passage of the legislation he deems necessary. He will not do this for party politics, but in the best interests of the nation.

Both Political Parties Pledged to Support the Merchant Marine

It must be remembered that the platforms of both the great political parties contain planks pledging each to the support and building up of our merchant marine. That is one subject upon which we, as a nation, have had but very few differences of opinion. The doctrine was first strongly enunciated by Thomas Jefferson and throughout our national history has been endorsed by the great men of both parties. What other one national policy could enlist the modern day support of such leaders as Wilson, McAdoo, Underwood, Harding, McKinley, Cannon and Jones?

They may differ as to the exact means of affording encouragement to our shipping but all recognize that whatever means are necessary must be employed. There now seems but little doubt that President Harding will present a plan for aid which both parties can get behind and push to success.

It must be done, and what *must* be done *will* be done.

This subject is so much the question of the hour for all persons interested in shipbuilding and shipping generally, that all other matters are secondary. We must therefore all of us devote our time and energy to its accomplishment. Never take it for granted that you are going to win, just have faith that you must win, but never relax in your efforts to assure success. Each reader can help the cause in some way. Convince your neighbors that it is the right thing to do, and write to your senators and congressmen that you expect them to vote for it.

Features of the New Shipping Bill

Sale of Government Fleet, Revolving Loan Fund, Income Tax Reductions, Marine Insurance, Immigration, Revision of Navigation Laws, Naval Reserve and Subsidy

By Winthrop L. Marvin*

WHEN President Harding and Chairman Lasker formally launch their shipping bill, they will present a measure of broader scope than has ever been attempted in this country. It will inevitably be known colloquially as the subsidy bill—even Senator Underwood's preferential duty plan of 1913 was so styled while it was under debate in Congress. But the new measure will undoubtedly contain far more than actual subsidy propositions. A long array of important forms of indirect assistance to shipbuilding and navigation has been commended to the Board, of which the first and the most indispensable of all is the sale of the Government-owned fleet "as rapidly as possible, at prices not to exceed the prevailing world market prices for similar tonnage." Already has the Shipping Board begun to function in this direction in the disposal of the *Tuckahoe* and *Absecon*—enabling American shipowners for the first time in a great many years to start with their capital cost on an equality with that of their foreign competitors.

Just how essential this even start is can readily be shown by a comparison based on previous and present figures. The *Tuckahoe* and *Absecon* were of a class once held at about $175 a ton, or a total price of about $900,000. At this staggering figure the annual charges for interest, insurance and depreciation on such steamers would have amounted to $117,000. Assuming that the price at which the ships were lately sold is in the vicinity of $35 a ton, these fixed charges, based on a total cost of $178,500, would be $23,205 a year.

Fixed Charges

The former capital cost would have made competition and success absolutely impossible. The present price makes success a probability. With equality in capital costs between American and foreign ships, all that remains to be covered is the higher wage and subsistence cost of American vessels, amounting in the case of such ships as the two under consideration to less than a thousand dollars a month, or $12,000 a year. This is a subsidy which seems easy and practicable. It is a small price for the American nation to pay for the service of an efficient unit of a great merchant marine.

Revolving Loan Fund

Another recommendation which the Administration, the Shipping Board and the leaders of Congress will consider in the making up of an adequate bill is a proposal for a revolving merchant marine loan fund of $100,000,000, to be applied especially to encourage the construction of liners and other special types of ships in which the American merchant service is today deficient. It is assumed, and it ought to be possible, when this fund is once secured, out of proceeds of the sale of Government-owned ships or if necessary by a bond issue, that the fund, properly handled at a fair rate of interest, would reproduce itself year after year so that no further additions to it would be necessary. Many nations have tried this plan of loans on sound business principles to encourage shipping. There is no reason why it should not succeed in our case as it has in others. For the construction of a new ship the Government loan would be one-third of the capital required, the two-thirds to embody the investment of private capital.

Income Tax Deductions

An entirely new feature in American maritime policy would be a deduction from net Federal income tax, payable by shippers or travelers, of a certain percentage of the freight moneys on either exports or imports and on passenger fares in American ships. This is an expedient of unexplored possibilities. It will certainly create a strong, constant preference for the American flag on the part of exporters, importers and travelers. It is a substitute for Section 34, subject to none of the objections of the other plan and not forbidden in any way by treaty stipulations. It is an indirect aid, but one likely to prove exceedingly potent—something which observers will watch with steadily increasing interest.

Our principal maritime competitors have dealt liberally with their shipping in the matter of depreciation since the great war. These nations have recognized the fact that actual depreciation has been abnormal and they have allowed their shipowners to work down their valuations to a point conformable to the depreciation that has actually occurred, thus placing their shipping on a conservative basis and relieving it of inordinate taxation. This is a problem of the Treasury Department, but it can be greatly facilitated by constructive legislation.

Marine Insurance

Powerful marine insurance facilities are an essential part of the development of an American merchant marine. The Shipping Board tonnage has been grievously discriminated against by underwriters, sometimes in this country and more insistently abroad. The temper of the Shipping Board is to meet this issue boldly so far as Government-owned tonnage is concerned. But it is important to remember in whatever is done in this direction that the Government must avoid any actual competition with established marine insurance facilities of the United States. The popular demand to take the Government out of business and keep it out is strong not only in the operation of the ships but in their insurance.

Immigration for American Ships

One-half of our immigration for American ships is an expedient which should appeal as just to the country, which realizes that the immigrant business is the most profitable of all. Particularly, at existing immigrant passenger rates, control of 50 percent of our immigration in American ships will do even more than direct subsidy to strengthen transatlantic liner services under the American flag. If our Government has a right to prescribe that immigration shall be limited annually to 3 percent of the immigrants of each race already in the United States, it has the right to insist that one-half of the immigrants admitted shall come in American vessels.

It is worth observing that Italy requires that none of her people shall leave Italian ports in any other than National steamers. Once adopted, this reservation of 50 percent of the immigrants to American liners will undeniably become the unchanging policy of our Government. It will help mightily

*Vice-president and general manager, American Steamship Owners' Association.

to create the large, fast steamers of prime value to the National naval reserve. A very important practical advantage is that opportunities for inspection and examination will be possible on these American controlled vessels before they arrive and that generally the immigration laws can be enforced in ways not possible on ships of alien nationality.

Revision of Navigation Laws

No general shipping measure would be adequate which did not involve a careful revision of the navigation laws and rules of the United States. For two years the Shipping Board has had the formal findings of an expert committee on this subject. As a part of a new shipping bill, or simultaneously with it, the La Follette seamen's law and other navigation laws in general should be amended in the light of the needs and principles of today. This need involve no antagonism to labor—for hereafter the labor on American ships is destined to be American and, therefore, not of a kind that instinctively assumes that capital is its deadly enemy

Naval Reserve

A popular feature of any shipping legislation will be the granting of substantial retainers to citizen officers and men of the naval reserve. Nothing will do more to increase the pride of calling of the personnel than a formal recognition of the National need of the officers and crews of the merchant service as especially valuable defenders of the country in a National emergency. Naval reserve ships flying a distinctive flag and officered and manned from the naval reserve enrollment will be a National recognition of the peculiar value of a trained and loyal seagoing personnel. It is true that the old "international" seamen's unions, composed chiefly of aliens, will fight this policy as they have always fought it, but it is full time that these sinister organizations were wholly and forever eliminated from the new merchant marine.

Subsidy for Overseas Shipping

Indirect aids like most or all of the foregoing can be utilized in part to cover whatever higher cost of construction there may be for the new liners and for special types of ships that may have to be added for the purpose of creating a thoroughly symmetrical fleet, in addition to the war-built cargo steamers. But these indirect aids themselves will not suffice. There is undoubted need of direct aid by subsidy also. Those who have given counsel to the Shipping Board on this point have urged that the subsidy to cargo ships and to the faster liners altogether should ultimately be limited to about $30,000,000 a year, or one-tenth of the anticipated revenue from customs. It is an expert estimate that such a subsidy expenditure would cover a very large complete fleet of overseas shipping of about 7,500,000 tons gross register, capable of carrying between 50 and 60 percent of the whole seaborne commerce of America. This subsidy would be paid to privately-owned ships and to Government-owned ships as fast as they are transferred to private capital and enterprise. This would produce a powerful incentive for the purchase of the Government-owned tonnage by equalizing competition with foreign ships and making it possible to operate tonnage under the American flag in world commerce.

An expenditure of $30,000,000 a year is greater than was contemplated in the Frye-Hanna bill of 1901 or the Gallinger bill of 1905, but it must be remembered that it is applicable to a far greater merchant marine, most of which is already in existence.

An Administration Measure

These are all well-considered recommendations. The shipping bill itself will be framed jointly by the Shipping Board and by the leaders of the Senate Committee on Commerce and the House Committee on Merchant Marine and Fisheries. It will not be a mere Shipping Board bill, but a distinctive Administration measure. Unlike any previous efforts this new bill is justifiable on the strong ground that it involves a reduction and not an increase of expenditures. Continued maintenance of the great organization of the Shipping Board and of the Emergency Fleet Corporation, and assumption by the Government of the losses of the operating lines and of the tremendous cost of depreciation of a thousand ships laid up, are heavier drafts upon the National treasury by several times than the entire cost of subsidy disbursements. As Chairman Lasker has again and again declared, Government operation of shipping, even by experienced and able men, is inevitably costlier than private operation, where operators have the incentive of gain and must earn a profit to secure a livelihood.

Proposed Legislation Will Save Millions

It will be demonstrated again and again to Congress in the course of the debate upon the proposed legislation that the Government will save millions of dollars a year for many years by turning the workable Government fleet over to private hands and protecting private owners and operators sufficiently to meet the competition of the lower wages and subsistence, and, in addition, of the State aid of Europe and Japan. There can, therefore, be no pretense on the part of self-appointed watch dogs of the treasury that the interests of economy demand the neglect and destruction of the new merchant marine.

The whole country is weary of Government experimentation in the shipping business. Liquidation of all the vast war-time accumulation of supplies and materials is rapidly going on and will soon be ended. Only the ships remain, and their sale also is imperatively demanded by popular opinion. The issue cannot be dodged; it cannot be ignored. The fact that the Government-built fleet is still on Government hands will keep the question of National policy for the merchant marine constantly before Congress and the country. In the recommendations presented, the President and the Shipping Board have the material for the strongest shipping bill ever written by any men in any nation and they have the spur of economy and retrenchment driving it on.

Urgent Reasons for Subsidy

If the Government is ever going to realize any fraction of the three and one-half billion dollars which the great war forced it to devote to the building of a merchant marine it must be by the sale of the better portion of the war-built fleet to men who best know how to operate these ships under conditions that will afford a living profit. No subsidy proposal has ever come before Congress with any such chance and any such urgency as this. And it is to be remembered that previous shipping bills were beaten only by desperate hyphenate opposition through a nation-wide Teuton propaganda. Moreover, friends of the American ships were then defeated only by a scant majority of from two to eight or ten in the House of Representatives.

Most encouraging is the active, organized movement of American men of business in the Middle West to impress the need of a vigorous American merchant marine upon their public men in Washington. There ought to be a similar movement among the American farmers of the Middle West, who were the heaviest sufferers when in 1914-1915, because of a lack of American shipping, the cost of transporting a bushel of wheat across the Atlantic actually amounted to a greater sum than the farmers themselves received for all the labor and expense of producing that bushel of wheat!

French Tank Steamers.—France has in service an oil carrying fleet of 41,000 tons carrying capacity. Seventeen tankers, aggregating 159,000 tons, are now under construction in France, most of which will be completed by January, 1923.

Shipping Affairs Progressing Rapidly at Capital

Committee Recommends Appropriation for Shipping Board—Chairman Lasker Prophesies This to Be Last Request to Congress

By Harold F. Lane

THE House Committee on Appropriations on January 18 favorably reported the bill providing for the appropriations asked by the Shipping Board and the Emergency Fleet Corporation for the fiscal year 1922-1923. The appropriations requested are $50,000,000 for fleet operations and $50,000,000 for the settlement of claims, of which $30,000,000 is to be immediately available. The bill also provides for continuing the appropriation of March 4, 1921, of $55,000,000 which is to be made available to the Board from the proceeds of the sale of its assets, so that the balance of that amount may be used in its operations during the coming year. For the Shipping Board itself $459,000 was recommended.

In this connection Chairman Lasker of the Shipping Board made a statement, saying that he viewed the action of the committee as a vote of confidence in the Shipping Board. He predicted that if world shipping conditions improve and Congress provides for a ship subsidy which will make it possible to sell the ships now owned this will be the last appropriation of any extent it will be necessary for the Board to ask. He said that he had not wished to make any formal statement of what had been accomplished by the new Shipping Board until it had first formally submitted all the facts to Congress. This opportunity was presented in the hearings before a subcommittee of the appropriations committee just concluded.

Indicates Reestablished Confidence

"When the present board took office," Mr. Lasker said, "the temper of Congress as evidenced in the discussions of the deficiency bill for the Shipping Board was one of lack of confidence in the enterprise and a virtual verdict that the administration of its affairs under me was on trial. In effect Congress said it wanted to be shown. After taking evidence during the past two weeks—over 400 printed pages—in what the subcommittee of the House Committee on Appropriations termed one of the most illuminating and complete hearings ever held before it as to any governmental department, and after investigating in the minutest detail every item of operation, organization and finance, the subcommittee reported favorably to the full committee, and the full committee reported favorably to the House on every request that the Shipping Board made for appropriations for the coming year. This to our mind constitutes more than a mere vote of appropriation. The subcommittee, with a thoroughness that could not be exceeded, explored every bit of work and every important transaction in which the Shipping Board is engaged and its vote to grant the appropriation to our minds constitutes a vote of confidence that inspires us to carry on the important work in which we are engaged.

"We come before Congress showing the Emergency Fleet Corporation for the first time organized as a private corporation, managed by technical men, positioned to compete with private enterprises of a similar nature in so far as that is possible under the handicap of Government ownership. We have erected in the Fleet Corporation an organization that is daily cutting out waste and chicane, and bringing into being orderly processes and improved service that should win back the confidence of the shippers. In this time of depressed world carrying trade practically all steamship companies except those exclusively in the North Atlantic passenger service are losing large sums of money. In proportion to its operations the Fleet Corporation loss is down to a minimum.

Voyage Operating Loss Less Than Million a Month

"With almost 400 ships on the seas the monthly voyage operating loss is less than a million dollars. The balance of the $4,000,000 a month which the Fleet Corporation is requiring at the present time is devoted to repairs and betterments, insurance, cost of lay-ups and administration expense. The slightest upturn in world shipping will immediately result in the voyage operations showing a profit and with an appropriation for the settlement of claims, then, when these are disposed of, a large share of the administrative expense can be done away with. The 400 ships now operating cover practically every port in the world, insuring to the American shipper delivery under the American flag wherever he wills. By proper management in Washington we have improved the service of our operators. We have reduced our payroll from practically $16,000,000 to less than $11,000,000 and at the same time immeasurably improved the character of our executive personnel. We have for the first time in the history of the Board an inventory of its assets and a statement of its assets and liabilities.

Probably Last Request

"With the appropriation asked, by the end of this calendar year the Shipping Board should be free of all debts current and claims and have only outstanding such judgments as may accrue from cases in court. With any upturn in world business the loss should cease, so it is fair to prognosticate that this, the first annual appropriation asked by the present Shipping Board will very likely be the last. If world conditions do not improve and if there is no Government aid to American shipping a slight appropriation may be needed for the maintenance of trade routes in the fiscal years 1923 and 1924 but, by and large, I feel I can verily announce to the country that the end is here of appropriations for the country's great ship enterprise.

"The record made has shown that the Shipping Board has taken the mysteries out of the history of the Shipping Board and in it its readers can find, revealed in every detail, the history of the board from its inception to the present time. We feel pardonable pride in congratulating the country and ourselves that in seven months we can say that, by and large, this is the last loss to any extent, save in the settlement of lawsuits, that the Shipping Board will be to the country. It feels good to make this announcement of an enterprise that has taken $3,300,000,000 of the country's money and to be able to say that after this no more will be needed.

"After the President makes his suggestions to Congress and if Congress should grant Government aid to private shipping we feel that we can liquidate the immense tonnage owned by the Board and that liquidation will bring back to the Treasury much more than the cost of a subsidy. If this happens, within two years I hope and believe that we will be out of Government operation and that the Shipping Board in the liquidation of its assets can be a source of income and not an expense."

Ship Subsidy Plan Soon to Be Announced

The Shipping Board's report containing recommendations on plans for a ship subsidy, the result of its study of various

reports submitted to it by a committee of experts and by the various interests concerned, is about ready to be submitted to the President, who will shortly thereafter go before Congress to urge the enactment of the legislation to carry out the plan finally decided upon. Various predictions are made as to the prospects of getting a bill through Congress and it is certain that a lively fight will ensue before the question is settled. Chairman Lasker of the Shipping Board has been making a number of speeches in various parts of the country in an effort to win public support for the subsidy idea, saying he sees no hope for the future of the American merchant marine unless a subsidy in some form is provided to aid it and that whatever it costs will be more than repaid by making it possible for the board to sell the Government-owned ships to private operators and for the Government to get out of the business of ship operation.

Flexibility Desired

Whatever plan is decided upon, the Shipping Board is anxious to have enough flexibility to the subsidy plan so that it may not be at once made ineffective by the action of some other country in increasing its subsidy to its own ships. For the same reason it is desired that Section 34 of the Jones law be retained upon the statute books where it could be used if necessary.

A draft of a preliminary report of an advisory committee of experts making recommendations to the Board was published in a number of newspapers shortly before the end of the year as representing the administration plan, but Mr. Lasker issued a statement pointing out that this was but one of several reports to be made and that the Board certainly would not approve some of the recommendations there made. The details of the Shipping Bill that the President will ask Congress to enact are outlined as nearly as can be estimated at this time on page 79 of this issue.

Proposed Form of Direct Aid

With regard to the forms of direct aid—a differential payment to American ships based on their higher wage and subsistence cost, and postal subvention to regular services—the funds to be raised by the reserving of one-tenth of the customs receipts and of the increased tonnage taxes—the American Merchant Marine Joint Committee heartily approves the recommendations that have been made to the Board. Of the three proposed plans for granting the differential payment it recommended that "whatever legislation is passed through Congress should be based on the principle of the Gallinger plan of so much per gross ton per year—the faster passenger ships to be encouraged by means of the postal subvention."

The American Merchant Marine Joint Committee believes that the legislation recommended should set forth the general principles upon which the subsidy should be granted as outlined above and that the Shipping Board should be given authority to carry out the details in accordance with those general principles.

In addition to the foregoing it was urged and recommended "that the United States Shipping Board devise some plan of equitable adjustment of the prices for the American shipowners who have purchased vessels from the United States Shipping Board and paid for same either in full or in part."

Concerning Section 34

Homer Ferguson, president of the Council of American Shipbuilders, also submitted a report on the attitude of the council toward maritime legislation, in which the council asserts its continued attachment to the legislation contained in the merchant marine act of 1920. The report said the council is opposed to the repeal of Section 28, Section 34, or of any other section of the merchant marine act which has not hitherto been put into effective operation, on the ground that "the fact that reasons of state may have hitherto prevented the enforcement of these sections, and that such reasons still exist, is no just ground for the repeal of either. They should remain upon the statute books to be instantly available when the state reasons of today give place to the state reasons of tomorrow. It may transpire that other proposed measures in aid of the merchant marine will fail of enactment, or if enacted, may prove ineffective, and if effective, may be of short life. In either of these events the existing sections would prove invaluable."

The report continued in part: "The council believes that the declaration of the merchant marine act, that the purpose of its enactment was to secure to American vessels the carriage of the greater portion of our own commerce, expressed an aspiration so just as to disarm criticism. It believes that the first step towards the accomplishment of this result is to economically exclude from our trade with all nations all ships except our own and those of the other party to the trade. Commerce between nations includes carriage. Nations stranger to the commerce should not be permitted to intrude their ships therein.

"The merchant marine act is a Congressional recognition that the American ship can not take or maintain its place upon the sea, except by effective discriminations in its favor.

Agreement on Form of Subvention Sought

"If reasons exist which at present prevent the discrimination from taking the form of preferential duties, then the less preferable form of discrimination, namely subsidy, must be enacted in the meantime unless Congress is prepared to sacrifice the substance to the form.

"This council does not favor subsidy as an alternative policy to that of the merchant marine act, or as in anywise a substitute therefor, but as a measure of relief until events permit discriminations better suited to the genius of the American people.

"This council recognizes that hitherto measures beneficial to the merchant marine have for many years been defeated by dividing the friends of the merchant marine into hostile camps, each so opposed to the relief proposed by the other, that a cause dear to both has been lost. Those who have favored subsidy have opposed discriminating duties and those who have favored discriminating duties have opposed subsidy, with the natural consequence. Repetition of such a conflict may be expected to produce a repetition of result.

"This council believes that any subsidy measure passed at this time should (a) either avoid appropriation, or if this is necessary, promise continuance; (b) it should be confined to present American vessels of approved class, or to vessels hereafter American built; (c) it should not be of a character to encourage bad ships to remain in the trade; (d) it should provide that vessels hereafter sold by the Shipping Board should carry subsidy or not, as might be provided in the sale.

"In the event that foreign objections are not controlling, it would be desirable that the measure should devote a certain fund to the subsidy, which would not require continual reference in the appropriation bill, thus eliminating the measure from the arena of politics."

Pacific Coast Pool Proposed.—President Harding and the Shipping Board have given their approval of a plan proposed by Pacific Coast interests to form a large company to buy Government vessels in operation from Pacific coast ports, the stock to be distributed as widely as possible among the people of the Pacific coast states. Plans for the creation of a $30,000,000 shipping company on the Pacific Coast will be discussed in Washington early this month, when Chairman Lasker of the Shipping Board will call a conference of the Western interests to consider means of promoting the pool.

Economical Steamship Operation and Management

Bunkers Provide Field Where Most Telling Economies Can Be Practiced—Choice of Ship and Fuel Very Important

By Robert E. Annin

ONE of the most obvious and exacting requirements of successful management is the noting and interpretation of current events and symptoms in all fields, both in relation to present action and to the formulation of the broader and more stable policies which must be framed to meet the probable needs and eventualities of the future. As the present situation clarifies with the passage of time, the market itself is seen to be running very true to form. On the one hand there is an occasional steadying of rates, with slight advance for some trades, which is the natural and predicted result of the voluntary reduction of active tonnage. On the other, it is notable that such demand as exists is almost entirely confined to nearby tonnage, which indicates, on the part of shippers, doubt as to the permanence of the present freight level. This illustrates the continuing threat of the idle tonnage and augurs ill for any immediate relief to owners so far as an increase in gross revenue is concerned.

From the broader point of view, the advance in sterling exchange is an encouraging indication so far as it goes, both as a hopeful sign in the broader fields of commerce and as an element reducing the disadvantage to American owners which was so notable when sterling was at or near bottom.

Normal Trade Awaits European Stabilization

But no real return to normal may be expected in international trade until Europe's industries have gone much further toward revival; until national budgets have been so arranged that taxation will cover expenditure; until the nations realize that the greatest asset of any commercial people is the buying and selling power of its neighbors and customers. The general failure to recognize this last truth is one of the least hopeful signs of the moment. One observer has compared the recent relapse into policies of trade control and trade barriers on the Continent as surpassing any similar situation since the mercantilism of the seventeenth and eighteenth centuries. He adds (referring especially to the new-born nations of Central Europe):

"Each of these states has been trying to render itself economically self-sufficient, through trade embargoes, restrictions and tariffs; each has, however, merely succeeded in rendering itself economically impotent."

Considering the intimate economic relations of European industries and commerce, this is not very optimistic on the general situation. This is (in essence) confirmed by nearly all qualified observers who have had both the opportunity to judge and the training which should entitle their judgment to consideration. As to our own merchant marine, recent utterances seem to indicate that systematic Government aid, such as is generally considered essential, may be on the way. In the meantime, however, owners and operators must do the best they can under the conditions as they exist. Hence the conclusion is reinforced that the only logical course to be pursued for the moment is the rigid practice of all the time-honored economies and a diligent search for new methods of reducing operating costs.

Economies Accomplished

If trade gets no worse, it is probable that the reduction of active tonnage has reached its limit. Economy in subsistence has nearly reached the same point, failing further general decline in food prices, etc. Some operators claim to have reduced this item to 50 cents per diem per capita, as against $1.25 a year ago, and about 35 cents minimum in 1913. Evidently there is not a great deal of room for further saving in this direction.

Further and progressive reductions in the pay roll aboardship are natural developments of the situation and merely confirm the expectations of the trade since the last cut was established and accepted. The Shipping Board is contemplating and private owners have established a further step in this direction—said to reach from 15 to 30 percent—and the end is not yet. No spirit of prophecy was needed to predict that this must come. The mathematics of the situation have made this reduction imperative, failing a radical improvement in business which there was no reason to anticipate last August, and of which there is no real indication now. In truth, this reduction does little than to give official sanction to a pay scale which (in the lower ratings) has been in effect for some time. This is true, at least of many private operators. Sailors, like other people, have lately been wisely applying to their own plight the time-honored proverb concerning the relative value of half a loaf and no bread.

The reduction of construction, scrapping of uncompetitive tonnage and influence of ordinary sea mortality are sure forces working toward a healthier situation in the trade itself but they are slow. The same may be said of international trade, which is, probably (below the surface) tending toward better things. Meantime present conditions must be faced at once by those who purpose to stick in the business.

All this merely clinches the conviction that plans for the future cannot safely be based on any expectation of rates higher than those at present ruling, relatively to operating costs. This can only mean that fresh economies and improved methods must be diligently thought out and put in operation. For the closest figuring in office salaries, sea payroll, subsistence and stores will take but a small bite out of the deficits which now confront the shipowner.

Importance of Efficient Personnel

The broad field in which there is yet much room for saving—direct and indirect—(a saving not easily expressed in figures, but always decisive in the year's balance sheet) is the progressive improvement in personnel, elimination of useless positions and a constant search for men who can fill the necessary jobs ashore and afloat in the most thorough and efficient manner.

This is the essence of time-honored preachments, extending from King Solomon to Elbert Hubbard, and yet it needs to be preached every day. At no time has it been more necessary than in the last seven years. As to the ship and wharf it has been more apparent and flagrant but in many offices, notably those of the newer companies, it has been not less obvious, and in the long run more expensive than inefficiency on the beach, or afloat. Longshoremen and sailors were demoralized by easy money and a surplus of jobs. But clerks, managers, operators and brokers were in many instances "put off their game" equally by the seductive influence of large pay, big profits and enormous commissions. In truth, it is a fair assumption that of the recent past troubles (as related to ship management) at least one-half were due to ignorance, carelessness, slackness and atrocious bad judgment at the shore end. The navigating end was at least protected to some extent by legal requirements as to licensed

officers but in the office manned by greenhorns (or worse) the owner's property was wholly unprotected.

The relaxing effect of the abnormal conditions and the reflex influence of irresponsible competition no doubt affected the whole trade more or less. But by far the greater part of this disturbing factor was due to the new and inexperienced element injected into the trade by the war. The name of the firms of this class was legion; their influence was widespread and most unfortunate; especially accentuating the difficulties of managing or retaining competent help. Being easy marks for the wicked, they were responsible for a very considerable proportion of the extortion and swindling which were so scandalous during and after the war; also for added inflation in every item of cost.

Attention was called in the last article to the remarkable balance sheet of a Scotch company, as showing what might be done in keeping down gross or relative expense by an efficient office force. Such results are only possible with an able and experienced personnel, working at high pressure under proper supervision.

Normal Standards Disregarded

The normal standards in this respect were nowhere maintained during the "boom" freights. Where loss of time was so expensive, it would have been the height of extravagance to sacrifice speed for the sake of economies which (relatively at least) were of minor importance. This, as a moral influence, has not yet been eliminated, although the improvement is already most marked. But in the two years succeeding the armistice it was notable everywhere. Among green operators, laxity, carelessness and even public disregard of the simplest commercial proprieties reached limits which may fairly be described as ludicrous.

The writer vividly recalls happening into one quite pretentious shipping office in mid-afternoon of a business day and finding the president, chartering manager and junior clerk shooting craps in the private office. Yet the concern was handling a very considerable business, because they had in some way secured considerable tonnage for charter and tonnage of *any* kind being then far short of an insistent demand, shippers or charterers were taking anything regardless of the source through which it was offered, and almost regardless of anything except the supreme necessity for room. Probably the crap-shooting president was being paid $20,000 per year and the total office expense was undoubtedly above $50,000.

This is an extreme case; but it illustrates an influence which was much in evidence up to the time when the freight market collapsed. Strong traces of this influence may still be noted in some quarters.

Such matters are elementary. The principles involved became axiomatic to real operators long ago, through the costly teachings of experience. During the period of depression which extended from 1901 to 1910, great progress was made along the line of scientific economy. Except for the demoralization of war markets (foreign, domestic and international), the whole trade would now be much further advanced in this respect. But as conditions now are, and owing to the continuing commercial and moral results of the big war, the shipping world has still some distance to go before it can even regain the average efficiency of 1913. War influences were demoralizing everywhere in the shipping world, but their effect was greatly more injurious here, owing to a greater expansion of activities, based on a relatively smaller nucleus of sound operating firms. The position reached in 1913, therefore, is not good enough today. Owners and operators of American tonnage must now face handicaps which did not then exist.

Foreign Exchange Not Main Cause of Depression

Reverting to the depreciation of foreign exchange, this continues a notable disadvantage to every nation, which, now, like ourselves, pays its obligations in gold or its equivalent. This, of course, includes and affects all costs down to the smallest detail.

It is very commonly stated that the depreciation of foreign exchanges is a main cause in the depression of international trade, on which ocean transportation is so completely dependent. Such statements obviously involve a confusion of cause and effect. The low foreign exchanges are symptomic —not causative. International trade is wholly out of balance owing to conditions only too obvious. Let production and consumption, export and import, resume the normal relations on which the commerce of the last 75 years has been based and the international exchange rates would again become normal. But were it today possible to re-establish by edict the pre-war rates of exchange, the normal commercial relations between nations could not thereby be restored. Disease cannot be eradicated by mere palliatives. So long as the rates of exchange continue to be so distorted, they will, to some extent, react against the interests of American tonnage in varying degrees and (so far as this influence is concerned) in direct proportion to the degree of depreciation. As matters now stand with our maritime competitors, Japanese exchange is nearest to our own and therefore least troublesome to us. Sterling, perhaps next, and German, of course, the most menacing of all.

Selection of the Ship

Assuming the most efficient and economical management as to wages, subsistence, office expense and personnel, the average operator today can at best only reduce operating losses. It is necessary to go further in the line of larger economies and the most important item of operating cost—bunkers—will provide now, and in the future, the field where the most telling economies are bound to be practiced. Leaving out the question of improvements still in the experimental, or semi-experimental, stage, it goes without saying that the first step in this direction lies in the selection of the ship. The next is of course in the choice of fuel—the kind and quality, and the bunkering schedule, which latter may vary according to prices, quality and facilities of ports at either end of the voyage.

A recent writer on this subject asserts that 40 percent of the incompetence of which we hear so much has lain in the choice of ships unsuitable for the completed service; and another 40 percent in the mismanagement of fuel. These are perhaps excessive estimates. No one will be disposed to deny, however, that the suitability of the ship to the intended service is a question with which experience alone is competent to deal, and then only when acting under able technical advice. Allowing for all the confusion and disturbance of trade, it is generally recognized that this matter has been handled, both officially and privately, with an amazing disregard of this main consideration. Sometimes it has been merely misjudgment, sometimes crass ignorance, but sometimes it has seemed to result from nothing less than criminal indifference. In many cases the financial results of such policy—or lack of policy—have been nothing less than appalling.

As to Bunkers

The rise of oil as a power producer has been sensational but, in view of the apparent limits of ultimate supply and the certain increase in demand, it is not clear that oil fuel will show a permanent advantage over coal, so far as steamships are concerned. That will depend on many factors but chiefly upon the price of oil as compared with coal and upon the added gross revenue to be gained by the use of oil.

Ton for ton, oil is of course more expensive. Its advantage lies in its greater heat producing value per ton (a given service therefore requiring a less quantity of fuel) and in the revenue to be gained from the cargo capacity released, by the use of the less bulky and weighty fuel.

Experience shows that the thermal value of good oil is about 50 percent greater than that of good coal, i. e., two tons of oil will produce about as much effective heat as three tons of coal. The waste of lift capacity in using coal is therefore 50 percent more than in the case of oil and such waste will of course appear in reduction of gross revenue paid by cargo.

When war freights were in vogue the results of this difference were amazing. At the peak of the market, and long afterwards, an "alternative burner" could not have afforded to burn coal had it been *free*. The loss in revenue on the sacrificed room would have far exceeded the total cost of fuel oil. Moreover, bunkers being unobtainable in Europe, all transatlantic steamers from this side had to bunker for the round trip, and the normal advantage of oil was thus doubled.

Therefore the advantage of oil for steam making varies with two main factors, which are the relative costs of oil and coal per ton and the level of freights.* Briefly, if oil costs, per ton, twice as much as coal, and the quantity required for a given service be one-third less (or as two to three), the relative first cost will be as twenty to fifteen in favor of coal, or a saving of 25 percent. From this, however, must be deducted the less costly bunkering and stoking of the oil, leaving a margin of first cost in favor of coal. Whenever this margin is wiped out by the increase in gross revenue, made possible by the use of oil, the latter fuel will be cheaper.

The Bunkering Schedule

But when cargo is scarce, and the ship must sail partly empty, there will be no gain in revenue and oil will therefore be less economical. The net result must also be influenced by the level of rates and length of voyage, among other conditions.

*Editor's Note: In the passenger trade, oil fuel has such an advantage in the speed and cost of bunkering, together with the extra space made available for passenger accommodations that the relative cost of coal and oil will probably not be a deciding factor for some years. For example, the *Olympic* is able to make one extra round trip per year since she was converted from a coal to an oil burner. The oil is pumped into her tanks in eight hours as compared with three or four days and over three hundred men for coaling.

With the wide difference in oil prices, here and abroad, the recovery by the English of their bunkering trade and questions as to the relative economy of different qualities to be decided (a most important point in both classes of fuel), it is apparent that there is here a large field for experience, but no place at all for novices. The planning of the long voyage bunkering schedule of the future is likely to be a work of art, requiring a high quality of technique. Certainly the subject is worth all the attention it is likely to receive. Wages and subsistence are constantly discussed and made much of, yet they amount on the average to not over 16⅔ percent of total operating expense. Fuel, on the other hand, may reach 40 percent or more on the ordinary freight carrier. Here is a field in which experience and training are imperatively required.

All these general and specific factors clearly mark the one great economy, without which all attempts at satisfactory results will be futile—a working force constantly increasing in training and efficiency, whose members fit their jobs and whose jobs fit them; extending from high executives to the junior positions; but of course being most essential in the upper grades.

The old established companies, both here and abroad, learned this long ago; and one of their many advantages over comparatively new comers lies in the quality of their selected personnel and in the fact that the best available talent naturally drifts to them. Given this instrument, the specific problems are shorn of half their terrors. Here is where most of the newer companies have been, and still continue, weak.

The greatest operating extravagance is to employ men who are too small for their jobs, because they come cheap. One piece of ignorance, or bad judgment, or bad management is apt to make any difference in salary look negligible.

There is no such major economy as a well selected and cooperating office force, and toward this end every well managed company is straining day by day. This result can only be achieved by a system of consistent and continuous selection, pursued from month to month and from year to year.

Steamship Operation and Its Problems

R. H. M. Robinson, President, American Ship and Commerce Corporation, Addresses the American Society of Civil Engineers

"A DISTINCTIVE characteristic of the shipping industry is the great mobility of its productive factors," declared Mr. R. H. M. Robinson, president of the American Ship and Commerce Corporation and acting president of the United American Lines at the annual meeting of the American Society of Civil Engineers. He referred to ships as productive factors because the services emanating from them are the merchandise of the shipowners.

In calling attention to the 60,000,000 gross tons of shipping in existence today, Mr. Robinson pointed out that "directly or indirectly, actually or potentially, every ton of this 60,000,000 is a competitor of every other ton. A ship built for the New York-South America service does not directly compete with ships operating in the North Atlantic, but it may force another ship out of the South American service and into the North Atlantic. For this reason it is wrong to say that foreign tonnage does not affect conditions in the United States intercoastal trade, for a ship built in Japan for transpacific service may conceivably force an American ship from the transpacific into the intercoastal trade."

Although Mr. Robinson called attention to the limitation of the possible competition of standardized ships with vessels specially constructed to fit the requirements of particular trade routes he claimed that the excess tonnage in the world today was a significant problem to every shipowner. "It means intense competition, scrambling for cargoes, rate cutting and unprofitable business unless the situation is adjusted, either by reduction of tonnage or increase of trade. There has been wide discussion of the advisability of an international agreement for the scrapping of the present surplus of tonnage and the limitation of future building. Most shipowners, however, are holding on as long as they can in the hope that the adjustment will come through an increase of trade rather than a scrapping of tonnage.

Advantage of Long Experience

"It is certainly not out of order to consider where American shipping stands with respect to this general situation and the long competitive struggle which is ahead of us. We suffer handicaps of a very serious nature. Our ships cost more to build, our marine wages are higher and our experience in the business is much more limited than is the case with our principal competitors. I do not intend to go fully into this subject, but there are several points in con-

nection with the last mentioned handicap—our more limited experience—which I should like to discuss briefly.

"Long experience in a business means, among other things, the establishment of helpful connections and the creation of a certain good will in the markets served. In these traffic arrangements the newer American shipping companies lacked sadly during their efforts to get going just after the Armistice. Gradually they are establishing these connections at home and abroad. Too much emphasis cannot be laid on the value of good agents abroad. It is a phase of the problem which is often underestimated. Our ships need good cargoes homeward as well as outward, if they are to yield profits to their owners.

"Long experience also has its benefits in the matter of operating efficiency. Efficiency and economy are problems in every industry and nowhere more than in shipping. It must be evident that in a business which involves such great distances as is the case with a transoceanic shipping company, and in which unexpected conditions are always arising, inefficiency and waste are likely to play a prominent part. While making no claims to exceptional talent in the eradication of these evils, my study of the problem has brought to my attention certain possibilities which may be worth mentioning.

Waste

"Waste may occur with respect to materials and with respect to services. Dealing first with materials, we may look at the question of fuel, which constitutes a very large item in the operating cost of a steamer. It is perfectly patent that a boiler may be fed to a certain point with maximum results and that fuel used beyond that point is sheer waste. Generally, engine room crews are alive to this fact, but very often they carelessly or willfully disregard it.

"Not infrequently we find that ships are driven at an uneconomical speed, thus uselessly increasing the fuel consumption. It is a great temptation to a captain to push his ship to her speed limit in order to make port some hours, or a day, earlier. It takes the closest kind of checking and control by headquarters to eliminate this form of waste; that is to say, to determine what is the economical speed of a given vessel for a given trade under given conditions, and to enforce the proper observance of that speed.

Subsistence

"As regards food, it is recognized that men must be well fed on shipboard, but the wastage that is sometimes encountered is prodigious. Certain of our ships, which have always been run on what was considered an economical basis, are now costing us no more per man per day than they were before the war, although prices are now about 50 percent higher. We have arrived at these results by giving the ships' steward a maximum figure to which to work, and discharging him if he goes above that figure without reasonable excuse. There have been relatively few discharges on this account. The men, however, are entirely satisfied with their food.

"Just as a steward may waste food, so a deck or engine crew may waste paint, lubricants and other supplies. It is a little more difficult to check up on this sort of inefficiency but there is no excuse for allowing it to run wild.

Care of Machinery

"A very common form of waste is that of letting machinery run down for want of proper attention from day to day, so that in the course of time it breaks down entirely and requires extensive overhauling and perhaps replacement of parts.

"It is wasting services to carry a crew larger than is actually required. When business was good we thought we had our crews figured down to the practicable limit, but the pressure of hard times has brought about further reductions, which on some of our cargo vessels have amounted to as many as six, seven and eight men. This has been done, moreover, without handicapping or endangering the ship.

"Services are being wasted when the crew is allowed shore leave to the extent of necessitating that shore labor be brought aboard to do the crew's work. I may say that the American law requiring the payment of half the wages due, on demand of the seamen in port, induces the men to spend more time on shore than is good for themselves or the ship, and not infrequently leads to their being left behind, or to deliberate desertions.

Port Delays

"The most extravagant form of waste is wasting the services of the ship. Several idle days at port, during which time the vessel is earning nothing and is running up expenses at almost the same rate as if at sea, may easily destroy an otherwise fair margin of profit. Every hour counts when it comes to despatching a ship and it takes the concentrated, and one might almost say consecrated, efforts of the operating department, crew, stevedores and all others concerned, to eliminate losses from this cause.

"Recently our operating department worked out a scheme for consolidating at one port fuel delays which formerly had occurred at two ports. We have not figured out exactly what the saving of this arrangement will amount to in the course of the year but it will doubtless run into many thousands of dollars.

"It is self-evident that the elimination of waste in the operation of ships requires a high degree of co-operation as between management and men, and there are many schemes for encouraging this. There is the idea of creating a competitive spirit among the men by comparing the records of different voyages and of the various ships of a fleet. There is the idea of a bonus granted to officers and crew when a ship makes a particularly satisfactory voyage. Sick benefits and superannuation funds also work in this direction. In a large fleet the promotion plan may be effectively used; that is to say, efficiency among the men may be encouraged by holding out to them the possibility of getting higher ratings with the company as a reward for faithful service."

Free Ports and Free Zones

A RECOMMENDATION that there be established in the United States free zones or free ports similar to those with which Europe is familiar was made recently by a committee of the Foreign Commerce Department of the Chamber of Commerce of the United States.

Attention is called by the Chamber's Committee to six arguments in favor of free zones, as follows:

1. Free zones will direct increased transshipment trade to American ports.
2. Free zones will provide facilities for extensive consignment markets for dutiable raw materials.
3. The installation of free zones will provide great improvements in port and terminal facilities.
4. Free zones will make up for the inadequacy of a system of bonded warehouses and drawbacks, in so far as industries manufacturing primarily for export and dependent upon dutiable imported supplies are concerned, and in permitting the rehandling, conditioning and reexportation of imports.
5. Free zones obviate the necessity of advancing large sums for bonds and duty payments, the expenses of customs supervision, etc., and provide an opportunity for earnings for American bankers, insurance companies, forwarders, brokers, and others engaged in handling the port's business.
6. Free zones bring about a simplification and reduction of the work of customs administration.

Shipping Activities of The Department of Commerce

By Waldon Fawcett

From the date of its organization, the Department of Commerce has been, logically, the branch of the United States Government closest in contact with maritime affairs and the best positioned of any of the executive departments to render practical aid to shipping interests. The mere circumstance of the grouping within this Department of the Federal institutions devoted to the science of navigation and the practice of commerce would presuppose such a relationship. For the Department of Commerce has served as a clearing house for the Steamboat Inspection Service, the Bureau of Navigation, the Lighthouse Bureau, the Coast and Geodetic Survey and the Bureau of Fisheries.

RISING above the narrow considerations, the technical considerations, if you please, of the specific maritime activities there has always been manifest in the policy of the Department of Commerce an ambition to offer encouragement to shipping development in its larger or broader aspects. Even in the days when it appeared impossible to arouse widespread public sentiment, the voice of the Department of Commerce was persistently raised in behalf of an American merchant marine just as the Department has habitually collected information with respect to ship subsidies in all lands against the time when Congress will decide to adopt a subsidy system in behalf of the American merchant marine and will have need of models on which to pattern its program. Such has been the versatility of effort that it has several times been suggested that the official title should be "Department of Shipping and Commerce."

Constructive as was the work in behalf of shipping that the Commerce Department performed in the past, a new era was ushered in with the appointment of Mr. Herbert Hoover to the position of Secretary of Commerce. Mr. Hoover's varied business experience, culminating in war-time responsibilities that were conducted on the broadest scale, gave him an acute appreciation of the importance to national development of a progressive policy in the provision of the utmost facilities of water-borne commerce. In an effort to stimulate, by every possible means the shipping and shipbuilding activities of the United States the work of the Commerce Department has been expanded along original lines mapped out by Secretary Hoover. Although the extension has been encompassed within the period of a single year and has not yet had opportunity fully to demonstrate its efficacy, it is apparent that the Hoover administration is to reveal in the commercial annex of the Government at Washington new potentialities of encouragement to shipping.

Bureau of Foreign and Domestic Commerce

One of the most notable efforts in behalf of American shipping interests which has characterized the reorganization conducted by Secretary Hoover has had its outcropping in a quarter where such initiative would be least expected. The Bureau of Foreign and Domestic Commerce has always been one of the most important cogs in the commerce machine but it has been devoted, as its title might imply, almost wholly to the promotion of commerce. Shipping problems have been dealt with only incidentally and to the extent that transportation arrangements affected barter and trade in various markets. Under the new status, the chief function of the Bureau is, as of yore, the discovery and exploitation of "trade opportunities" but shipping interests are to have their distinct share in the "information service."

Prior to a year ago, the organization of the Foreign and Domestic Commerce institution was made up principally of two groups of divisions. There were regional divisions such as the Far Eastern and Latin American and there were technical divisions such as those devoted respectively to foreign tariffs, commercial laws and statistics. With the introduction of the Hoover ideals came the addition of a number of "commodity divisions," so-called. A division, in charge of a specialist, is devoted to each of the basic commodities that form the bulwark of American industry, as, for example, iron and steel, lumber, machinery and electrical equipment. With the advent of these commodity sections there came a Division of Transportation and Communication, in charge of Eugene S. Gregg, and in this new agency American shipping interests may be said to have come into their own in so far as it is beneficial to have the aid of an intensely observant "intelligence service."

General and Confidential Information for Shipping Interests

That is what this new division is, essentially, a bureau of information for shipping interests. By means of the organization of United States consular officers posted throughout the world, by means of special commercial agents and field representatives of the Bureau on roving commission, and by means of intensive, systematic perusal of the press of the entire world, this unique institution undertakes to become apprised promptly of any and every development that might by any possibility affect United States shipping interests. Is Belgium reestablishing its shipping connections? Are port improvements authorized in this corner of the world or is a new coaling station instituted in that corner? The transportation division aims to be the first to get the information for American consumption and to get it in full detail. By means of an internal administrative system the shipping information is segregated from the other data on transportation subjects and is available to shipping men. It might be added, too, that the news of shipping developments to which the Transportation Division gives publicity in Commerce Reports and the other publications of the Bureau of Commerce by no means represents the sum total of the garnered knowledge. The shipping annex is obtaining all the while a wealth of confidential information on shipping subjects which, for one reason or another, it is not enabled to print but which will be communicated in confidence to any authenticated American shipping interest that might be affected by the news.

Specific Services Performed by Department

Coincident with this effort to give American shipping men a bird's-eye-view of the world-wide panorama of maritime development Secretary Hoover has drafted the far-flung field organization of the Bureau of Foreign and Domestic Commerce to facilitate by every possible means the movements of American shipping. Cooperation with the Shipping Board has been particularly close and effective. Illustrative of recent effort in this direction it may be cited that, through the intervention of the London office of the Commerce Bureau, the British Ministry of Transport was induced to instruct the Great Western Railway to give better facilities for American shipments. The London branch was also enabled to

hasten the installation of unloading equipment at Fowey to facilitate the quick "turn around" of Shipping Board vessels at that point. On the other hand, it was due largely to representations made by the Near Eastern and Far Eastern Divisions of the Commerce Bureau that the Shipping Board has been brought to a realization of the importance of maintaining adequate service, via direct lines, to Eastern ports.

During the past year or two the Bureau of Foreign Commerce has revealed one form of useful service to American shipping interests which it is to be hoped will not often be invoked but which is of the highest practical value when needed. Reference is made to the reportorial service covering congestion at foreign ports. At Havana, Cuba; Callao, Peru, and other ports where United States vessels were affected by the unprecedented congestion, the representatives of the Commerce Bureau kept constantly in touch with the situation and were enabled by prompt communication by cable to qualify the Department at Washington to give helpful advice to shippers and ship operators. A special committee from the Bureau visited Cuba at the height of the port congestion at Havana. Not only did this visit bring tangible results in relief of the tie-up but it also established an important precedent in justification of business action rather than diplomatic action in the treatment of shipping problems that may involve two or more nations of the western hemisphere. Notable as has been the work performed by the Foreign Commerce Bureau in the recent past Secretary Hoover is ambitious further to extend the efforts in behalf of shipping. For example, he is to seek from Congress funds that will enable the establishment of technical divisions devoted to "Packing for foreign shipment" and other export responsibilities that are integral with shipping routine.

Improvements in Navigation Laws

The Steamboat-Inspection Service is a branch of the Department of Commerce that bids fair to develop, under the general supervision of Secretary Hoover, more discernedly in line with the needs of the shipping community. For one thing, a renewed effort is to be made to secure the amendment of Sections 4433 and 4418 of the Revised Statutes in regard to the working and hydrostatic pressure of boilers. This is an issue which has been raised repeatedly by the manufacturers of boilers and the service has been criticized because of its rules and regulations but the modernizing of these rules has waited upon authority from Congress.

A drive will also be made to bring about the amendment of Section 4472 of the Revised Statutes which governs the transportation of dangerous articles. As now enforced this law is worse than obsolete. It was originally enacted solely to meet conditions induced by the operation of a certain class of vessels on the western rivers of the United States whereas we find it applied today to vessels engaged in offshore trade. If Congress can be induced to take the action that has been recommended, interests engaged in the shipment or transportation of commodities on steamers carrying passengers or on freight vessels would be in a position to know at all times what rules governed the transportation of any dangerous article covered by the code instead of being confronted, as at present, with a formidable amount of red tape. Furthermore, a revision of the law would make it possible to carry on steamers carrying passengers certain commodities that may with safety be carried but which under the present law are entirely prohibited.

Bureau of Navigation Active

The Bureau of Navigation seems to be animated, under the present administration, with something of the same progressive spirit that is manifest in other subsidiaries of the Department of Commerce. Shipping men will rejoice that the new administration is pledged to exert all possible influence to bring about the enactment of the long-awaited and sorely-needed American load line law. It is evident that there cannot be maintained indefinitely the informal arrangement made in 1919 with the authorities of the United Kingdom whereby there is temporary recognition for load lines marked by the American Bureau of Shipping according to the British freeboard tables and rules. The enactment of a load line law would necessitate closer cooperation on the part of the inspection branches of the department with the American Bureau of Shipping and there would, in turn, be a necessity for a small staff of trained ship surveyors in the institution at Washington.

Qualified Experts for Special Services Needed

Eloquent of practical service of the utmost significance to American shipping interests in more ways than one is the aspiration of the Department to create a staff of surveyors similar to that maintained by the British Board of Trade. Such specialists would be available for counsel and decision on questions inseparable from the administration of the navigation laws. And inasmuch as these laws are shortly to be extended and elaborated there will be a proportionately more urgent need for such advisory service. Particularly is there need on Uncle Sam's staff for experts qualified to represent the United States at the important international conferences on safety at sea and kindred subjects which are to be resumed this year.

It will be recalled that the loss of the steamer *Titanic* resulted in an international technical conference that took up such fundamental principles of ship construction as the subdivision of hulls of ocean passenger steamers. The outbreak of the World War postponed the carrying into effect of the international convention that grew out of that conference but the record of the war, particularly in the havoc of submarine destruction, only served to emphasize more strongly the need for the formulation of scientific principles covering this phase of ship construction. To the end of securing an international agreement upon hull construction rules there was an informal meeting last May at which Great Britain, France and the United States were represented. According to the present plan this will shortly be followed by a general conference at which it is hoped that an international agreement will be ratified. To have within the personnel of the Department authorities qualified to represent creditably the United States at this and similar conferences is the immediate ambition of Secretary Hoover and his aids.

Regulation of Radio Communication

Governmental supervision of radio communication is another responsibility integral to shipping with respect to which the present administration at the Department of Commerce has views distinctly at variance with some of the ideals that have prevailed in the past. It is admitted that the regulation of radio communication has become a matter of increasing intricacy and difficulty and that present regulations in the United States do not meet requirements. However, the Department's attitude is that it would be a mistake to press for action by Congress in revision of the regulations applicable to this country alone when there is prospect of revision at an early date of the international regulation of radio communications, in accordance with the project launched in the autumn of 1920 in which there was joint action by representatives of the United States, Great Britain, France, Italy and Japan.

Disintegration of the United States Coast and Geodetic Survey, with attendant loss to the shipping interests of the country, is the most disquieting feature of Secretary Hoover's inventory of the Department of which he has taken charge so energetically. A new building is needed as a home, if this Bureau is to function to the fullest extent, but even more serious than this lack is the low level of salaries obtaining in the Survey which is operating to drive to private fields of employment the experts upon whom the nation has been

(*Continued on page* 90.)

Developments in Marine Insurance

Retrospect of 1921—Ship Lien Issue— Marine Policy Not Valued—Model Bill Passes—Lying-up Returns

By "Bordereaux"

WHEN the final company reports are all in it is not likely that the year 1921 will be found to occupy a particularly impressive place in the history of the business. Enough is in evidence to warrant giving it a very modest ranking indeed. Few marine insurance writers made any money at all last year; and where there was a margin of profit it was narrow to the vanishing line.

One of the reasons is because 1921 was a year of readjustment, the companies groping their way back to normal and familiar conditions; and in such abnormal circumstances it would take a confirmed optimist to anticipate any great degree of money-making. The "war babies" have been shyly withdrawing, and several of the weaker sisters have followed their wise lead. The experienced, old-time offices are still on the job and will doubtless continue to function as actively as ever.

There have been encouraging developments in 1921, and chief of these has been the disposition to get together—something traditionally lacking hitherto among American marine underwriters. This has had its manifestations in the development of the American Marine Insurance Syndicates, the launching of the United States Salvage Association, the merger of the National Board of Marine Underwriters with the Board of Underwriters of New York to the conservation of much expense and effort, and the fine co-operative spirit shown in backing the important marine insurance Federal movements—such as the Load Line Bill, the Model Bill, and the fight to amend the Harter Act. Unquestionably the Syndicates have helped immensely to stabilize the hull insurance market, and their writings have been extensive.

The decline in trade has restricted premium receipts from cargo writings, and this has been still further accentuated by the steady fall in values. Losses in the cargo line have been both numerous and heavy, due to the disposition of foreign consignees to decline deliveries in the face of an adverse market.

So much for 1921. That is past and gone, and insurance men are more interested in what 1922 gives promise of handing them. And, from present indications, the outlook is none too bright, largely because of the intensity of competition and the tendency to cut rates. Americans are charging this condition to British eagerness for business over here. The British insurance market is notoriously top-heavy, as a result of war expansion; and preferential rates have carried to the other side several of our most desirable fleets and numerous cargo lines of exceptional attractiveness. This unsettled condition inclines some of our most sagacious underwriters to anticipate two or three years of hard work to hold business, along with a still more slender margin of profit.

Ship Lien Issue Settled

THE United States Supreme Court recently passed upon a legal point involving between twenty and thirty million dollars, the question being one of liability by privately owned vessels for damages inflicted by them while they were still under Government control. It is a matter that vitally interests the underwriter. It is estimated that there are between three hundred and three hundred and fifty cases of this character pending throughout the country, and practically all for collision damages sustained by privately-owned vessels while the latter were still being operated by the Government. The claimants contend that a lien attached as soon as the collision occurred, and that although these liens were not enforceable because of the fact that the Government had not consented to be sued, nevertheless they became enforceable the moment the vessel passed into other than Government hands. The Supreme Court sustained the contention of the Government that the lien never came into existence because the Government was immune from liability for a tort and that, as this was a tort, no liability was attached to that vessel that could pass when the vessel was restored to its owners from whom it was requisitioned.

Marine Policy Not Valued

ON the issue that a marine contract is not necessarily a valued policy, the United States District Court, S.D., New York, recently found for the libelant in an admiralty suit. In his decision Judge Learned Hand held that in a contract of marine insurance on a particular cargo for a particular voyage, effected by a binder incorporating by reference the New York lighterage form, the insertion of the words "valued at sum insured" does not change the normal character of the policy as a contract of indemnity under which the insured in case of loss is entitled to recover only the actual value of the property lost. The court observed that it is the practice in foreign hull insurance to take out true valued policies, but that no such practice exists in domestic insurance, either hull or cargo. When the parties do not take out such insurance, if the valuation be not fraudulent, both sides are bound. It was objected by the court that the language ought to be clearer when the libelant seeks to change the policy from its express and usual meaning—i. e., as a contract of indemnity—to a contract to pay a fixed sum in the event of loss.

Another important point was that the binder was upon this cargo only for this particular voyage, though its duration was uncertain. It had also to be remembered that the assured drew up the binder. It was held that the phrase "valued at sum insured" referred to the coinsurance clause in the policy and did not change the normal, and expressly agreed, character of the policy as a contract of indemnity.

Barge Canal Writings

WITH the closing of navigation in the New York State Barge Canal, the underwriters viewed their season's accounts with rueful countenances. Briefly, they lost money on their operations. Numerous strandings placed the balance on the wrong side of the ledger. Considerable disappointment was experienced with respect to the unexpectedly small amount of tonnage employed in canal shipments.

Loose Phrases Tabooed

CONSERVATIVE American underwriters have been gratified to learn from a copy of a letter written by the Institute of London Underwriters to similar organizations in other parts of the world that stringent action is being taken by that body to correct the use of loose phrases in insurance policies. The letter lays particular stress on the

term "all risks," and points out that due to interpretation by the courts of this phrase in accordance with its liberal meaning rather than in the light of its insurance significance underwriters are being held for all loss of whatever nature to the goods insured. Conservative underwriters in America have consistently refused to follow Lloyd's lead in the use of this and similarly loose phrased clauses, and it is a satisfaction to them to note that their stand is at last vindicated.

"Model Bill" Passes the Senate

MUCH gratification is felt by insurance men over the ease with which the much-mentioned "Model Bill" passed the United States Senate, and they are convinced that the identical House measure will have no less favorable an experience. Although the bill applies only to the District of Columbia it is designed to constitute a working basis for similar legislation in many if not all of the individual States. It clears the way for American underwriters being placed on a parity with their foreign competitors by the removal of legislative obstacles which now stand in their way and with which the underwriters of other nations are not obliged to contend.

Shipments on Cast-aways Are Total Losses

IT is universally admitted that many vessels are being deliberately sunk, and have been for the past eighteen months, in order that their owners may take advantage of the high valuation under which they were insured. In all of these deplorable instances the "innocent bystander" has been the shipper. His plight is indeed a sorry one, for it has been shown, over and over, that he cannot collect any claim on his insurance policies, nor can he obtain satisfaction from the party to whom he should naturally have recourse—the shipowner. The law is rigid on the point that barratry, in which the shipowner participates, deprives him of the protection of his policy, and the shipper is no less deprived of his right to insurance recovery. He cannot hold the shipowner liable when it is shown that the latter was a party to the fraud. Marine policies cover certain definite perils, but casting-away is not one of them. Nor can underwriters be expected to create the deplorable precedent of paying losses, however arising, which are not caused by perils insured against. The only course for the shipper to take is to pay closer attention to the character of the shipowners with whom he entrusts his property.

Lying-up Returns

MORE or less trouble is reported from England because of the settlement of lying-up returns when the period during which the vessel was laid up is broken by the cancellation of the policy in order that cheaper insurance might be effected. It is contended by many underwriters that under such circumstances the proportion of the return attaching to each policy is not collectible. It is an issue that should not be raised at all. When underwriters permit an owner to cancel his policy and to replace it by a cheaper one they thereby place him in the same position as if the policy had expired in the normal way to be succeeded by another one. It is customary to allow lying-up returns when the period for which they are collected overlaps on succeeding policies, and the fact that a policy has expired through cancellation and not exhaustion does not alter the position in the least. Again, the amount at stake on these overlapping returns must be minute compared with the amount that underwriters have sacrificed by consenting to the cancellation of policies and the substitution of others at cheaper rates. London underwriters are expressing the hope that their confreres as a whole will not countenance the attitude in this matter taken by some of them.

Change in Syndicate Officers

LAWRENCE J. BRENGLE has been appointed active manager of the recently organized United States Salvage Association—which is the operating agent of Syndicate "A" of the American Marine Insurance Syndicates —in succession to Charles R. Page, who recently resigned to engage in marine insurance. John H. Trowbridge, chief clerk of the Syndicates, becomes assistant manager. Gomer H. Rees has resigned as secretary of the Salvage Association, and Mr. Page becomes a manager of Syndicate "A." Mr. Brengle has been the underwriter of Syndicates "B" and "C," and will continue to discharge those duties in connection with his new ones. He brings to his Salvage Association work a wide experience in the handling of wrecked and damaged vessels on both the Atlantic and Pacific coasts. He is a Philadelphian by birth, and has spent ten years in the extensive operations of the large brokerage firm of Johnson & Higgins. Mr. Trowbridge was at one time secretary of the Insurance Advisory Committee of the Food Administration Grain Corporation, and has been with the Syndicates for more than a year.

Losses Caused by Stowaways

ARE marine underwriters liable for damage or loss caused by stowaways? This rather singular question is not without point at this time, in view of a recent heavy claim submitted to New York insurers arising out of a fire in a cotton cargo directly traceable to stowaways lighting a match while lying concealed among the bales in the hold. Despite the fact that a marine insurance policy specifically states that it covers against fire, still there is a question as to the liability of underwriters for such a loss as this. It would seem that, if a loss by fire is caused by stowaways, as fire is one of the insured perils, the underwriters are liable unless their policies contain a clause specifically excluding loss by stowaways, or words to that intent. When a fire is caused by the negligence of the crew the underwriter is liable simply because fire is an insured peril, and the causes responsible for the fire are immaterial, the doctrine of proximate cause not being involved.

Those who maintain that the underwriters are not liable for such a fire as this stowaway one base their contention on the ground that the fundamental principle of marine insurance was created for the purpose of covering fortuitous losses and that a fortuitous loss does not contemplate the careless or intentional act of a party who bears no relationship to the venture. They insist that specific exclusion is not necessary. Under the American law the carrier is doubtless liable for this stowaway loss, but that fact does not of itself excuse the underwriters from their responsibility.

Shipping Activities of the Department of Commerce

(*Continued from page* 88.)

dependent for the fidelity of its nautical charts, tide tables, current, magnetic and triangulation data. Handicapped as it is, the Coast and Geodetic Survey is prosecuting important work; for example, a beginning has been made in securance of observations in New York harbor, the ambition being to provide a systematic tidal and current survey that will aid shipping men by furnishing more accurate current predictions for the docking of large vessels and that will also be of use to the engineers charged with the development at New York of what will be the greatest harbor in the world.

Shipping and Shipbuilding in Great Britain

Vessels Selling at Pre-War Prices — Future of British Shipyards Uncertain—Outlook for Ship Repairing Gloomy

By W. H. Wendon

SIGNS are not wanting that the shipping trade of Great Britain may in the early future take a turn for the better. No surer indication could be found than in the fact that more than one of the country's most astute owners—men who had the good sense to dispose of their fleets at the enormous values current during the late boom—are re-entering the shipowning world and, as compared with the prices at which they sold the boats, are re-acquiring these or purchasing others at something approaching pre-war prices. The course adopted by Sir Walter Runciman, for example, is full of significance. When Sir Walter Runciman sold his well-known "Moor" fleet to the ill-fated Western Counties Company, there were many in the shipping world who were amazed at his action, for at that time—February, 1920—there were hopes that the fabulous values then current would ascend yet higher. But, as is now only too well known, the slump set in with remarkable rapidity, justifying the foresight of Sir Walter Runciman and a few—but very few—others.

But that is a matter of history. What concerns us now is that, as I have hinted, the older shipowners are coming into the tonnage market again, no fewer than six new 9,000- to 11,000-ton deadweight steamers, in addition to older boats, having been acquired by Sir Walter Runciman on behalf of his re-constituted Moor Line. It is particularly noteworthy that these new vessels, which have been constructed by Messrs. William Doxford & Sons, Sunderland, are similar to those which before the war realized sums ranging between £81,000 and £95,000. These figures compare with the £8 per ton deadweight just paid by Sir Walter Runciman, thus exemplifying the tendency to pre-war quotations.

A further recent instance of a shipowner having the courage of his convictions to the extent of purchasing a large fleet is that of Mr. D. R. Llewellyn, of Cardiff, who has become the owner of the Maindy fleet, the method of acquisition being purchase by auction, following seizure by the bank owing to the Maindy Company being unable to meet its obligations.

Fluctuations in Shipping Values

It is not without interest at this juncture to trace the fluctuations in value of, say, a 7,500-ton deadweight cargo carrier. Prior to the Great War the highest price obtained for a vessel of this description was the then huge sum of £60,630, which was obtained towards the end of 1900. With the release of tonnage after the South African war, however, values immediately dropped and by the end of June in 1901 only £49,250 was obtainable.

The fluctuations in the ensuing ten or eleven years are too numerous to describe within the space alloted to this summary. Suffice it, therefore, that by November, 1912, £58,000 was the approximate value placed on this size and type of vessel. From that date until just before the opening of hostilities in 1914 there was a consistent decline in value, the final quotation recorded prior to the war being £45,000. Had the war not intervened, there is excellent ground for believing that values would have dropped still further, and, in the opinion of those competent to judge, the record low figure of 1908, namely, £36,000, would have been attained. But the gods decreed otherwise, the record high figure of £34 10s. per ton deadweight, equivalent to £258,750, being recorded in March, 1920. To-day the best that can be obtained for the type and size of boat under review—and, as already stated, for 9,000- and 11,000-tonners—is £8 per ton on the deadweight, or less than one-fourth of the value current two years ago.

Possibilites of the Future

Now that the new year is fairly launched, it should not be without value to turn for a moment to what our leading shipowners, and those engaged in allied industries, consider to be the possibilities and probabilities of the future. One of the foremost men interested in all branches of the shipping trade—that is to say, ship owning, construction, repairing and chartering—is Mr. J. C. Gould, Member of Parliament, of Cardiff. Mr. Gould, in common with most business men, breathes a sigh of relief at the passing of 1921, which period he rightly describes as one of catastrophe as regards trade and commerce, the slump in its unparalleled suddenness sweeping many firms off their feet and causing widespread unemployment. As Mr. Gould points out it was generally anticipated that the slump would be a gradual one, and would be accompanied by a decline from the abnormal values at which goods and services had soared.

Too Little Business Rather Than Too Many Vessels

But the apparent excess of shipping tonnage, in Mr. Gould's view, is purely artificial. There are, he thinks, not too many vessels on the water—rather, that it might be successfully argued that the depression lies in the fact that there is not enough business to employ the present vessels available. This line of reasoning, as I am sure Mr. Gould would be the first to admit, is open to strong criticism, but at all events it is evidently Mr. Gould's considered opinion, and therefore is entitled to be weighed in the balance, even though it eventually be found wanting. The basis for Mr. Gould's contention is this: By eliminating tankers, passenger liners and intermediate vessels, he arrives at the conclusion that the comparative excess of tonnage is very small. To which, I might add, there is the undoubted presence of large numbers of obsolete and semi-obsolete merchant vessels.

In conclusion, while Mr. Gould does not think things are to be much better for some time to come, he does not despair of the future. He points to the better spirit in trade unionism to-day than there has been in the past and, with the saving of disastrous losses of time consequent on industrial disputes (according to a German statistician, Britain since the Armistice has lost 73½ million out of 90½ million working days lost in the whole world) there is little doubt that brighter days are in front of the British shipping and allied industries.

Prospects of British Shipyards

As to the prospects of British shipyards, none could speak with greater knowledge than Mr. James Lithgow, the president of the Shipbuilding Employers' Federation. Mr. Lithgow traces the present slump to the abnormal prosperity which affected our industrial community in both a material and a moral sense. The material standpoint may be said to be that productive facilities have been improved and extended, and the economics possible to be effected will be discernible when production has a chance to get going. The

moral standpoint may be summed up, that present-day workers, and particularly the younger generation, have the fixed idea that the shortest possible day's work should be given in exchange for the maximum wage obtainable. That, however, is, let us hope, a passing phase.

To return to Mr. Lithgow's analysis, it is of no little interest to note that he views "mass production," either in the shipbuilding industry or any other sphere, as beneficial from the point of view of opening up possibilities for producing goods at a price that a greater number of people can pay. He instances the fact that, if a Ford motor car cost as much as a Rolls Royce, there would be no owners of Fords, but, on the other hand, there would be far fewer owners of motor cars. In the same way, Mr. Lithgow records "payment by results" as being of value to industry in ensuring the largest reward to those who exert extra effort, and in reducing at the same time the total cost of the work performed. Mr. Lithgow is especially serious when touching on the question of foreign competition. Suggestions that this is is of no consequence, and that British shipbuilding can flourish without foreign orders, show, as he points out, ignorance of the facts.

Shipbuilding Depends on Rise in Freight Rates

From a general point of view, the prospects of the British shipbuilding industry are, to say the least, uncertain. The trade, of course, benefits by a rise in rates of freight, for it is then that shipowners consider the advisability of laying down fresh tonnage. But such a fortunate occurrence does not come about until some time after the first signs of a shipowning revival are apparent and, in the meantime, the builder has to bide his time.

But there is another aspect. Throughout the British Isles, in common with other parts of the world, there are large numbers of ships, some nearly completed, others scarcely started. Work on these boats has been under suspension for periods reaching in some cases eighteen months. It is on the cards, therefore, that, with brighter chartering prospects, owners may instruct builders to carry on with construction of their partially finished vessels. Such has, indeed, already been the case in a few notable instances, particularly in regard to liners, where the slump is not so grave.

Ship Repairing

The outlook in the ship repairing industry is as gloomy as, if not gloomier than, that existing on the whole in the "parent" trades—shipbuilding and shipowning. According to one authority, in marked contrast to the comparatively bright outlook at this time last year, the conditions existing in the ship repairing trade at the present time are dismal in the extreme. Indeed, no one engaged in the industry can recall such a hopelessly black prospect. It is generally regarded as being, without doubt, the worst time ever known in the industry.

Locks in Industrial Canal at New Orleans, the Second Largest Inland Waterway Scheme in America, Nearing Completion

Motorship Californian Fitting Out at Merchant Shipyard

New American Motorships Californian and Missourian

American-Hawaiian Vessels the First Large Motorships to Be Specially Designed and Built in Their Entirety in the United States

THE *Californian* and *Missourian* mark an era in American shipping and shipbuilding by virtue of the facts that they are the first large motorships specially designed and constructed in the United States and that the machinery is the first of its kind to be constructed exclusively in an American shipyard.

The hulls for the vessels were constructed at the yard of the Merchant Shipbuilding Corporation, Chester, Pa., and the machinery was built and installed by the William Cramp & Sons Ship & Engine Building Company, Philadelphia, Pa., who are licensees for the Burmeister & Wain marine Diesel engines.

Much credit is due the officials of the American-Hawaiian Line for their initiative and judgment in adding these modern vessels to their fleet.

The vessels, which take their names from two former American-Hawaiian steamers sunk by submarines during the war, are of the flush deck type with officers' and crews' accommodations and bridge located together amidship, as is generally characteristic of vessels belonging to this steamship company. This arrangement has much to be commended as it permits the maximum number of cargo hatches and winches to be employed for rapid loading and unloading of cargo and also places the bridge in an advantageous position for the captain in handling the vessel when coming alongside docks.

The main and auxiliary machinery is identical in type to that of the motorship *William Penn,* the machinery for which was installed by the William Cramp & Sons Ship & Engine Building Company in a hull built at the Gloucester Plant of the Pusey & Jones Company and afterwards towed to the Cramp yard for machinery installation. There is a difference, however, in the number of auxiliary engines, the American-Hawaiian vessels having four instead of three, due to the larger number of winches employed.

The motors and generators within the engine room were supplied by the Diehl Electric Manufacturing Company to special requirements. The motors for driving the pumps have ball bearings and are totally enclosed.

The machinery has been built to conform to the requirements of Lloyd's Register of Shipping.

Cargo Handling Machinery

The cargo handling machinery for these ships has been most carefully selected and consists of fourteen double-geared winches and two Shepard Crane & Hoist Company's winches on each ship. The fourteen winches for the *Californian* were manufactured by the American Engineering Company and the winches for the *Missourian* were made by the Maine Electric Company. Each winch is driven by a thirty horsepower electric motor of the "Mill" type. The motors and the controllers for the *Californian* were supplied by the Westinghouse Electric and Manufacturing Company. Those for the *Missourian* were furnished by the General Electric Company.

Main Engines

The main engines consist of two Cramp-Burmeister & Wain four cycle marine Diesel engines, of the crosshead type and having six cylinders each with a bore of 29⅛ inches and a stroke of 45¼ inches. Each engine is capable of developing continuously 2,250 indicated horsepower when turning 115 revolutions per minute. They are of the enclosed type and arranged for forced lubrication throughout. To the forward end of each engine is fitted a three-stage compressor for supplying injection air of 850 pounds pressure.

Auxiliary Machinery

The auxiliary engines are of the typical Burmeister & Wain four cycle design, having two cylinders each. They are rated as 100 brake horsepower each, and are direct connected to 65 kilowatt direct current generators running at 300 revolutions per minute.

Three centrifugal cooling water pumps, arranged along the forward end of the engine room, supply salt water cooling to the main and auxiliary engines and maneuvering compressor, one being usually all that is required, with the other two as standbys. The water to the main engines divides on passing through the jackets of the compressors, part going

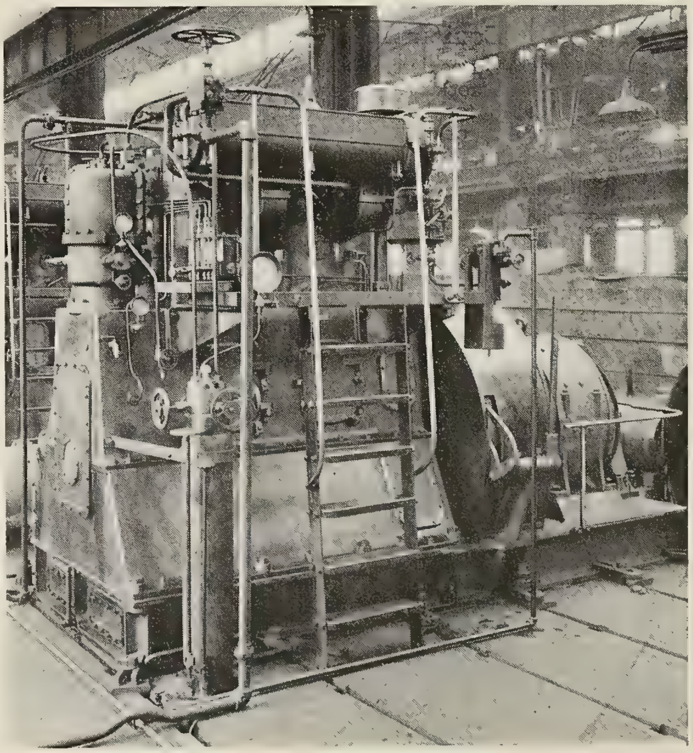
Section Through Machinery Space of Motorships Californian and Missourian

to cooling the thrust bearings, guides and pistons and part to the fresh water cooler from which it is discharged overboard by way of the jackets surrounding the exhaust manifolds. A fresh water closed cooling system is employed for the main engine jackets and cylinder covers, which arrangement has been recently adopted for deep draft vessels to guard against getting mud or sand into the system when navigating in rivers or passing through shallow waters. The circulating pump for circulating the fresh cooling water is located on top of the fresh water cooler.

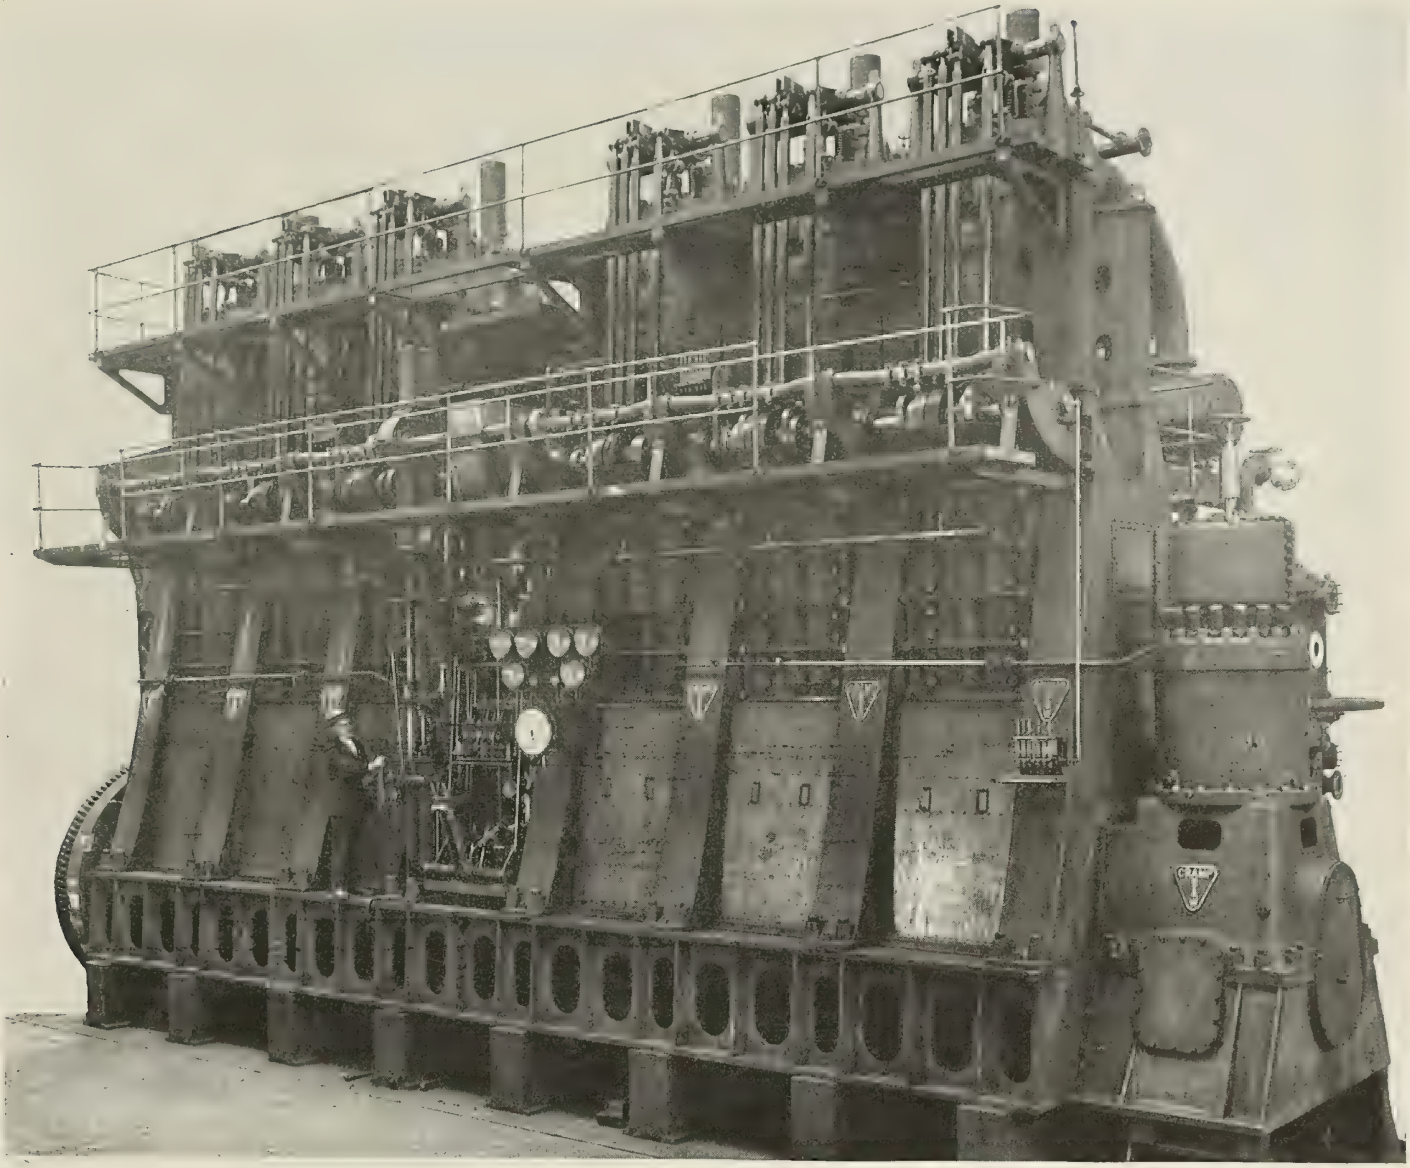
Two sets of lubricating oil pumps are provided for supplying oil under pressure to the main engines, one set being in operation at a time. Each consists of two gear type pumps driven by a common motor and so arranged that each supplies oil independently to one of the engines. The oil drains from the main engines to two separate settling tanks, built into the double bottom of the ship, from which the pumps draw, discharging through strainers to the pressure lubricating systems.

A fuel oil transfer pump, also of the gear type, is used for general oil transfer purposes and for pumping up the daily supply tanks. These latter, which in addition act as settling tanks, are placed on a platform on the forward engine room bulkhead and are of sufficient capacity each for 12 hours running. A small tank is used for a lighter grade of oil for starting up and closing down the auxiliary engines should the main supply be fairly heavy.

A two-stage air compressor, driven by a 120 horsepower motor, and operated when maneuvering is to be done, delivers air at 350 pounds pressure to the starting air receivers located on the port and starboard sides. This compressor also takes the place of a reserve compressor should one of the main engine compressors be out of commission. In such an event the high pressure cylinder of the main engine compressor not disabled draws air from the starting air system and supplies injection air to both engines. The usual losses



One of the Auxiliary Engines



One of the Main Diesel Propelling Engines of the New American Motorships

in maneuvering air when at sea are made up by air taken from the main engine compressors. There is also a small steam driven compressor for pumping up one of the auxiliary engine air bottles when the vessel is new, or should all air on board be lost accidentally.

Two three-throw plunger pumps are for sanitary and fire, general bilge service and for removing the piston cooling water which is dropped into a well in the engine bilge after being discharged from the pistons. One pump is kept as a spare, except in case of fire, when both are employed.

The ballast pump is of the wing type with a capacity of 150 tons per hour.

A small donkey boiler of the fire tube type with 400 square feet of heating surface is installed in the thrust recess for furnishing steam for heating, for operating the small reserve compressor and for fire extinguishing purposes. A CO_2 smothering system is also installed and arranged to work in common with the steam system.

A motor generator set of 20 kilowatts capacity changes the 220 volts to 110 volts for lighting purposes. A 15-kilowatt kerosene engine driven lighting set is installed on the main deck as a reserve lighting set and for operating in port when it is desired to close down the engine room completely.

Provision is made in the silencer house for heating salt and fresh water for sanitary purposes from the exhaust gases from the main engines.

Weight of Machinery

The total weight of the two main engines with flywheel, attached piping, grating and exhaust manifolds is 543 tons. The total weight of machinery within the engine room, including shafting, etc., and deck silencers, with water but excluding hull engineering piping, etc., is 932 tons.

The contract speed of the vessels is 11.5 knots loaded, though it is anticipated that 12 knots will easily be made, which is to be assumed from the performance of similar sized foreign vessels having similar block coefficients and the same size engines.

No effort has been spared in obtaining for these ships the best in workmanship and material, and in the selection of auxiliaries, so that when they go into service it is expected that they will rank with the best freighters in the world in economy and reliability.

The size and tonnage of these motorships are the outstanding features for economical service and they are considered the most acceptable type for the establishment and maintenance of long distance voyages for combined cargo-passenger trade routes.

It is encouraging to note that American shipowners are beginning to appreciate the economy of motorships for long voyages and are taking steps to place the American merchant marine in a position to meet foreign competition in this respect.

The Motor Liner Domala, of 11,000 Tons Deadweight Carrying Capacity and 13¾ Knots Speed

Motor Passenger Liner Domala

First Oil Engined Vessel Specially Designed for Carrying Passengers—Radius of Action Over 13,000 Miles

By Our Special London Correspondent

ALTHOUGH the motor ship *Aba,* which sailed on her maiden voyage in November, was the first passenger liner equipped with internal combustion engines, she was not originally constructed for this purpose and was, in effect, a converted cargo ship. The *Domala,* however, which left London on December 30 for her first trip, was designed in the first instance as a passenger liner. As she is the first ship built for the British India Steam Navigation Company, her completion has aroused enormous interest. This firm owns some 50 steamers, and is affiliated with the Peninsular and Oriental Steam Navigation Company. It may therefore reasonably be anticipated that, if the *Domala* proves successful in service, she will be followed by still larger motor mail liners on the Peninsular and Oriental service between London and India.

Popular Line With Passengers and Shippers

The *Domala,* except for her machinery, is similar in design and appearance to a number of steamers built for the same owners. These have always proved extremely popular vessels, both with passengers and shippers, as the voyage from London to Bombay takes only a few days longer than the mail steamer, while the price is £10 lower. Passenger accommodation is all amidships, comprising cabins for 41 second class and 85 first class passengers, although arrangements are made by which some of the two berthed first class rooms can be turned into three berthed second class, if desired, increasing the total passenger accommodation to about 140. The engine room is arranged amidships and it is a proof of the quietness and absence of vibration of modern Diesel machinery that the passenger accommodation is all above the machinery, which would not have been allowable were vibration or noise excessive.

Larger Deadweight Carrying Capacity

The total length of the engine room exclusive of the thrust recess is 56 feet and, although, owing to the adoption of the four cycle system, the engines are large and heavy, the overall length occupied is less than that required in a corresponding reciprocating steam engined vessel including the boilers and cross bunkers. The actual machinery weighs approximately the same as a steam plant of similar power, but a considerable additional space is available for cargo, as the fuel oil is carried in tanks in the double bottom, forward of the engine room. For a given radius of action (which is over 13,000 miles in the case of the *Domala*) the weight of oil required is one quarter of that in a coal fired steamer, so that the deadweight capacity of the motorship is larger.

Electro Hydraulic Winches

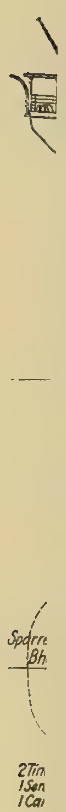
Of the six holds, varying in length from 49 feet 6 inches to 60 feet 6 inches, three are arranged forward, and three aft of the engine room, served by 12 three-ton winches of the electro hydraulic type. Winches of this class are very uncommon, the advantage claimed being that any speed of lifting is possible from the maximum to a "creep," and that the control is much better than is possible with electric winches provided with ordinary contactor switches. They are of the Williams Janney design, the same principle that is now frequently adopted for electric hydraulic steering gears. It involves a hydraulic pump which is driven by an electric motor. The whole of the control of the winch is effected on the pump itself so that the motor operates continuously.

These winches are more expensive to install than the direct gear driven type but the manufacturers state that the cost of upkeep is less, the consumption smaller and they are simpler to manipulate by the natives who operate the cargo handling appliances on the eastern run. There are six hatches each provided with two winches.

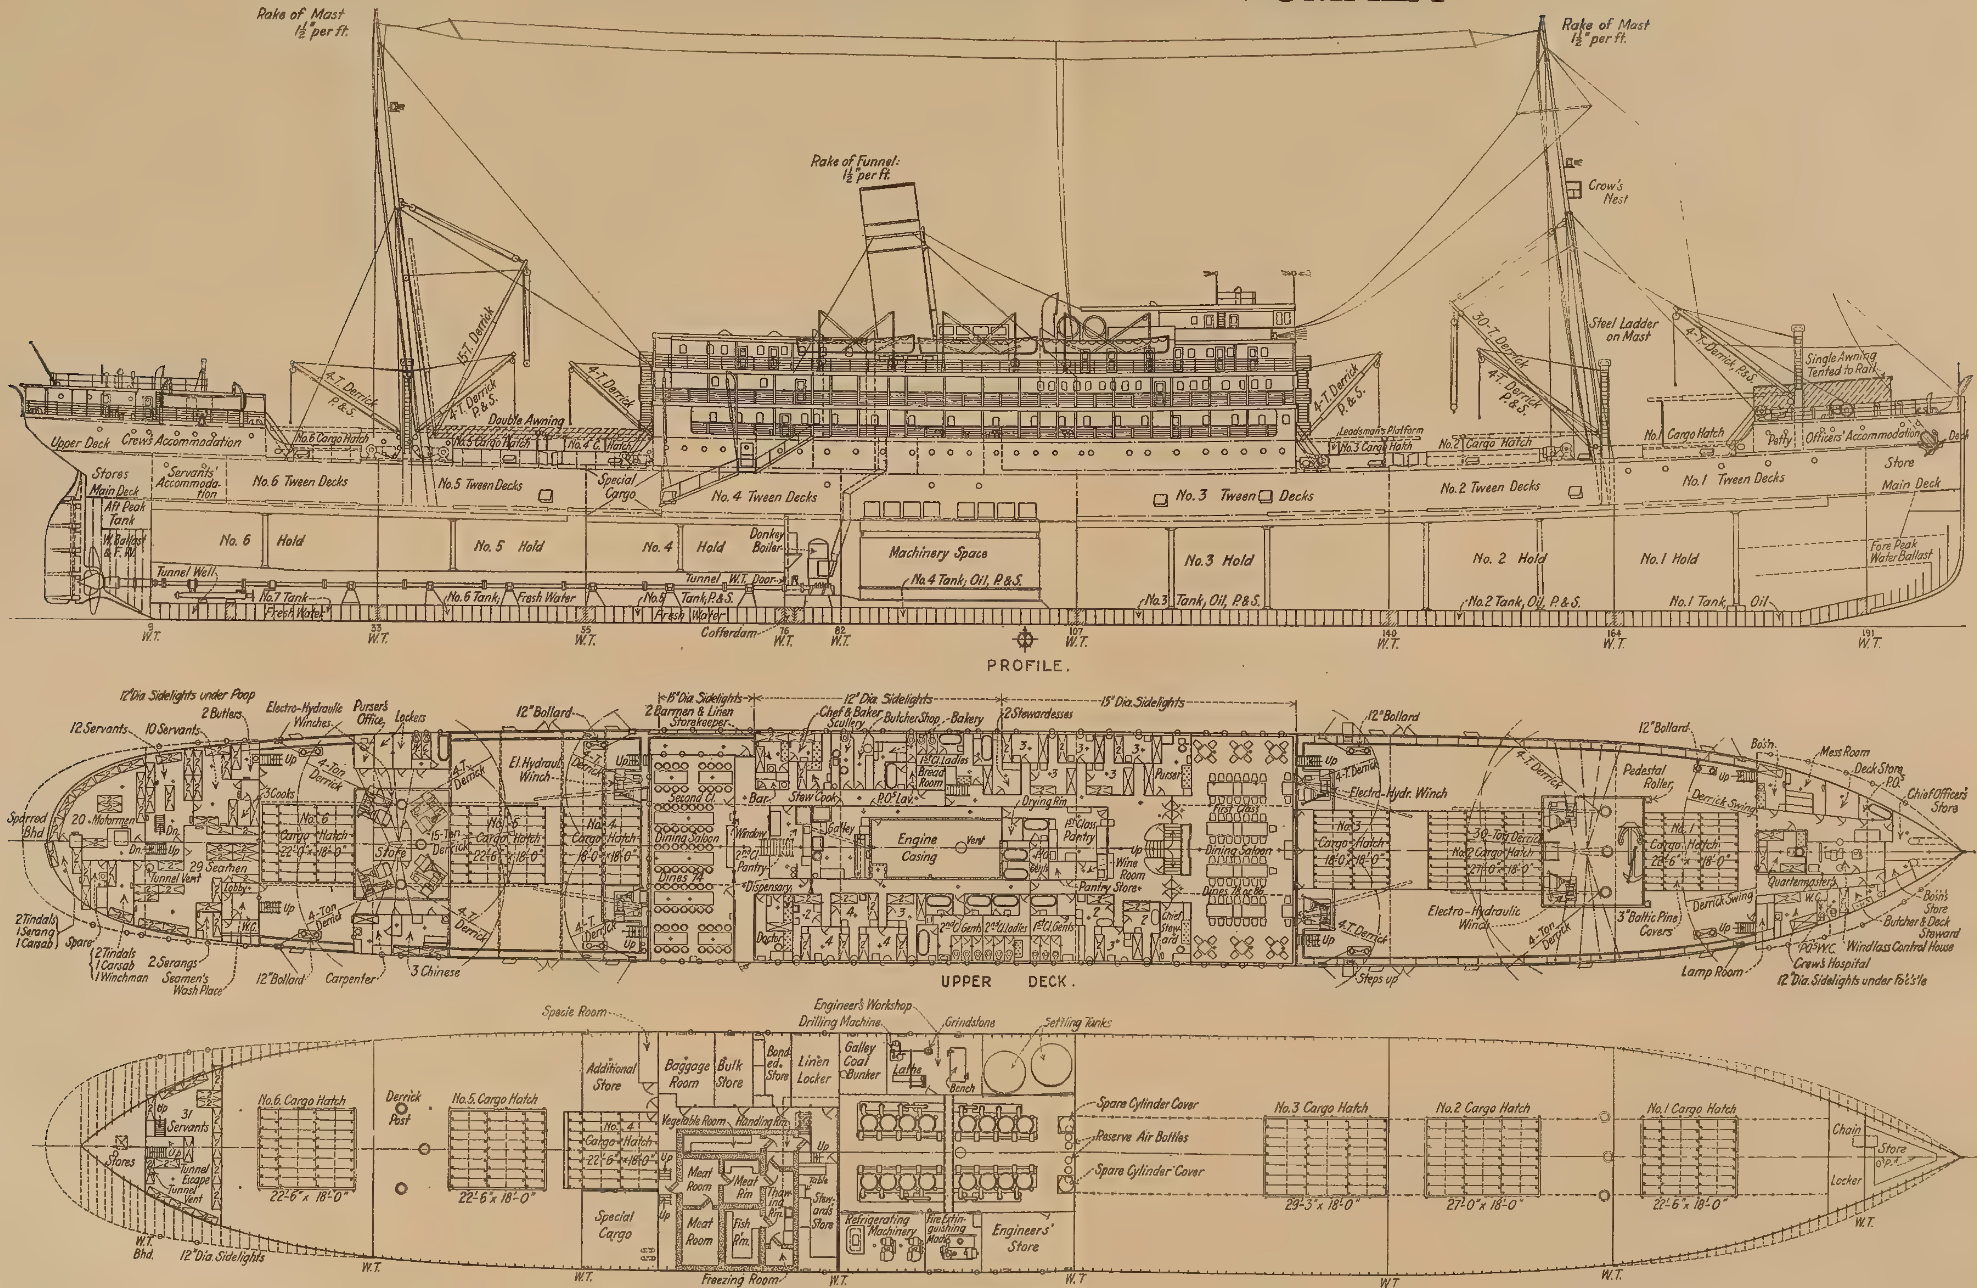
Construction of Hull

The hull of the *Domala* was built by Barclay Curle and Company, Limited, on the Clyde, and has the following dimensions: Length overall, 465 feet; length between per-

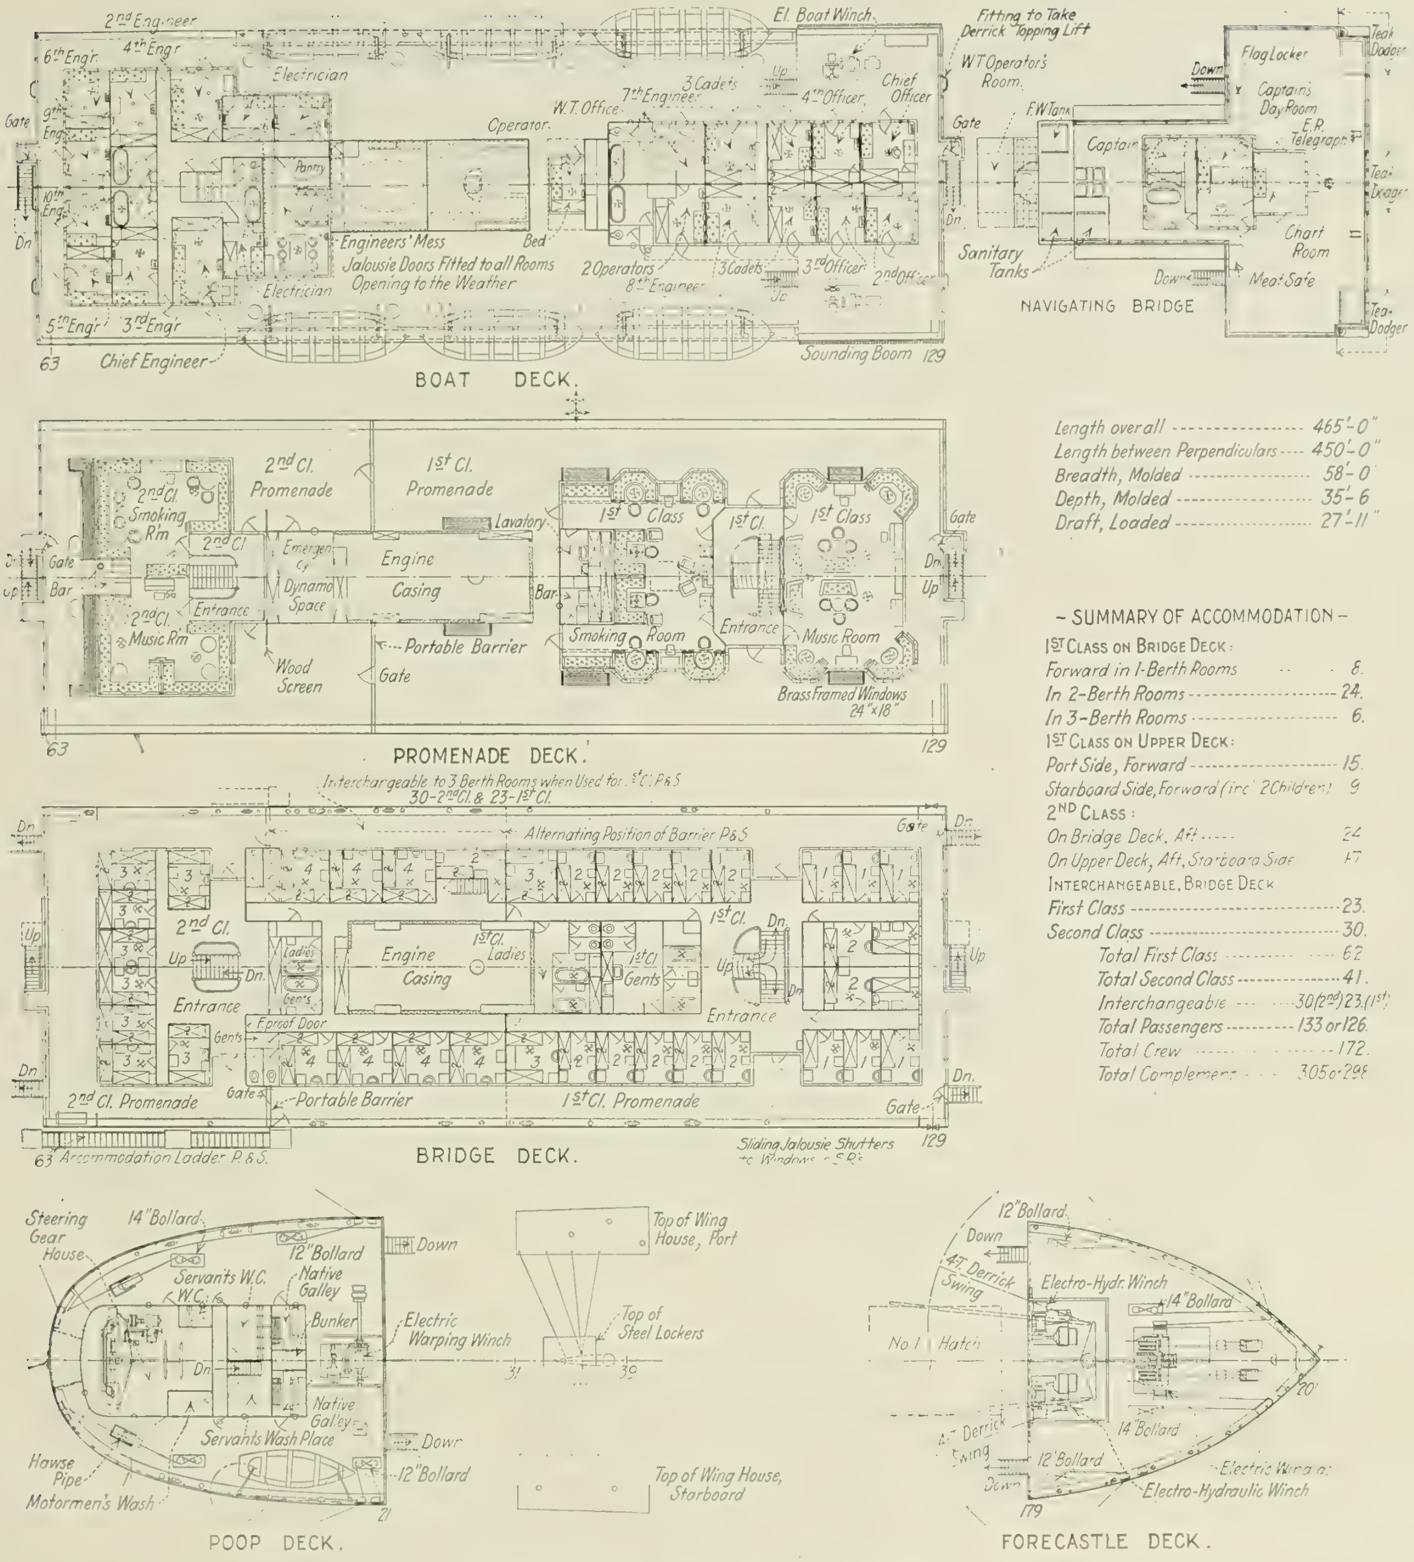
MAF



MOTOR PASSENGER LINER DOMALA



Profile and Deck Plans



Upper Deck Plans of Motorship Domala

pendiculars, 450 feet; breadth molded, 58 feet; depth molded, 35 feet 6 inches; draft, 27 feet 11 inches. The gross tonnage is just under 9,000 and the deadweight capacity about 11,000 tons.

A large proportion of the crew, which totals 172 people, is composed of natives, quartered in the poop, while the European petty officers have cabins in the forecastle. Lord Inchcape who is chairman of the British India Steam Navigation Company, holds strongly to the view that engineers and deck officers should have the best possible accommodation and moreover that they should be located on the same deck. In the *Domala,* therefore, both the engineers and the navigating officers are berthed on the boat deck, the former at the after end and the latter forward, a separate room being provided for each deck officer. It is to be noted that by this system, the engineers and deck officers have a large space for recreation purposes, exclusive of the passenger deck.

Main Deck Arrangement

On the main deck, aft of the engine room, are various refrigerated chambers cooled on the carbon dioxide system and, in addition, the baggage room, linen locker and stores for other purposes. On the upper deck immediately above are a number of first and second class cabins, with the first

class dining saloon at one end and that for the second class at the other. In both cases, seating accommodation is provided for more than the full complement of passengers, mainly at small tables.

All of the cabins, on this and the other decks, are provided with a port hole. An examination of the plans will show that in the case of the interior cabin this has been carried out in a very ingenious manner by leaving a passageway between the two outer cabins. In this way, a certain amount of space is lost but there is undoubtedly an overwhelming advantage in its favor. The system was introduced by Lord Inchcape and a somewhat similar method is adopted on certain other British passenger liners.

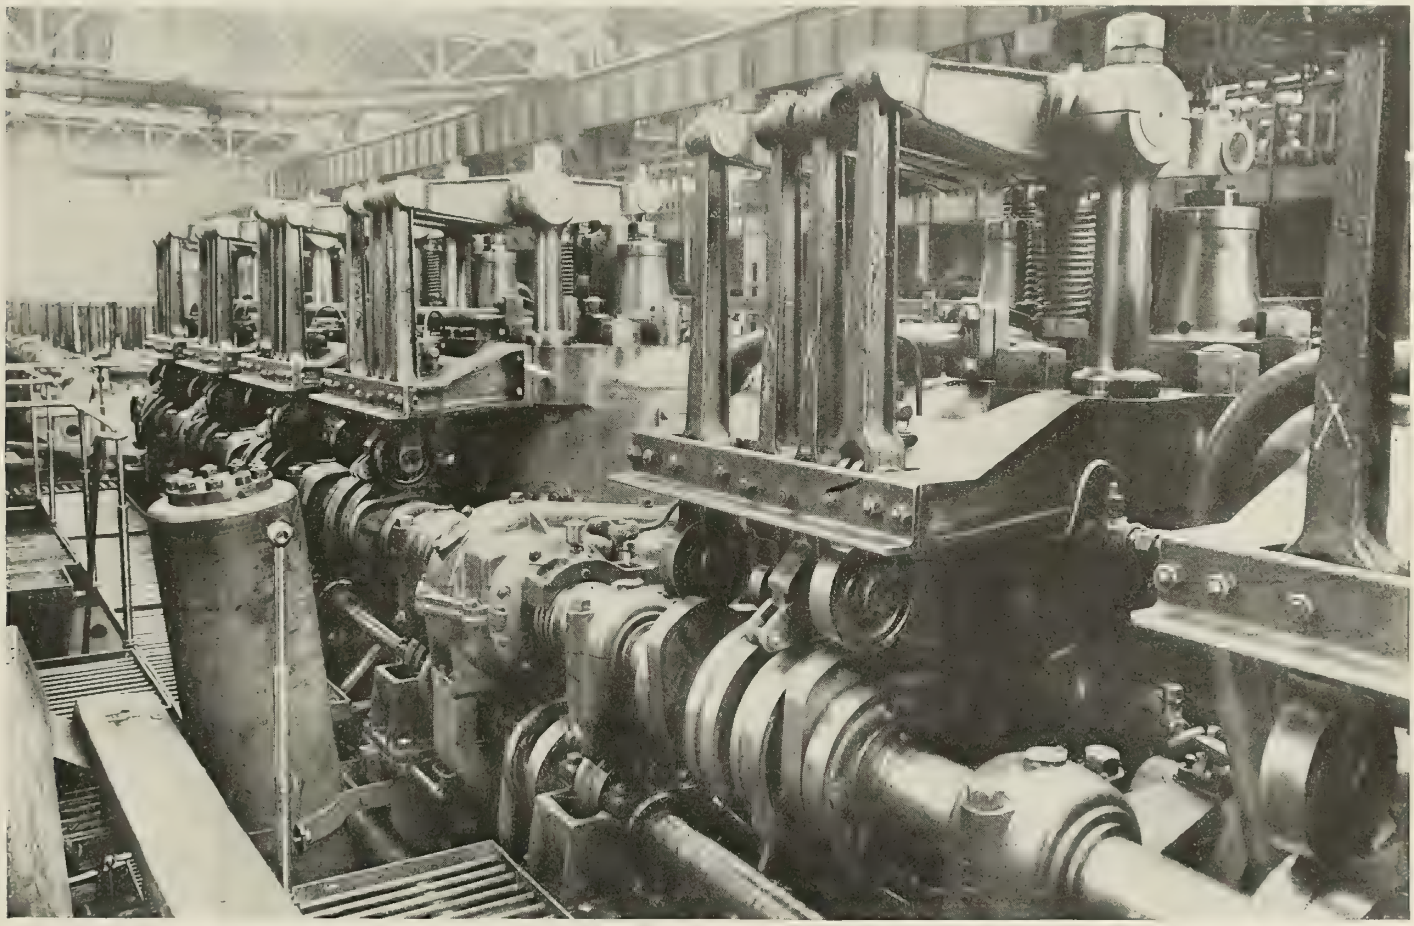
Galley Features

The galley is situated on the main deck aft of the engine casing. An interesting feature is that there is a passageway from the galley to the dining saloon inside the main passageway so that the movement of the passengers is not impeded by the dining saloon attendants. This again means a certain loss of space but it has obvious advantages. The dining saloons and other public rooms are heated by electric radiators but the galley is coal fired, while hot water for the boiling vessels, etc., is supplied from a donkey boiler in the engine room.

Above the main deck is the bridge deck with further passenger accommodation, many of the cabins at the forward end being provided with a single bed. Above this is the promenade deck, with the first class entrance dividing the music saloon from the smoking room, while at the after end of the same deck is the second class smoking room and the music room. The boat deck, as previously mentioned, has accommodation for the officers and engineers. Above the navigating bridge are the captain's dayroom and bedroom. All of the cabins are provided with running water with overboard discharge, a convenience realized only by the experienced traveller. An electric fan is fitted in each room, large ceiling fans being provided in the public rooms.

Machinery Installation

The machinery installation represents the first of its class that has yet been installed in any vessel and is a twin screw plant developing a total of 4,000 brake horsepower, which on trials gave the vessel a speed of 13¾ knots. It was built by the North British Diesel Engine Works in Glasgow and each engine has eight cylinders, 26½ inches diameter and 47 inches stroke. When running at 96 revolutions per minute the full power (which is equivalent to about 2,350 indicated horsepower) is developed, but it is to be noted that although the engines are of the usual air injection type, they do not drive their own air blast compressors.



Top of One of the 2,000 Brake Horsepower Engines of the Domala, Showing Valve Operating and Reversing Mechanism

New Design Features

Each engine is some 44 feet in length overall and arranged in two groups of four cylinders, with the reversing mechanism in the center. Apart from the Burmeister and Wain and Worthington types, no four cycle Diesel marine motors of larger size have yet been constructed and in the design one or two novel features have been introduced. On the top of the cast iron frames, which do not take the cylinder stresses, is carried an entablature which supports the cylinders. Long vertical steel columns pass from the bedplate to the top of this entablature and relieve the framing of the stresses, the construction in this respect being somewhat similar to that employed with the newest Burmeister and Wain engine.

A marked difference is, however, to be noted in the valve

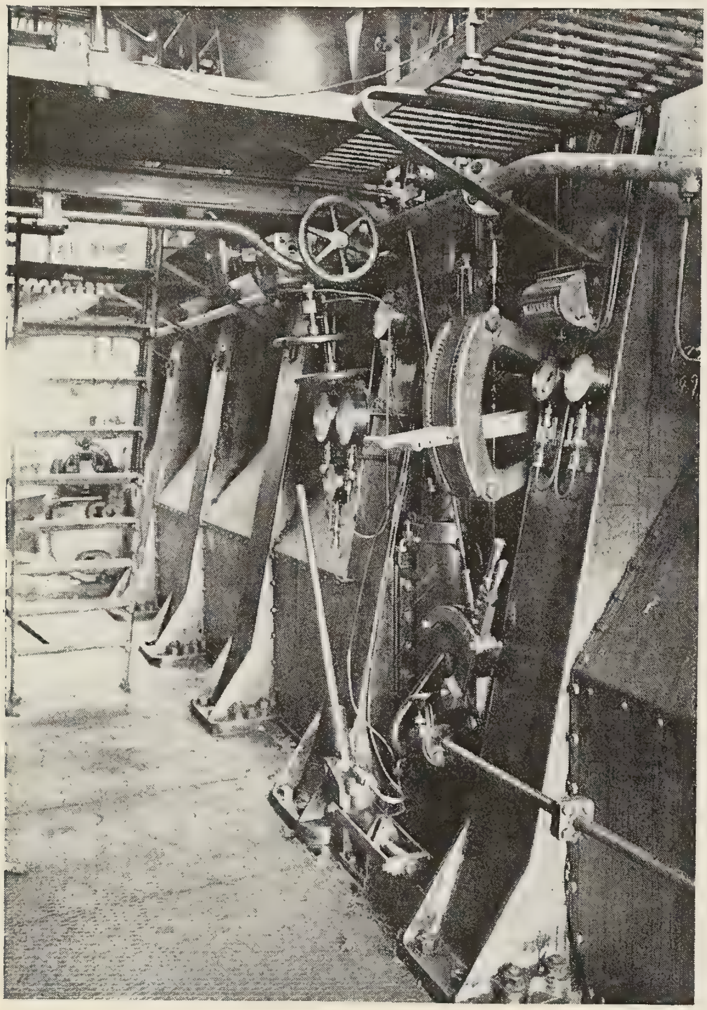
PLAN AT MAIN DECK

Machinery Arrangement of Motorship Domala

operating and reversing mechanism, which is quite novel. There are eight cams on the camshaft for actuating the four valves in each cylinder, one set for ahead and the other for astern running. The movement of the valves is effected through push rods and horizontal rocking levers. When it is required to bring the astern cams into action, the servo motor controlled from the starting platform causes the camshaft to be lowered and then moved in a longitudinal direction so as to bring the astern cams into position. The camshaft is then raised and the mechanism is correctly timed for running astern.

The heavy bedplate of the engine is of box section and is in four parts. The comparatively light frames mentioned



Control Station of One of the 2,000 Brake Horsepower Engines on the Domala

above carry the crosshead guides. The piston cooling water reaches the piston head through a hole in the piston rod. Sea water is used for piston and for cylinder cooling but separately driven electric pumps are provided in the engine room for this purpose, the pressure of the piston cooling water being somewhat above that of the circulating water used for the cylinders and cylinder covers. The eight fuel pumps are driven from a spur wheel on the vertical shaft, transmitting the crankshaft motion to the camshaft and the speed of the engine is controlled in the normal manner by the two throttle levers (one for each group of four cylinders) varying the period of opening of the suction valves of the fuel pumps.

Auxiliary Machinery

The auxiliary machinery calls for some comment as part of the system has not previously been adopted on any motor ship. There are two large three stage air compressors each coupled to a six cylinder Diesel engine of 400 brake horsepower which serves for the supply of blast injection air as well as that required for starting purposes. This is necessitated in view of the fact that the main engines do not drive their own compressors. When the vessel is at sea one of the Diesel driven compressor sets serves for both main propelling motors, although it will apparently be nearly loaded up to full power, thus indicating the amount of power taken by the blast air compressor on a Diesel engine.

The electrical generating plant comprises a couple of 300 horsepower six cylinder Diesel engines running at the extremely high speed of 375 revolutions per minute and driving 220-volt 215-kilowatt direct current generators. All the engine room pumps including two cylinder cooling, one piston cooling, two lubricating oil, ballast, fresh water, sanitary and bilge pumps are coupled to electric motors, but the boiler will have to be in service the whole time at sea owing to the galley requirements.

An electric refrigerating plant is provided and there is an emergency dynamo driven by a hot bulb engine to supply electric power in case of the engine room being flooded.

Navy Yards Cannot Bid for Reconditioning of Leviathan

PRESIDENT HARDING has announced in a letter to Representative Dallinger of Massachusetts that the work of reconditioning the *Leviathan* cannot be done at the Boston Navy Yard, as urged by Mr. Dallinger, but that the contract will be let, if Congress is willing to appropriate the necessary funds, to the private company that makes the lowest bid. The President gave as his reason that a navy yard cannot, under the laws, submit a definite bid for the work and also that it is the policy of the administration, as well as of the Jones merchant marine law, to encourage private shipbuilding enterprises. He also pointed out that insofar as the work would tend to relieve unemployment, the result would be the same wherever the work is done.

While no direct appropriation for the *Leviathan* has been asked by the Shipping Board, the question as to whether the money should be spent has been put up to Congress in the statements made before the appropriations committee by officials of the board, who have shown how much money is needed for various purposes and just what use it is proposed to make of it. An estimate of the amount necessary to recondition the ship has been included in the calculations as to the use proposed to be made of the appropriation of $55,000,000 from the proceeds, if the liquidation of assets is continued.

Conference of Maritime Nations Proposed

HOMER FERGUSON, president of the Newport News Shipbuilding and Dry Dock Company, in a conference with the President on January 9, attended also by Chairman Lasker of the Shipping Board and Senator Jones, urged that a plan be submitted to the arms limitation conference for calling a conference of the leading maritime powers to discuss merchant marine questions, including a proposal for a pooling of ocean commerce so that the ships of each nation could be assured of 50 percent of the direct traffic to and from its ports. The President was not in agreement with this suggestion, on the ground that the agenda of the arms conference should not be added to, but expressed the opinion that there are many questions which might profitably be discussed at such a conference at some other time.

Diesel Electric Propulsion of Ships

Advantages of Diesel Electric Drive—Types of Vessels for Which It Is Applicable—Comparison With Steam

By Commander S. M. Robinson, U. S. N.

At the present time the greatest interest is being manifested by all marine engineers in the development of the Diesel engine for marine purposes. This is doubtless partly due to the fact that the World War practically stopped all development of the marine Diesel engine except in the case of the submarine as there was no time for experimental work. But this check seems to have given added impetus to the development work going on at the present time. This is particularly true of the European shipbuilders. The British have tackled this problem with characteristic thoroughness as is evidenced by the great number of types of marine Diesel engines that they have under construction and in operation.

The saving in fuel that is effected by the Diesel engine over all other forms of propulsion is so great that it appears to be only a question of a short time before it will entirely replace steam in certain classes of ships and eventually it will probably be found in all classes of ships. The increasing cost of fuel makes this saving of greater importance as time goes on. This fact is apparently recognized in Europe where a large percentage of ships building are being equipped with Diesel engines.

It would seem that the development of the Diesel engine could be carried on much more rapidly, if every one appreciated the possibilities of electric drive in connection with it.

Advantages of Diesel Electric Drive

For one thing, it makes possible the use of large powers at once; it is not necessary to wait till the Diesel has been developed in large units as a number of small units can be used to give the desired power.

Also, the Diesel is inherently poor in maneuvering qualities; for example, its speed cannot reliably be reduced below about one-third speed and it has to be started and reversed by air. The use of air is not only entirely unsatisfactory but is distinctly bad for the engine; also air control requires complicated valve mechanism (and therefore complicated cylinder heads) and air storage bottles. These disadvantages are entirely done away with by the use of Diesel electric propulsion.

The present practice in regard to the speed of the Diesel engine gives a propeller that is not the most efficient and the tendency is toward still higher speeds. One need only compare the high speed engines of a submarine with those of a merchant ship to see what the possibilities are in regard to saving weight by increasing the speed. With electric propulsion, the higher the speed of the engine the more suitable it will be as a prime mover and the motor speed can be arranged to give the most efficient screw.

There is no question but what very little time and money have been spent on the development of a reliable high speed engine as compared with what has been spent on the slow speed engine. When more attention is paid to obtaining perfect balance, it is probable that the high speed engine will develop very rapidly as it will make it possible to get large powers with small cylinders, thus avoiding many of the difficulties of design.

The reliability of the Diesel engine is much improved by the use of electricity in connection with it; this is due partly to the fact that air starting and reversing are eliminated and partly to the use of multiple units; this latter advantage will be discussed more in detail when considering individual cases.

These are the general advantages of Diesel electric propulsion but a proper discussion of this subject can be had only by considering each type of ship separately and in each case the conditions must be chosen to represent actual conditions as nearly as possible. Several papers have recently been presented on this subject and they have not followed this rule; for example, if we have a 2,000 shaft horsepower ship driven by twin Diesel engines running at 150 revolutions per minute, obviously it is no comparison at all if we choose twin screws running at the same speed for the electrically propelled vessel. To get a real comparison, we should use a single screw running at about 90 revolutions per minute, otherwise we deliberately throw away a very considerable part of the advantage of the electric propulsion for this case.

Why Direct Current Is Used

The first question to be decided in connection with Diesel electric propulsion is whether direct current or alternating current will be employed. Where it is desired to have two or more units operating together to drive the motor (or motors) on one propeller shaft, it will be advisable to use direct current. This is due to the fact that Diesel engines do not operate well in parallel as the governor regulation is not sufficiently good. It is true that Diesel driven generators are successfully operated in parallel on shore but it would be out of the question on board ship or any place where it is necessary to change the speed of the engines while keeping them in parallel as would be the case if alternating current were used. By using direct current, the generators and motors can be operated in series so that close regulation of the engine speed will not be required. Direct current also obviates the necessity for changing the engine speed since speed variations can be taken care of by varying the generator or motor voltage.

When using direct current, series operation will usually be desirable not only because it is more suitable for the engines but also because it is better electrically. Voltage variation would be used for propeller speed control and, with parallel operation, this would require generators with practically identical saturation curves and very carefully adjusted field rheostats, while with series operation no such requirements would exist. But more important still, the failure of one unit reduces the power more with the parallel than with the series operation since in the former case it would be necessary to reduce the generator voltage to accomplish the necessary reduction in propeller speed and this would lower the output of the generators. With series operation, the generators would work under practically full load conditions regardless of the number in use.

When Alternating Current Would Be Advisable

In the case of ships fitted with two or more propellers, each having its motors driven by its own generator, it will usually be preferable to use alternating current owing to the greater efficiency of transmission. In the case of large powers, there would also be greater reliability and a reduction in weight and space. Here the difficulties previously mentioned would not exist since the generators would not be operated in parallel and the speed of each engine would be independently controlled. In case of failure of one generating unit, the other would be used to drive all motors, the latter being operated in parallel, which would be satisfactory.

The first type of vessel to be considered will be the low powered merchant vessel since Diesel electric propulsion offers more advantages for this type of vessel than for any other at the present time.

Application to Low Powered Merchant Vessel

The power involved is small so that the generators used for propulsion will also be suitable for furnishing power to run the deck winches when in port. This represents a large saving in weight and space and gives economical service.

There will be no loss of propulsive efficiency due to the use of the electric transmission with these ships. This is due to the fact that a single, large, low speed propeller will be used with the electric propulsion and two propellers of higher speed with the direct propulsion. The appendage resistance with the two-propeller arrangement added to the increased thrust deduction just about makes up for the electric losses. The single, low speed propeller is more efficient than the high speed propellers so that the overall efficiency should be somewhat greater with the electric propulsion than with the direct propulsion.

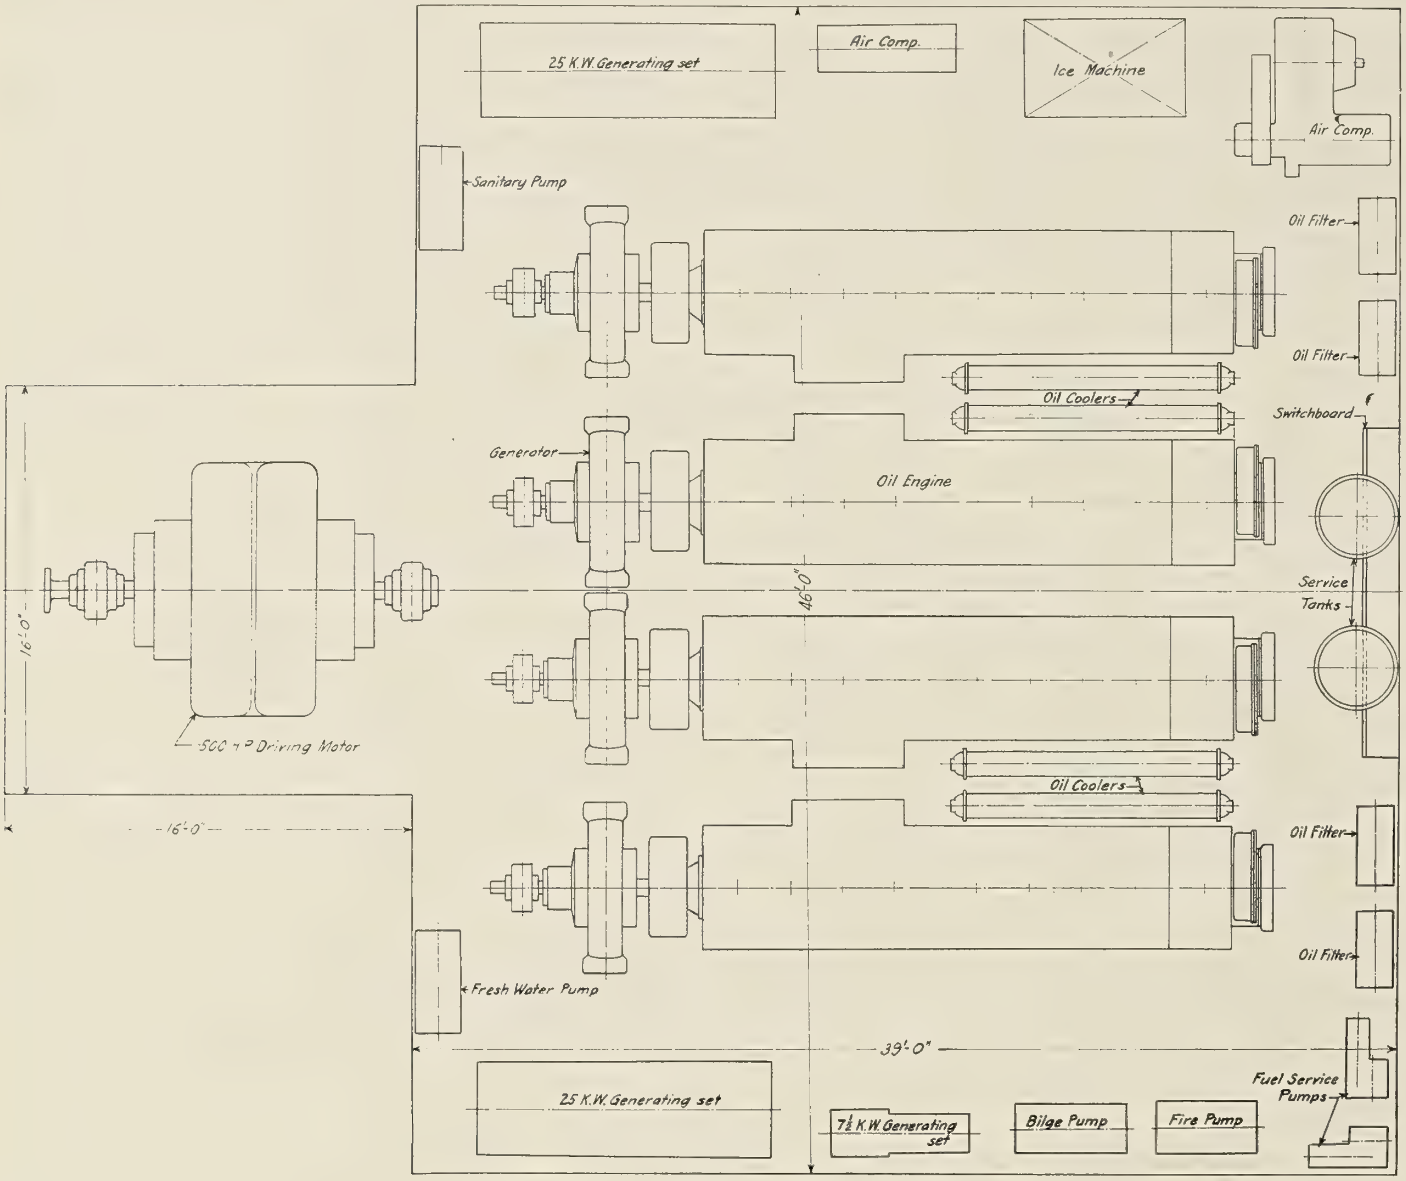


Fig. 1

Arrangement of Machinery

An ideal arrangement for this type of ship consists of three generators driving two motors on one propeller shaft. The generators and motors would be separately excited. The excitation would be furnished either from small generators direct connected to the main units or from separate generators which could be used for furnishing power to the ship's circuits. When using the main units, the direct-connected exciters not used for excitation would be used for the ship's circuits, thus making it possible to shut down all generators except the main units.

All units would be started electrically, using the generator as a motor. Power for this purpose would be furnished by small independent generators; these, in turn, would be started by a small generator which could be started by hand so that it would never be necessary to use air for starting.

The generators and motors would all be connected in series; reversal would be accomplished by reversing the generator field. With this type of ship, it would not be necessary to provide armature resistance to get the necessary torque for reversal; the friction load of the Diesel engine, shafting, etc., is sufficient for this purpose in this case. With high speed, high powered ships this would probably not be true.

Speed Control

Speed control would be accomplished by varying the field of the generators or the motors or changing the speed of the engines, according to circumstances. Normally, speed changes

would be effected simply by varying the generator field strength and this method would always be used for maneuvering.

To show how the different methods of speed control can be used and also how the ship would be operated at reduced power, the case already assumed—that of three generators and two motors—will be analyzed in detail.

If it were desired to operate at full speed all units would be in use. Reduction of speed would be accomplished by decreasing the generator field strength. If it were intended to make a trip at slightly less than full speed, it would probably be best to operate the engines at a slightly reduced speed. This speed once set, however, would not be changed.

If one main unit were out of commission, the other two generators and the motors would be run in series. The generators would be run at normal speed and would carry the same current and voltage as before and would therefore have the same efficiency as before. There would be available two-thirds (67 percent) of the full power and since the power varies approximately as the cube of the revolutions, the propeller would run at 87 percent of its full speed and the ship would be propelled at 87 percent of its full speed. Since the torque varies as the square of the revolutions, the torque required would be 77 percent of the full load torque and therefore the field strength of the motors would be 77 percent of full field; each motor would be developing 67 percent of its normal full power and would fall off slightly in efficiency. To sum up this condition, the generators would be operating at 100 percent speed, 100 percent voltage, 100 percent current and normal efficiency; the motors would be operating at 67 percent power, 87 percent speed, 77 percent field strength, 100 percent current and slightly reduced efficiency; the ship would be propelled at 87 percent speed. Speed reduction would be accomplished by decreasing the field strength of the motor.

If two main units were out of commission, the remaining unit and one motor would be used. The generator would be run at normal speed, current and voltage and therefore the efficiency would be the same as at full power. The propeller would run at 70 percent speed. The torque on the propeller shaft would be 50 percent of that at full power but since only one motor would be used that motor would develop 100 percent of its full load torque and would therefore carry 100 percent normal field strength since it would be carrying normal full load current. There would be a slight decrease in motor efficiency. To sum up this condition, the generator would be operating at 100 percent speed, 100 percent voltage, 100 percent current and normal efficiency; the motor would be operating at 67 percent power, 70 percent speed, 100 percent field strength, 100 percent current and slightly reduced efficiency; the ship would be propelled at 70 percent speed. Speed reduction would be accomplished by decreasing the generator field strength.

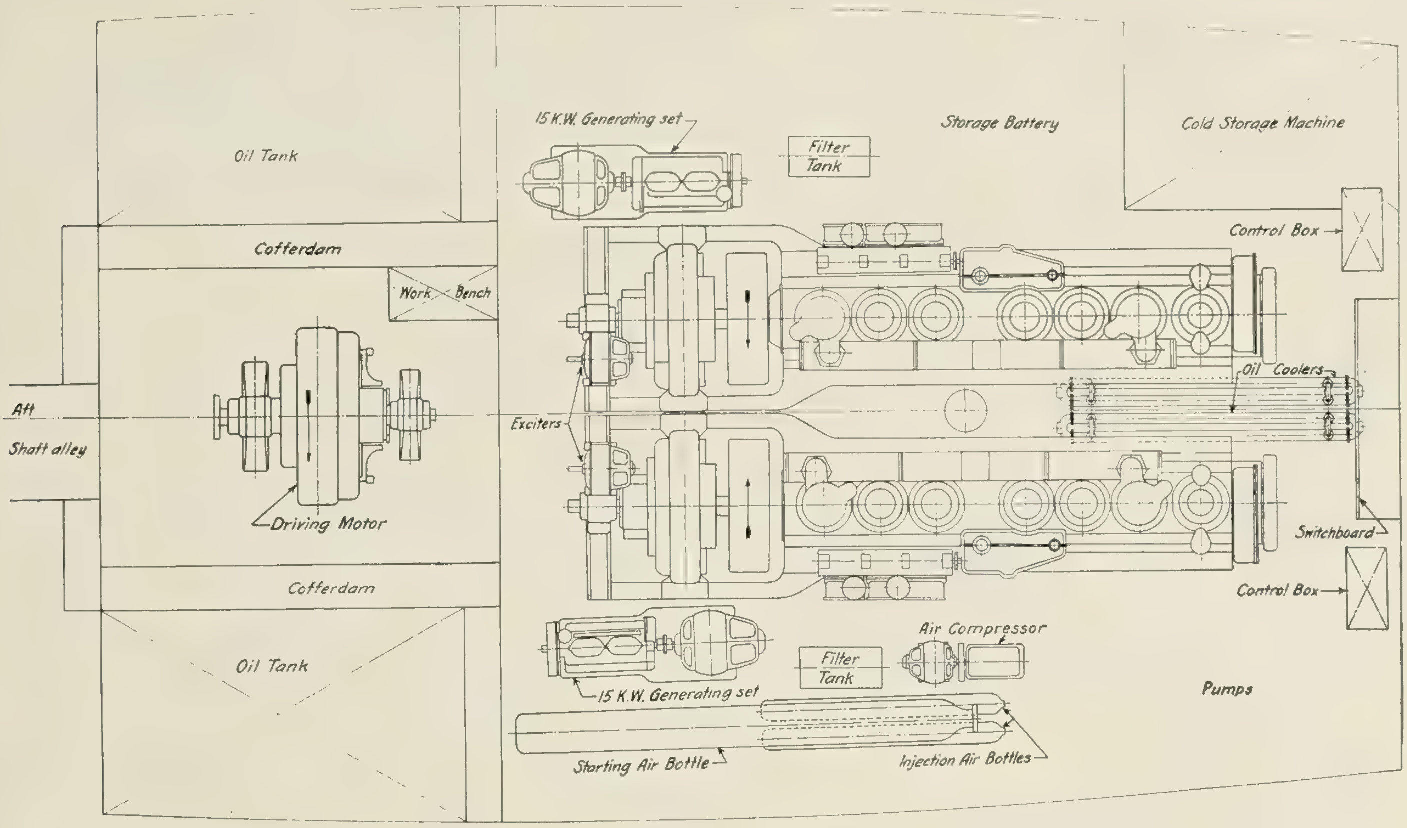

Fig. 2

Proposed Merchant Ship Installation

An arrangement for Diesel electric propulsion as proposed by the Winton Company is shown in Fig. 1. This arrangement consists of four main units and two main motors arranged as a double armature motor to save space and weight. There are two 25-kilowatt generating sets for general ship's service and a 7½-kilowatt generator arranged for hand starting. All auxiliaries are motor driven. The main units are provided with direct-connected exciters which can be used either for excitation or ship's service. The voltage of the main generators is such that they can be used for running cargo winches.

Diesel electric propulsion offers a means of modernizing ships which are equipped with steam plants. For example, many of the Emergency Fleet Corporation ships which are equipped with turbines and reduction gears could readily be converted into Diesel electrically propelled ships without any change in propellers, shafting or bulkheads. This would make these ships operate at about one-third of the present fuel consumption.

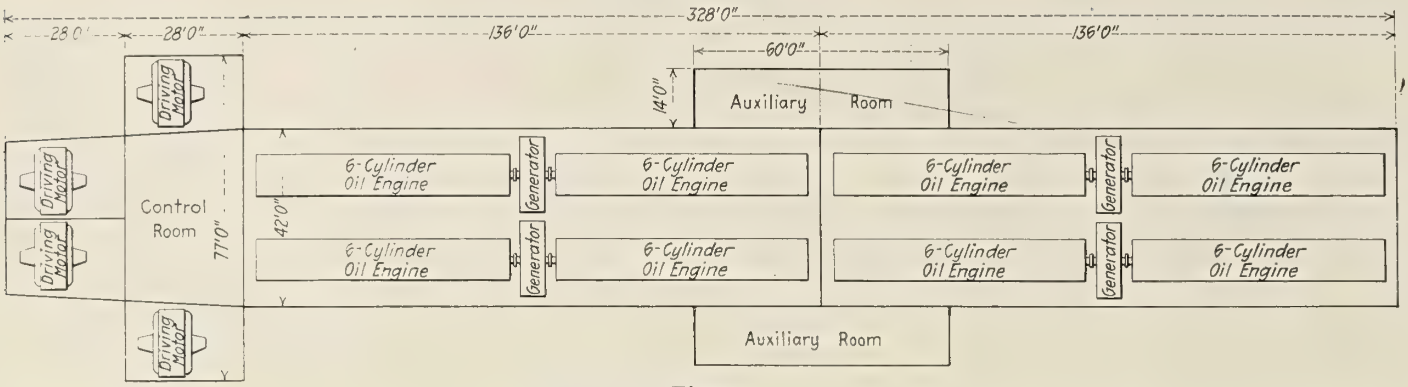

Fig. 3

Yachts and Pleasure Craft

The next class of vessel to be considered will be yachts and other pleasure craft. The special advantages of Diesel electric propulsion here are that it provides a long cruising radius at reduced power and at the same time gives high speed for short runs; also the machinery can be located so as to give the best accommodations for the passengers. The advantage in regard to increased cruising radius is quite marked. Assume that cruising would be done at about half power; the direct connected Diesel would be run at about 79 percent speed and 50 percent power, if both engines were used or else at not more than about 70 percent speed and 70 percent power (assuming that the normal mean effective pressure should not be exceeded), if one engine were disconnected and the screw allowed to revolve freely while the other engine was used for driving the ship. The latter arrangement would necessitate the use of clutches for disconnecting the engines. In the first case the engine efficiency would not be nearly so high as at full power; in the second case, the horsepower required would be very materially increased by the dragging screw; in neither case would the propeller efficiency be as high as for the single screw electric arrangement. With the latter, the ship would cruise at 79 percent speed with one main engine running at full speed and full power (assuming two units to be installed).

An arrangement of machinery for Diesel electric propulsion for this type of vessel is shown in Fig. 2, which is a plan of the engine room of the schooner yacht *Guinevere.* The machinery consists of two 350-horsepower Winton engines operating at 225 revolutions per minute and driving two 225-kilowatt Westinghouse generators, and a 550 horsepower Westinghouse motor driving a propeller at 220 revolutions per minute. A 15-kilowatt exciter is connected to each main unit by a chain drive. All of the generators give 125 volts. All auxiliaries, including the steering engine, are electrically driven.

Double Ended Ferryboat

Another type of vessel for which Diesel electric propulsion offers special advantages is the double ended ferryboat. As usually arranged, these boats have two propellers, one at each end of the ship; both are placed on the same shaft and are driven by an engine located near the center of the ship.

This is an extremely inefficient arrangement since both screws are driven at the same speed. The result is that the screw current of the forward screw is discharged against the bow of the boat and adds enormously to the horsepower required to drive the boat through the water. This may amount to 40 percent or more of the effective horsepower required to propel the ship.

The proper method of operating these propellers is to drive the forward propeller at a speed just slightly above that at which it would run if it were allowed to revolve freely while the ship is being driven by the other propeller—in other words, just fast enough to prevent it from acting as a drag on the ship. This speed is approximately 70 percent of the revolutions corresponding to the speed of the ship. This method of operation requires that the two propellers be on separate shafts. With electric motors, it is a very simple matter to adjust the speeds of the two motors quite accurately and quickly since it would be a matter only of watching the ammeters of the two motors. The same result might be approximated in an engine-driven boat by using a separate engine to drive each propeller but there would be no means of adjusting the speeds accurately and, in any case, the method would not be efficient since one engine would always be running with practically no load.

Flexibility of Installation

Another advantage of this method of propulsion for this type of vessel is the flexibility in regard to installation. This is well illustrated by the ferryboat *Poughkeepsie* being built for the Highland Ferry Company. This vessel has a very wide flat hull with a "hull-fin" extending below the main hull. The hull-fin carries the propelling motors and in this case is nothing but a deep shaft tunnel. It would hardly be possible to place engines in such a narrow compartment but it enables the propellers to work in solid water as they are entirely housed by the hull and also to work in water which is unbroken since there are practically no obstructions ahead of the propellers.

The stability of the vessel is obtained by the use of the broad flat hull which makes it practically impossible to capsize her by loading. Unfortunately, the *Poughkeepsie* is arranged with both motors and both propellers on one shaft so that the great advantage of increased propulsive efficiency will not be realized.

Reliability in Maneuvering

For ferryboats perhaps the most important advantage of the Diesel electric over the direct Diesel drive is the greatly increased reliability in maneuvering. It is perhaps no exaggeration of the facts to say that, at the present stage of development, electricity makes possible the use of the Diesel engine with this type of vessel.

Other more minor advantages of Diesel electric as compared with steam installations are the absence of stand-by losses when the vessel is not running and the absence of a smoke pipe which makes it possible to have a perfectly clear main deck, thus much improving the freight and passenger carrying space.

The limitations as to size have in the past prevented the consideration of the Diesel engine for high powered ships such as capital ships of the Navy and passenger vessels but the present rapid development of this engine indicates that these limitations will shortly be removed. Even at the present time, several of the best engine builders are prepared to furnish units of 6,000 brake horsepower in six cylinders. It is interesting to see what could be done with an installation in a capital ship using this unit as a basis.

DIESEL ELECTRIC DRIVE FOR A CAPITAL SHIP

Fig. 3 shows an outline of such an installation. It consists of eight 6,000 horsepower engines driving four generators which furnish current to four induction motors driving four propellers. The 12,000 horsepower generator is placed between the two engines so that it is unnecessary to transmit power through more than six cranks. The installation will also be lighter and occupy less space than it would if a separate generator were used for each engine. There is, however, a more important reason for not using more than four generators.

For transmitting this amount of power it will be preferable to use alternating current at much higher voltage than would be possible with direct current. This is desirable from the standpoint of efficiency, weight, space and reliability. The objections to the use of alternating current disappear with this type of installation since each generator would drive its own motor and the generators would at no time be connected together. When cruising at reduced speeds either one or two generators would be used. In the first case the motors would all be in parallel; in the second case, each generator would drive two motors connected in parallel, on one side of the ship.

COMPARISON OF WEIGHTS

It is interesting to compare the weight of such an installation with a steam drive. It is estimated that the main units of the installation described above would weigh about 3,120 tons; this includes the weight of the Diesel generators, main motors, switchboards and cable. The total installation in the ship would weigh about 4,130 tons. A corresponding steam installation would weigh about 3,560 tons or 570 tons less than the Diesel electric. If we assume a fuel supply of 3,000 tons for the steam installation, this would leave 2,430 tons for the Diesel electric in order that the two should have equal weight at the beginning of a cruise. The Diesel electric installation would use not more than half the fuel that the steam drive would require so that the cruising radius would be increased $\frac{2430}{1500}$ or 1.625 by the use of Diesel electric propulsion.

There is no question but what the future development of the Diesel will give us a lighter engine for the large powers so that the comparison in regard to fuel will be even greater in favor of the Diesel. The double acting Diesel is still in its infancy and the same can almost be said of the crosshead engine; but that the development of the Diesel from now on will be rapid no one can doubt and it would appear that, eventually, there should be no limitation as to its uses for marine purposes.

Diesel Electric Cargo Vessel Fordonian Given Trial

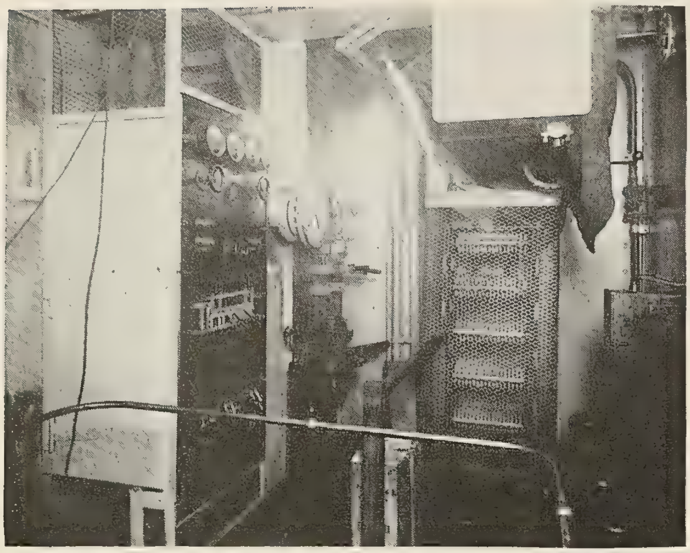
First American Sea-Going Motorship to Be Fitted With Diesel Electric Method of Propulsion

THE *Fordonian,* the first ocean going merchant ship in the United States to be equipped with the Diesel-electric method of propulsion, was given her official sea trial on January 13. A party of over fifty prominent marine engineers and shipping men attended the trial, which shows an unusual amount of interest in the claims set forth for the adoption, from the economical standpoint, of the Diesel electric drive for cargo ships.

The *Fordonian,* which was formerly fitted with direct Diesel drive, was re-engined by the Tebo Yacht Basin of the Todd Shipyards Corporation. She is 250 feet long with a 42-foot beam and has a gross tonnage of 2,368 tons. The vessel is owned by the American-Mediterranean Steamship Company, McDonnell and Truda, agents, and will be engaged in the freight traffic between New York and Havana. The *Mariner,* a 200-ton fishing trawler, is the only other commercial ship with a similar machinery installation in this country today.

The *Fordonian* represents the culmination of several years of development work in successfully adapting electric trans-

Motorship Fordonian, Equipped with Diesel Electric Drive, on Her Trial Trip



View of Switchboard, Rheostat and Operating Station

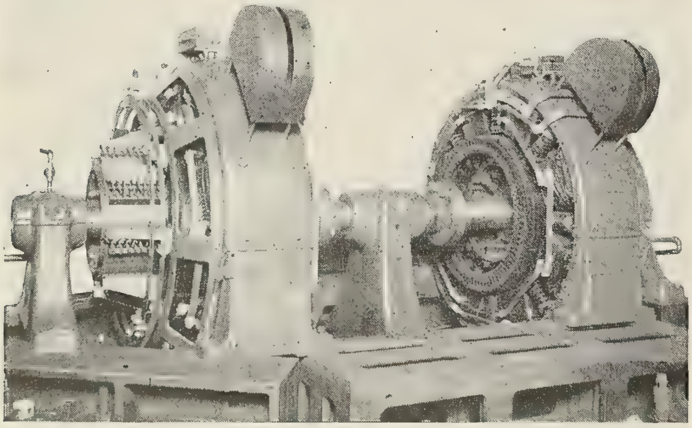
Propelling Motor and One of the Main Engines

mission to the oil engine for large ships. The electric apparatus is of the General Electric Company type consisting of two 350 kilowatt generators each driven by a two cycle four cylinder Ansaldo San Giorgio Diesel engine of 500 brake horsepower. Motive power is supplied by a double armature 850 horsepower motor direct connected to the propeller and designed to furnish a speed of about nine to ten knots.

The control is from the engine room and has been devised to give the utmost flexibility of operation. The main control equipment consists of a panel on which are mounted the various switches, field rheostats and instruments; a master controller for operating the contactors of the control group; the control group for starting and reversing the motor, and a starting resistor and motor field resistor for obtaining lower speed ranges. The normal operating propeller speed is 120 revolutions per minute. The control arrangement allows for the use of either or both generators supplying current to the propeller motor, depending upon the speed requirements.

Captain C. J. Dyer of the *Fordonian* declared after the trials that the performance of the ship had exceeded his best expectations and that the ease with which she was maneuvered and controlled in the congested shipping of New York Bay "gives promise of a bright future for ships using Diesel engines in combination with electric drive. I wouldn't change her for a steam driven ship under any condition." W. N. Hooks, chief engineer, was equally pleased with the performance of the ship.

The *Fordonian* developed a speed of 10.12 knots on the trial, which greatly exceeded the expectation of the captain. In order to develop full propeller speed of 120 revolutions per minute the motor developed 720 horsepower at the propeller shaft. With the ship fully loaded the motor will be called upon to deliver the full rated horsepower of 850 in order to turn the propeller at this speed.



Two 350-Kilowatt Direct Current Generators for the Fordonian

Prominent Shipping Men Attend Trial

Among the engineers present at the *Fordonian's* trials were the following: P. Bryan, General Electric Company; J. J. Brown, Westinghouse Electric Company; A. F. E. Horn, General Electric Company, Washington, D. C.; G. Smith, United States Engineers Office, War Department, Washington, D. C.; T. R. Vogel, United States Engineers Office, War Department, Washington, D. C.; Lieut. Col. H. Allen, United States Engineers Office, War Department, Washington, D. C.; Commander S. M. Robinson, U. S. N., Bureau of Engineering, Navy Department, Washington, D. C.; Commander Jones, U. S. N., Washington, D. C.; Commander Walton, United States Coast Guard; W. P. Marshouse, Pennsylvania Railroad Company; E. Keane, United States Government; P. J. O'Reilly, United States Boiler Inspector; H. Ehrlich, Custom Inspector; H. Westlake, Custom Inspector; W. Richardson, Custom Inspector; R. O. Dunham, T. S. Gandy and B. S. Beach, General Electric Company, Schenectady, N. Y.; L. R. Ford, Worthington Pump and Machinery Corporation, New York; L. V. Armstrong, Ingersoll-Rand Company; H. Schreck, Consulting Engineer, New York; S. Wright, Busch-Sulzer Bros.-Diesel Engine Company, New York; F. J. Moran, General Electric Company, Philadelphia, Pa.; M. J. Hekking, Texas Oil Company, New York; Theodore D. Wells, Naval Architect, New York; T. O. Lisle, Editor *The Motorship;* C. H. Kennerly, Old Dominion Transportation Company; H. Lund, Chief Engineer; A. St. James, Texas Oil Company, New York; N. R. Sibley, Westinghouse Electric Company, New York; George L. Kay, Surveyor, American Bureau of Shipping; George Pogue, Busch-Sulzer Bros.-Diesel Engine Company; F. B. Webster, Editor Marine Engineering and Shipping Age; W. M. Johnston, John Bliss and Company; J. B. Bassett, General Electric Company; M. S. Katzenstein, Worthington Pump and Machinery Corporation; L. G. Nunes, and G. Campiglie, Ansaldo Engine Company; J. W. Anderson and G. E. Edgar, New London Ship and Engine Company; P. Levinthol, Naval Architect, New York; A. Kennedy, W. H. Wild and J. Thomas, General Electric Company, N. Y.; P. McDonald, McDonald and Truda; Paul Henning and H. B. Taylor, United States Shipping Board.

Motor Tanker Zoppot, Fully Laden

The Motor Tank Ship Zoppot*

The successful operation of the Zoppot over a period of eighteen months has brought the Diesel engine into prominence as satisfactorily meeting the service requirements for propelling machinery in large tankers. Heretofore the reciprocating steam engine has found the greater favor for this type of vessel on account of the quick turn around in port and the ability of the steam engine to stand up under continued service. The performance records of the Zoppot prove the ability of the Diesel engine to meet demands for reliability and undoubtedly will lead to keener interest in this more economical type of machinery when solving the powering problems of future tankers.

THE motor tank ship *Zoppot*, which has been in service for over a year, covering 44,000 sea miles in the first ten months, has attracted considerable attention as a tanker, as well as a motorship, owing to its great size and carrying capacity. The *Zoppot* was built in the shipyard of Fried. Krupp Aktien-Gesellschaft of Kiel-Gaarden, Germany, for the Baltic American Petroleum Import Company of Danzig. It was recently taken over by the Standard Oil Company of New Jersey, however, and is now operating in the service of that company between New York, Baltimore and Mexico. Its style of construction and the installation of its main and auxiliary engines offer many notable improvements.

The vessel was constructed in conformity with the highest class of British Lloyd's with the designation ✠ 100 A-1 under special supervision and in accordance with the longitudinal system of framing. The *Zoppot* is the first large motor tank vessel built according to this system and the expectations of the builders have been entirely realized, for not only has more than 8 percent of the steel weight been saved as compared with transverse frame construction, which saving has added to the profits through increased cargo carrying capacity, but the longitudinal and transverse strength have in every instance been excellent. This was confirmed by experience on the first trips when, despite continuously heavy seas, no weak spots appeared in the strengthening of the hull. It must, however, be noted that the builders exceeded the requirements of the British Lloyd's and increased the scantlings of the reinforcement wherever they appeared insufficient, experiences gained with smaller vessels built according to the longitudinal framing system indicating the correctness of this precaution.

The principal dimensions and main particulars of the *Zoppot* are given in the following table:

Length overall	546 feet 11 9/16 inches
Length between perpendiculars	524 feet 11 inches
Breadth, molded	66 feet 2½ inches
Depth, molded to upper deck	41 feet 2 7/16 inches
Draft with summer freeboard	27 feet 7¼ inches
Deadweight at this draft	15,500 tons
Gross tonnage	9,932
Net tonnage	5.915
Horsepower, shaft	3,600
Speed, knots	10.5

The ship is built as a shelter deck vessel and has three continuous decks. The hold, which extends from the keel to the main deck, is divided by transverse bulkheads and a centerline longitudinal bulkhead to provide 22 cargo oil tanks, 11 on each side of the vessel. Cofferdams are fitted at the forward and after ends of the cargo tanks. A cofferdam is also arranged between tanks 2 and 3 and this, with the pump room, located amidships, separates the cargo tanks from each other in such a manner that three different kinds of oil can be carried simultaneously. On the second deck, outboard of the expansion tanks, are the summer tanks, of which there are also 22.

The total capacity of the cargo holds for oil amounts to 693,246 cubic feet. In addition to the tanks for liquid cargo there is a cargo hold between the collision bulkhead and the forward cofferdam and the entire space between the main deck and the shelter deck is also available for cargo. The capacity of these spaces amounts to 229,446 cubic feet.

The engine room, as customary in large tank vessels, is located aft.

Hull

The construction of the hull is similar to the usual practice for longitudinally framed vessels.

There are 22 longitudinal frames on each side of the vessel below the main deck and 2 longitudinal frames between each of the decks above. Web frames are spaced 9 feet 2¼ inches apart and, as the cargo holds are uniformly 27 feet 6¾ inches long, there are 2 cross frames for each cargo hold. The oil tight longitudinal and transverse bulk-

*Translated from an article by Managing Director Oesten, Chief Engineer Alt., and Engineer K. Von Sanden of the Fried. Krupp Aktien-Gesellschaft, Germaniawerft, Kiel-Gaarden, Germany, which was published in *Werft und Reederei*, July 7, 1921.

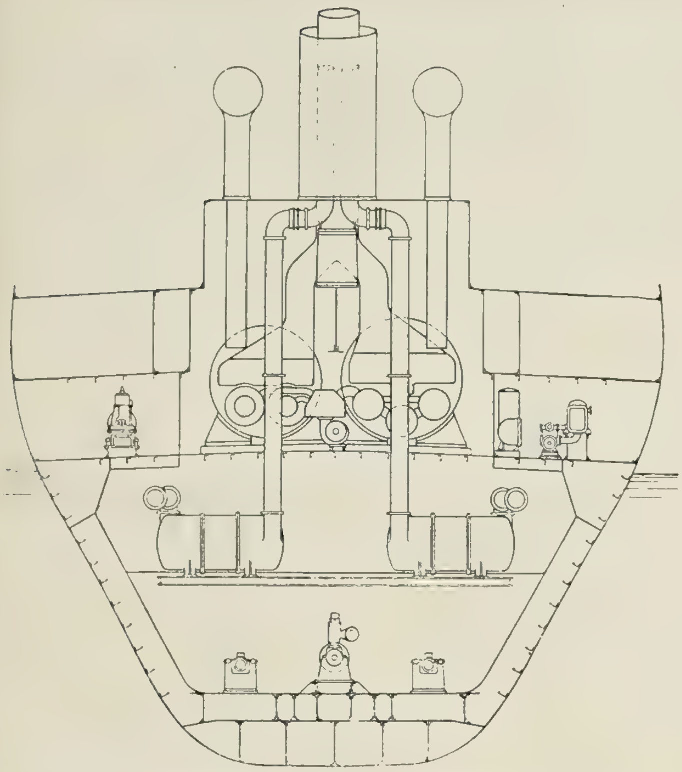
heads have horizontal plating and reinforcement and in the case of the transverse bulkheads 3 additional web frames are arranged on each side of the vessel. The longitudinal frames terminate at the transverse bulkheads and are connected by means of large brackets.

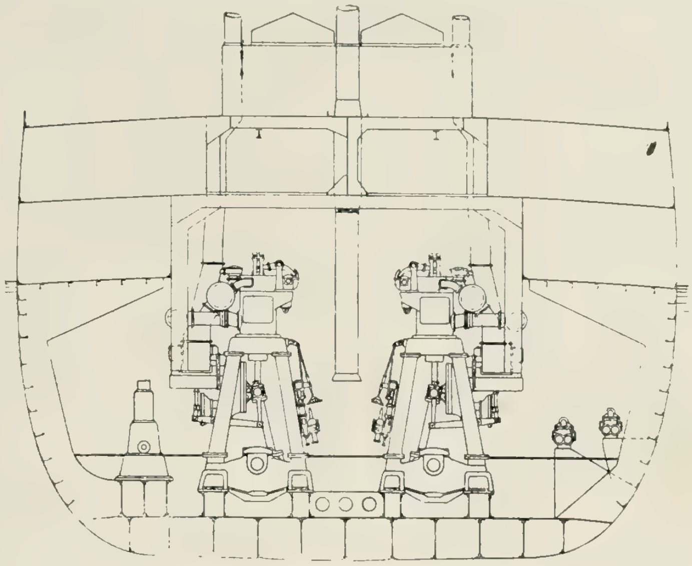
The stern post is notable because the propeller shaft struts are independent of the stern post proper, thereby effecting a saving in the weight of the steel casting.

The rudder is made up of a forged iron rudder stock and rudder-arms, the plate being 1.1 inches thick.

Cargo is discharged by two duplex, compound, steam pumps, 14.17 inches by 21.26 inches by 14.02 inches by 22.05 inches, each with a capacity of 500 tons per hour. These pumps are installed in the pump room. To empty the trimming tanks, the forward cargo hold and the cofferdam behind it, there is installed in the forward part of the vessel a duplex pump of 120 tons per hour capacity.



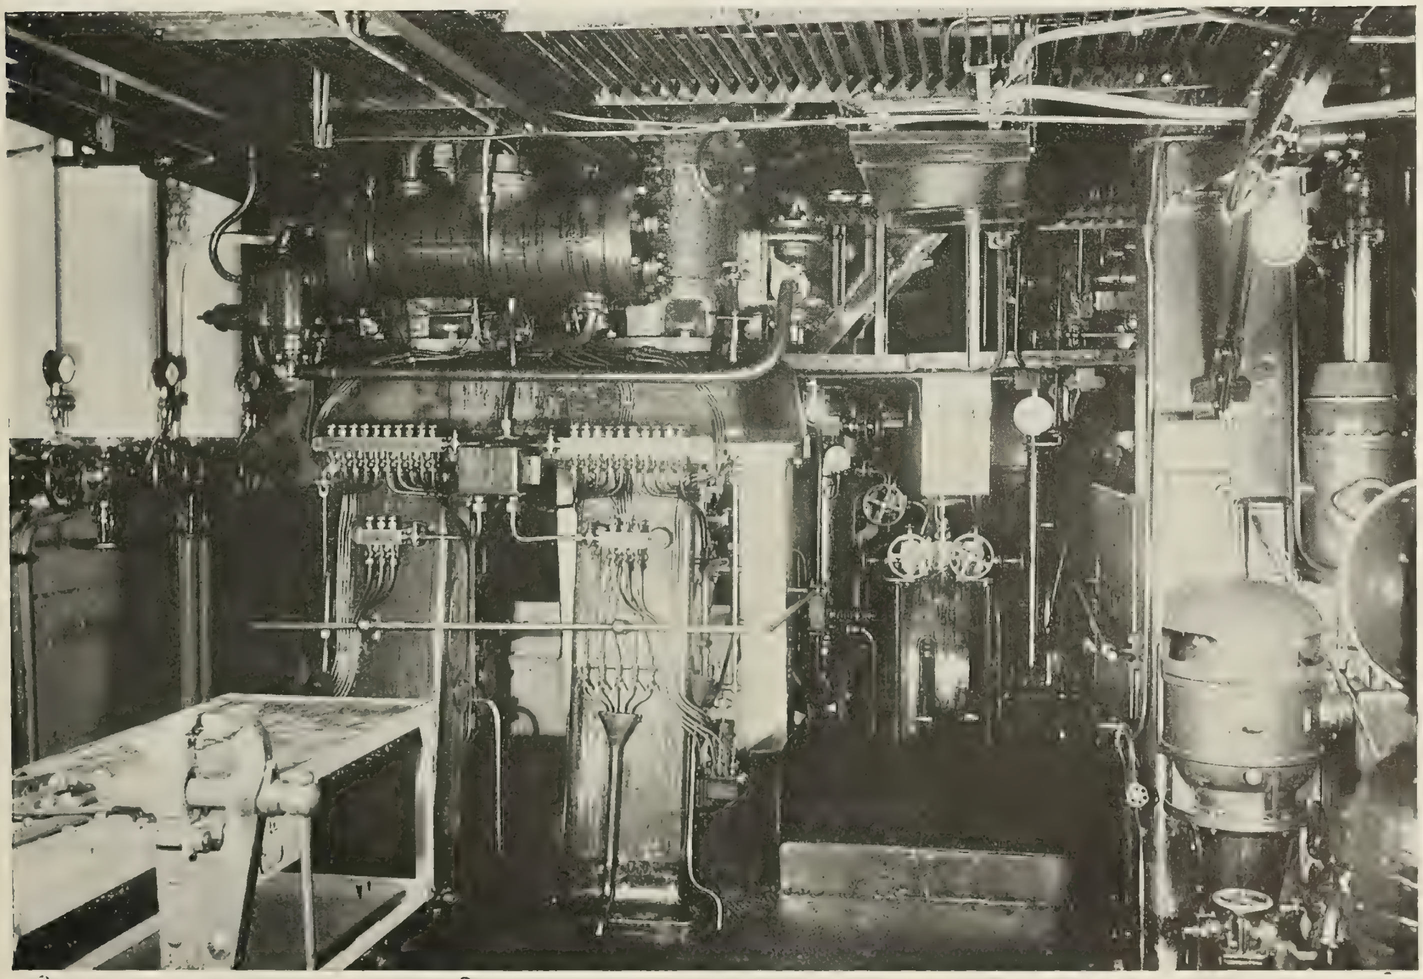
Transverse Section at Frame 24



Transverse Section at Frame 37

The loading and discharging devices, as also the fittings and mountings of the main and summer tanks, conform essentially to those of standard practice.

Two derricks are located forward and two aft at special posts. They serve the loading hatchway forward and the hatchways for stores and food supplies.



View in Engine Room, Showing Diesel Auxiliary Compressors

Quarters for the crew are provided below the bridge and in the after part of the vessel. All quarters are heated by steam as is also the main engine room.

The engine room personnel consists of 1 chief engineer, 2 second and 2 third engineers, 3 assistants, 1 storekeeper, 3 oilers and 3 stokers.

Main Propelling Machinery

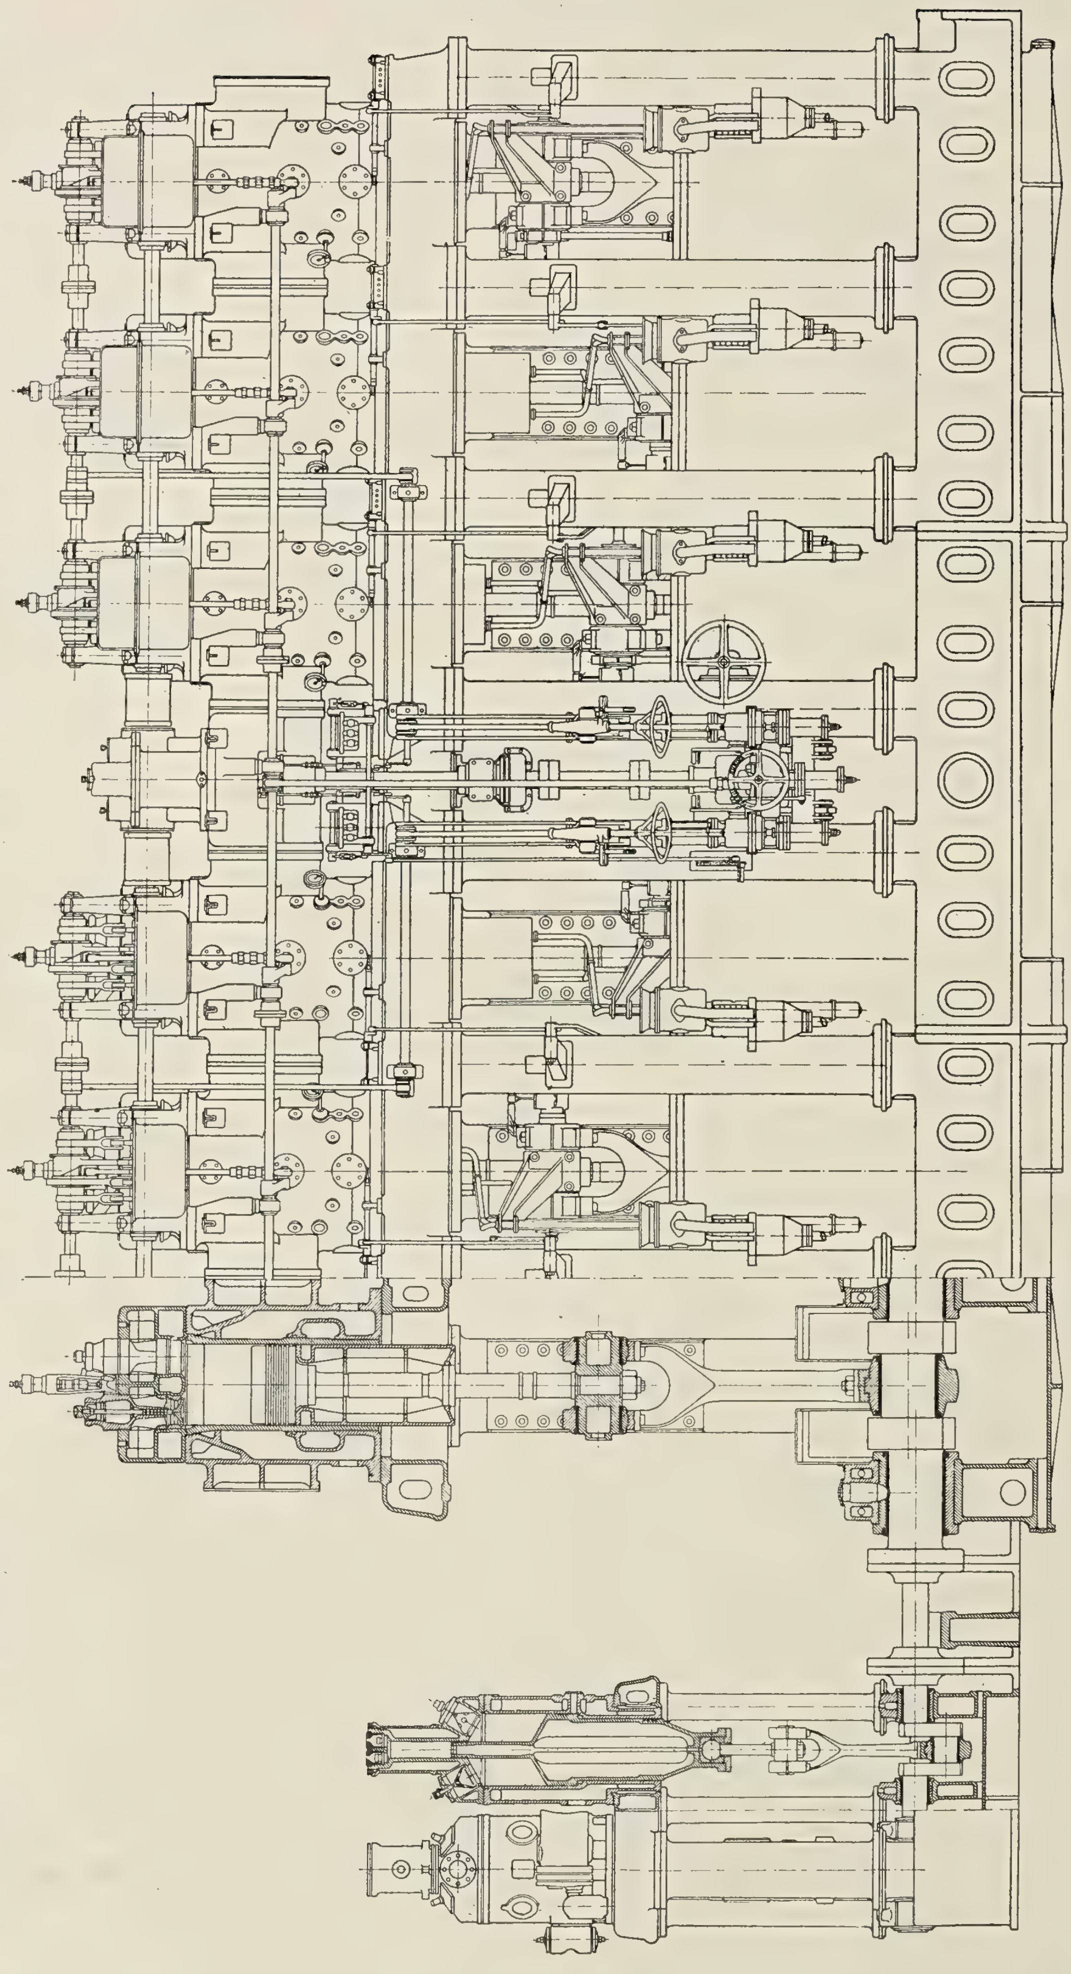
Owing to the easy loading and discharging (from 1 to 2 days) the stay in port for this type of vessel is particularly short and the number of traveling days greater during the year than with other freighters. For this reason, the oil engine plant must be absolutely efficient, the requirement for maximum reliability preceding all others.

The two Germania Diesel engines used to drive the vessel work on the two cycle principle. Their main particulars are as follows:

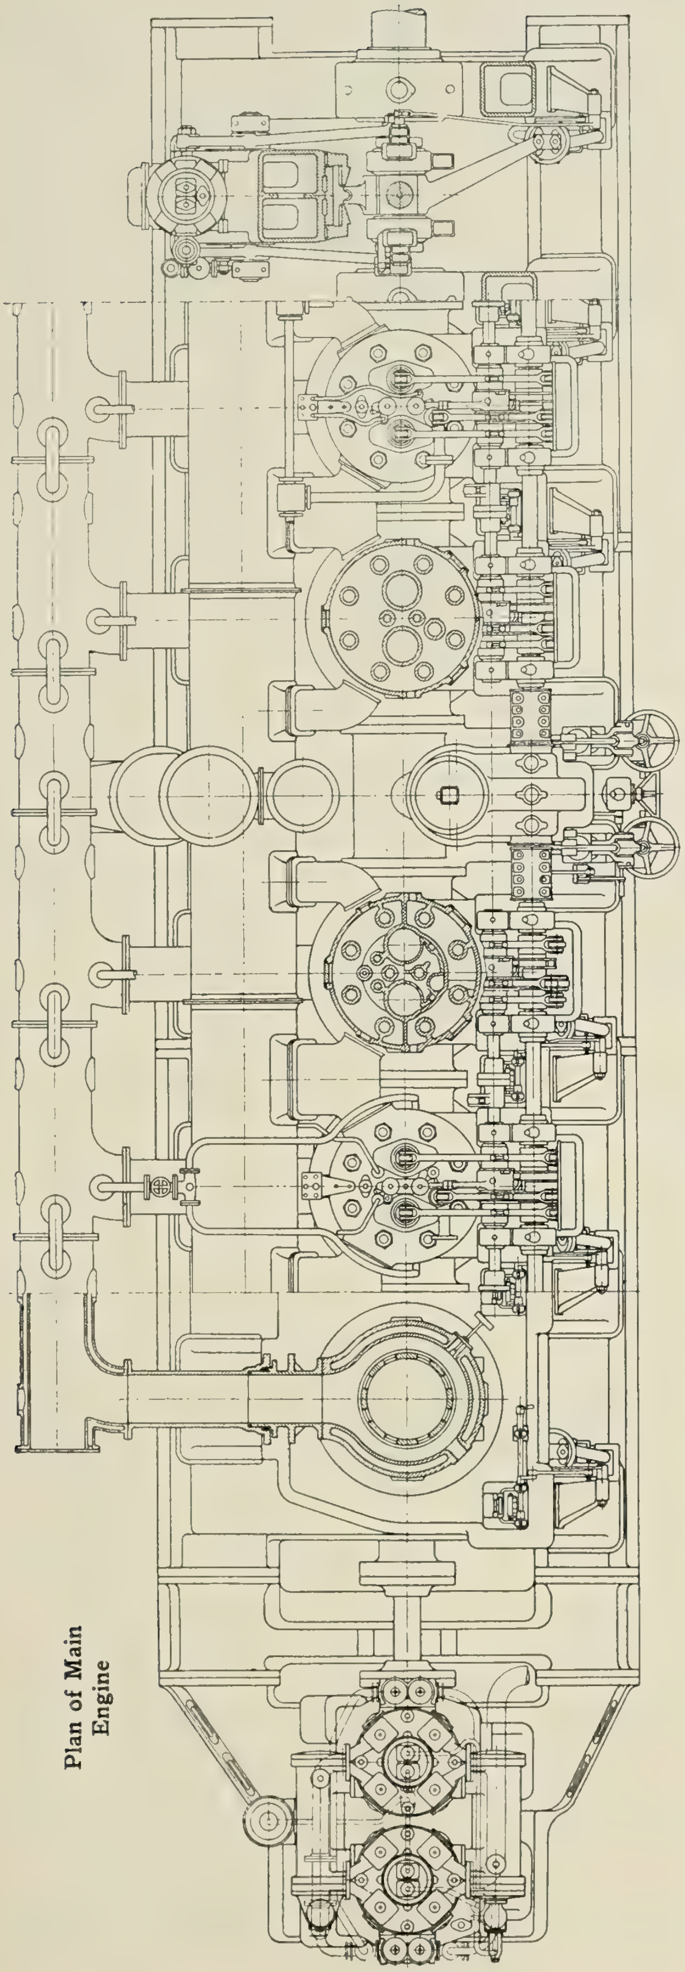
Number of working cylinders	6
Number of compressor cylinders	2
Number of scavenging pump cylinders	2
Diameter of the cylinder	22.638 inches
Normal operating R.P.M.	106
Piston stroke	39.37 inches
Indicated horsepower of both engines, fully loaded vessel, under above operating conditions	2,360
Effective horsepower figured on a mechanical efficiency of 0.71	1,675

The 6 working cylinders are located on a base plate above the columns and connected with each other by strong flanges. The base plate is divided to form 2 three-cylinder blocks between which there is an intermediate piece which takes the upper thrust of the cam shaft, thus assuring the maximum rigidity of the entire engine.

In the cylinders there are fitted special liners



Longitudinal Section and Longitudinal View of Main Engine



Plan of Main Engine

of the type successfully used in submarine boat engines.

In the cylinder cover there are arranged two scavenging and two fuel valves similar to those of the large submarine four cycle engines which proved very satisfactory in service. There are also provided one starting and safety valve with adequate cross section.

Cam and lever shafts are supported in common bearings placed on the rigid cylinder block. In this manner an exact control of the fuel needles is assured and the roller arrangement of the fuel valve lever, which actuates both valves, can be adjusted in operation, regulating the engine in the shortest possible time so that the indicator diagrams, even in long operation, remain unchanged. In this way the load of the individual cylinders can be made very uniform, which is of importance for trips covering weeks of uninterrupted sailing. Each scavenging valve has its own actuating lever.

The working piston consists of an upper part bearing the rings and a casing to cover the discharge ports. The cooling of the pistons is effected by sea water, which is fed and discharged by means of telescopic pipes.

The compressor (injection pump) is driven by the extended crank shaft. There are two similar cylinders with three-stage pistons with the medium pressure piston under the low pressure. The engine has the usual connecting rods with special crosshead guides. The air of the individual stages in both cylinders is cooled off in pipe nest coolers with suitable separators. The valves of the low and medium pressure stages are plate valves and those of the high pressure stages conical valves.

The two double acting scavenging pumps are driven by means of rocker arms from cylinders 3 and 4 and are provided with plate valves.

For driving the rudder engine, a two-stage rudder air compressor driven by a rocker arm from cylinder 6 is provided to supply compressed air at 8 atmospheres.

Two cooling water and bilge and one deck washing pump are driven by the savenging pump rockers and a fuel supply pump is driven by the rudder air compressor rocker.

Lubrication

Forced lubrication of the main bearings is effected by a geared pump driven by the crank shaft. The lubricating oil is supplied from a tank located in the double bottom. The worm wheels and the rocker bearings also receive forced lubrication. Special force pumps are arranged for the lubrication of the crosshead pins. The lower connecting rod bearings are provided with oil cup lubrication which is also provided as emergency lubrication for the main bearings and the crosshead pins.

For cylinder lubrication there are provided special lubricating pumps of simple and very solid construction.

All the oil flowing from the driving mechanism accumulates in the bedplate and flows to a drain tank located in the double bottom.

As reserve for the connected geared pumps there are provided two electrically driven geared pumps.

Maneuvering Compressor

Despite the very liberal capacity of the compressors, which are directly coupled to the main engines and which at full speed are able to develop a 200 percent addition to the quantity of air normally required for the rudder engine, an additional special Diesel auxiliary compressor is installed. This Diesel auxiliary compressor supplies, at 240 revolutions per minute, three-quarters of the maximum quantity of air delivered by a main compressor. It is used in long continued maneuvering with a low number of revolutions of the main engine and long stops. It also serves as reserve for the directly coupled compressors. The three-cylinder, single acting, four-cycle, driving engine corresponds to a medium

speed motor type, without piston cooling, which has proven very satisfactory and which has been frequently manufactured for shore plants.

Auxiliary Machinery

The auxiliaries on a motorship and particularly on a motor tank ship claim special interest. Steam operation of the auxiliary engines has been selected for the *Zoppot* for river navigation and port service, and in view of the justly strict regulations in ports where petroleum and benzine are handled, this solution offers the greatest safety.

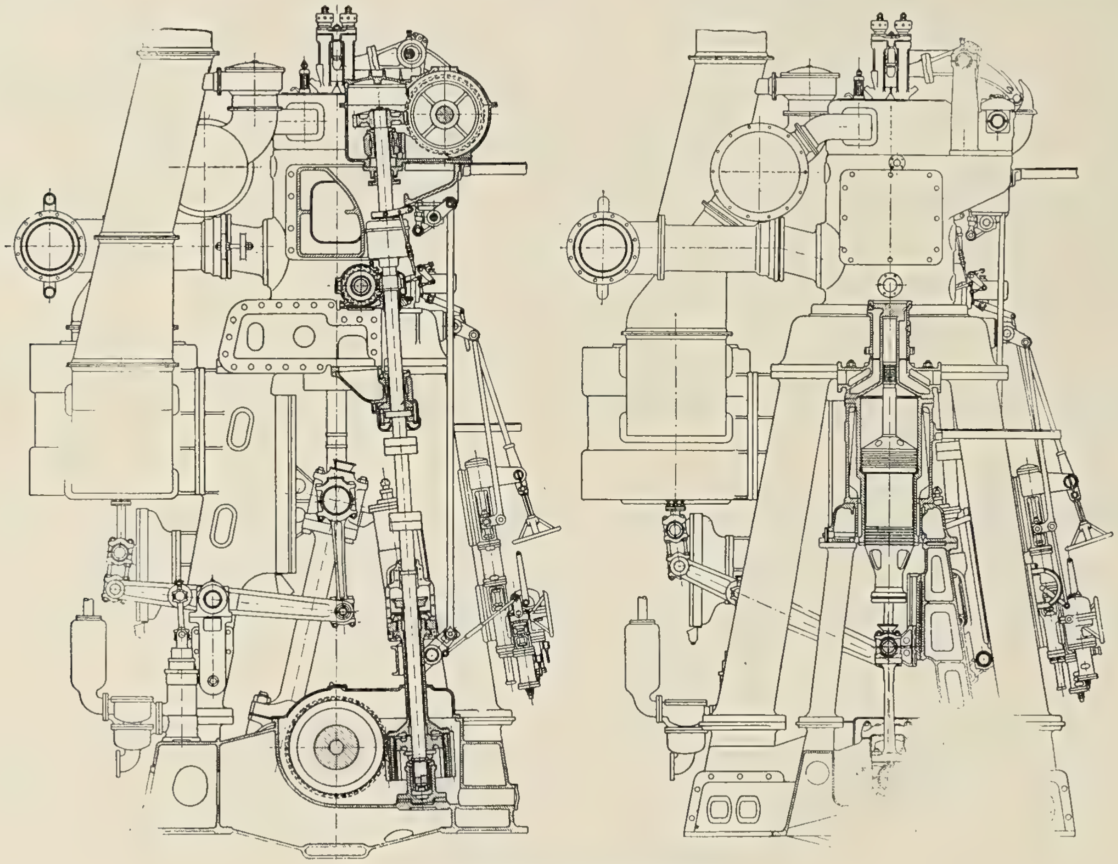
Steam is produced in two auxiliary boilers with oil fuel. The fuel oil is vaporized by pump pressure without the assistance of air or steam. The starboard boiler has two and the port boiler three furnaces. Each furnace is fitted with a centrifugal vaporizing nozzle. The fuel oil is forced through one of the pumps, installed in the engine room to supply the fuel oil settling tanks, to a consumption tank whence the oil flows to a small duplex steam pump, or an injector, which forces it to the vaporisers through a filter and heater. For petroleum loading ports in which no boiler fire is permitted, the steam required is supplied to the auxiliary engines through a special piping connection from shore.

The auxiliary engines of the vessel such as the windlass, warping engines, etc., which are not used on the open sea, are also operated by steam.

The rudder engine is operated at sea with compressed air and in river navigation, where the boiler must be in operation, steam is used. The compressed air for the rudder engine is supplied by a two stage compressor which is attached to one of the two main engines and operated by a lever. The air is stored in a special rudder air container in order to mitigate the pressure fluctuations when shifting the helm. In addition to the provision for switching the rudder engines from air to steam, which is effected at the engine itself, arrangements are made so that compressed air can also be used to drive all steam auxiliaries. This is important in cases of emergency when there is not sufficient time to get up steam. Even the large oil loading pumps have been successfully supplied with compressed air in continuous operation, this compressed air having been supplied by the auxiliary compressor of the Diesel plant. The hand and steam steering apparatus is arranged on the shelter deck in a special wheel house. It has a quadrant, which is coupled with the tiller by means of springs, as well as a rudder brake. The rudder engine is driven by means of a telemotor from the bridge.

To produce the electric current of 110 volts, for power and illuminating purposes, 2 equipments are provided:

1. A dynamo, operated by a 40 horsepower, crude oil engine at 320 revolutions per minute, which is installed in the engine room and
2. A dynamo operated by a two-cylinder compound steam engine of 40 horsepower at 250 revolutions per minute. With the free end of the dynamo shaft an emergency compressor can be coupled, serving to fill the air flasks in case the supply of air should be entirely exhausted. This engine is installed on the second deck adjacent to the boilers.



Cross Sections of Main Engine

The additional pumps installed in the engine room are as follows:

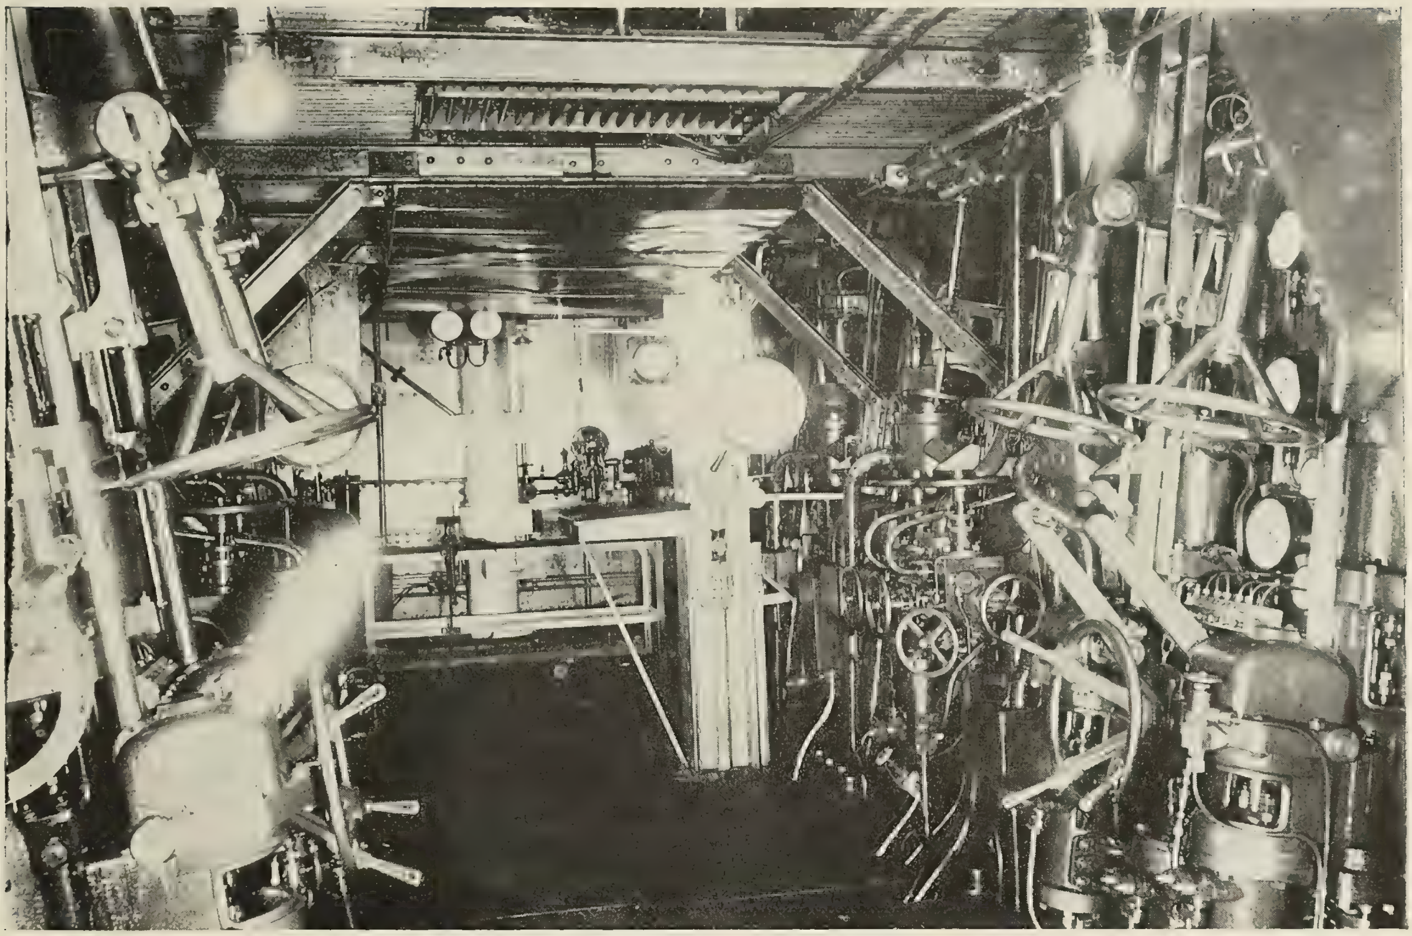
Two duplex steam pumps, also equipped for compressed air, for pumping ballast and to act as an addition for cylinder cooling. Capacity of each pump, about 120 tons per hour.

One electrically driven, centrifugal ballast pump.

One electrically driven, centrifugal pump of 35 tons per hour capacity, against a head of 196 feet 10 inches, used chiefly for deck washing purposes.

Two vertical, electrically driven, reserve geared lubricating oil pumps for the main engines with a capacity of 10 tons per hour against a 65-foot 7-inch head.

The exhaust steam of all auxiliary engines operated by steam is led to an auxiliary condenser of 592 square feet cooling surface located on the second deck. The auxiliaries



Operating Station in Engine Room

can also be operated non-condensing, in order to render possible mixed air and steam operation during the change from one to the other.

On the second deck, alongside the condenser, is an evaporator with a capacity of 15 tons per 24 hours.

Besides the customary apparatus to transmit orders such as the engine telegraph, including reserve telegraph, rudder telegraph, speaking tubes, etc., there is also a system of loud-speaking telephones which connect the bridge, engine room, boiler room and wheel house. This system has proven very satisfactory.

Fuel Oil

Fuel oil amounting to 900 tons is carried in transverse bunkers forward of the engine room and two tanks built into the structure on the second deck outboard of the engine casing. A small portion of the fuel oil is also carried in the double bottom below the engine room.

Two settling tanks with a capacity of 17 tons each are provided. The settling tanks are served by either a small electrically driven piston pump with a capacity of about 20 tons per hour against a head of 98 feet 5 inches or a duplex steam pump with a capacity of 120 tons per hour.

Operation

The trials of the *Zoppot* were held in July, 1920, and resulted very satisfactorily. Data collected at the trials are as follows:

Vessel loaded so that propellers remained 20 inches under water.
Engines worked quietly with no noticeable vibration amidships.
Average indicated pressure 5.5 atmospheres.
Total indicated horsepower, 3,800.
Injection pressure, 55 atmospheres.
Scavenging pressure, 0.15 atmosphere.
Lubricating oil pressure, 0.7 atmosphere.
The high pressure air left the injection pump with a temperature of 20 degrees C., the various cylinder cooling water outlet temperatures fluctuated between 30 and 35 degrees and that of the piston cooling amounted to 40 degrees C.

A slow test trip was made and the engines were reduced to 50 revolutions per minute when using 6 cylinders and 37 revolutions per minute when using 3 cylinders.

The vessel started on its maiden voyage to New York on July 31, 1920.

During the maiden voyage the daily average revolutions per minute fluctuated between 94 and 103. The lowest ship's run for 24 hours was 237 sea miles, corresponding to 9.7 sea miles speed, and the highest 265 sea miles corresponding to 10.9 sea miles speed per hour. The average speed was 10.53 sea miles with a total distance of 3,838 sea miles and the fuel consumption was as follows:

95 R.P.M. — 3,100 I.H.P. = .329 lbs. per I.H.P. hour
99 R.P.M. — 3,500 I.H.P. = .306 lbs. per I.H.P. hour
105 R.P.M. — 4,000 I.H.P. = .300 lbs. per I.H.P. hour

The reduction in the fuel consumption with increasing power, despite simultaneously increasing length of the operating period, showed that the machines were far from their overload limit and that the combustion always remained entirely satisfactory. Both these factors are of the greatest importance to the life of the engines in practical operation. The actual power limit of the engines is very much higher. In former tests on land, continued power of 6,200 indicated horsepower was obtained.

Since then the *Zoppot* has been in continual service with the exception of a 21-day stay at Ponta Delgada, where after towing in the S. S. *Baltic*, it had to wait for fuel oil, and a stay of 19 days in New York for the installation of heating coils in the cargo oil tanks.

Externally the *Zoppot* has no essential characteristics different from those of a steamer as a funnel of normal size

is fitted through which the exhaust pipes and the smokestack of the auxiliary boilers are led. The smokestack, during the time it is in operation, has an easily installable spark catcher which is used in oil ports where boiler operation is permitted only if certain measures of precaution are observed.

Two masts are fitted and aside from fulfilling their signal duties, they serve for the suspension of the antennæ for the wireless equipment. Lightning arresters are provided on the masts.

Four lifeboats and a small boat, 18 feet in length, are carried and suffice for a crew of not less than 62 men.

Independence Tests Her Oil Burners

The electric drive cargo ship *Independence* made a special trial trip on January 6 for the purpose of determining the evaporative power of her boilers and the efficiency of her oil burners. This vessel, owned by the Shipping Board, which was recently converted into a turbo electrically driven ship at the Tebo Yacht Basin of the Todd Shipyards Corporation, has a deadweight capacity of 11,868 tons on a length of 440 feet. Mr. H. B. Taylor, chief turbine engineer for the United States Shipping Board, was in charge of the trial.

It was the purpose of the trial to determine the steaming power of the boilers rather than the efficiency of the turbine and electrical equipment and, therefore, steam was admitted to all the auxiliary lines including those to the deck winches. Steam also escaped from the safety valve continuously so that any figures given for the consumption of steam by the turbine would be erroneous and misleading. However, it should be noted that the propelling machinery worked with precision and gave no trouble.

The vessel is equipped with three single-ended Scotch boilers fitted with the Peabody-Fisher oil burners, high degree firetube superheaters and Diamond soot blowers. CO_2 recorders for determining the quality of the combustion are also fitted.

The Oil Burners

The oil burners are of the mechanical atomizer type. A special feature of this burner is its power, through a by-pass adjustment, of maintaining the whirling motion which atomizes the oil in the central chamber of the tip undiminished whatever may be the capacity desired of the burner. This is accomplished by diverting or by-passing a part of the oil supply from the central chamber and returning it to the pump suction. In this method the amount of oil which is sprayed into the furnace depends on the proportion of the oil that is by-passed to the total amount entering the burner. With this system the amount of oil entering the central chamber is always the same, so that the whirling of the oil and the atomizing effect remain constant, securing a good spray over a wide range of combustion.

It will be seen from the accompanying table that 55,400 pounds of water were actually evaporated per hour from 1:45 to 4 o'clock and that during this time 4,500 pounds of oil per hour were consumed. This gives an actual evaporation of approximately 12.32 pounds of water per pound of oil but it is to be noted that the temperature of the feed water was only 170 degrees. This low temperature of the feed water was caused by the arrangement of the measuring tanks which were installed on the boat deck. The evaporation per pound of oil from and at 212 degrees Fahrenheit was therefore about 14.85 pounds of water per pound of oil.

Still further, an analysis of samples of the fuel oil showed that there were only 17,931 British thermal units as compared with an average value of 18,500 British thermal units for good oil. With oil having a thermal value of 18,500, the evaporation from and at 212 degrees Fahrenheit would be 15.33 pounds of water per pound of oil, which would give the boiler an efficiency of 80.4 percent.

In connection with the superheaters, attention is called to the high degree of superheat maintained. It is also to be noted that the results obtained in boiler evaporation were materially better after the tubes had been blown than they were in the earlier part of the run. The writer was not at all surprised at this after witnessing the amount of soot escaping from the front of the fireroom while one boiler was being blown and the dense clouds escaping from the stack while the process was going on in the others.

It is estimated that an evaporation of 45,000 pounds of water per hour is sufficient for the requirements of the turbine at full load. During the test, as will be noted, the water actually evaporated was 55,400 pounds per hour. The oil consumed was measured by meter readings and by actual soundings taken from the service tanks. From the official soundings taken during the afternoon the average consumption of oil was found to be 4,500 pounds per hour. The results of the test are shown in the following table:

PERFORMANCE OF PEABODY-FISHER BURNERS. TEST ON S. S. INDEPENDENCE, JANUARY 6, 1922

Factor of evap.—1.205. Boiler efficiency—82.5% (official).

*The low feed temperatures were caused by the arrangement of the measuring tanks.

Oil Engines Versus Steam for Tugboats

By H. A. Christensen

With a general depression in shipping and thousands of ships being laid up all over the world, a remarkable strength and steadiness has been shown by the motorship, since practically all ships of that type are still in commission and earning good money for their owners. This condition refers not only to ocean-going vessels, but also to the small, but not less important, craft that keep things moving in harbors, rivers and canals. Since numerous articles have lately been written about ocean-going motorships, this article will deal with the development of oil-engined tugboats.

INLAND water transportation has shown a much steadier condition during the general depression than has trans-oceanic traffic. In fact a substantial increase in inland water transportation seems imminent. The Ford Motor Company, it is reported, is planning to distribute its product by oil-engined craft and many more will follow suit as soon as the economy of such vessels becomes generally known.

Good examples have been set along these lines by such countries as Holland, Germany and France, where efficient water transportation is of the utmost importance. In spite of the fact that these countries have to import practically all their fuel oil, they have long ago adopted the crude oil motor as the motive power for river and harbor vessels. Although

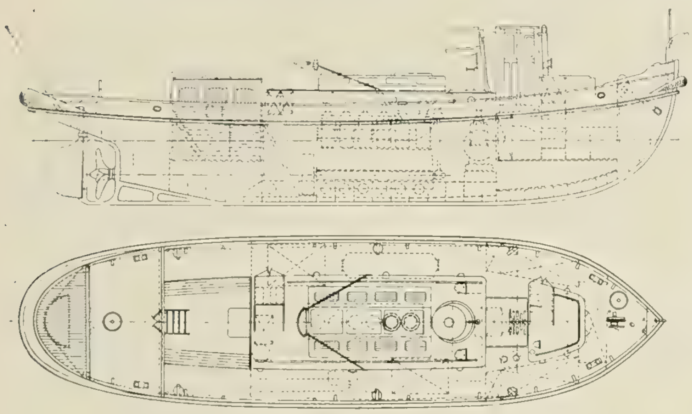

Fig. 1

America is the greatest oil-producing country in the world, we have not yet taken the lead in this respect. The reason is that, during the war, when anything that would float could be operated at a profit, nobody had time to make any changes in their propelling machinery. But conditions have now changed. It will be the owner who has made a thorough study of his problem and who has adopted the most economical form of motive power that will be able to operate his boats at a profit, while competitive boats are laid up.

Advantages of Motor Tugboats

From actual working data of existing motor tugboats the following advantages for the oil engine have been established:

1. As for large ships, the fuel consumption being between 0.4 and 0.5 pound per brake horsepower hour, the cost of fuel is well below one-half the cost of a steam installation.
2. The weight of an oil engine installation is less than that of a steam installation. This means that the dimensions of the oil-engined tug can be reduced, compared with the dimensions of a steam tug of the same horsepower. This of course means a cheaper boat.
3. Stand-by losses are eliminated in oil-engined tugs, since it takes only a few minutes to start up the oil engine, whereas a steam tug must have the fires burning continuously.
4. Compared with a steam tug of the same dimensions and horsepower the oil-engined tug can carry more fuel and will thus have a greater cruising radius, due to the lighter engines.
5. No firemen are required on an oil-engined tug, giving a saving in the crew's wages.

We shall now describe a few representative tugboats that will substantiate the claims just brought up.

German Motor Towboat

Fig. 1 shows a Diesel tugboat for harbor service that has been in use at the Government shipyard at Wilhelmshaven, Germany, for over three years. The boat was built by the Hitzler Shipyards at Lauenburg, Germany.

The principal dimensions are:

Length overall	52 feet 6 inches
Length between perpendiculars	45 feet 11 inches
Beam	13 feet 1½ inches
Depth	6 feet 3 inches
Draft	4 feet 7 inches

A steam tug with the same horsepower would require an addition to the length of about 3 feet and an addition to the beam of about 1 foot due to the larger weight of the steam outfit. This boat is built to the German Lloyds rules and is also designed as an icebreaker.

In order to enable the boat to pass under bridges, the superstructure as well as the smokestack was kept low. Four watertight bulkheads divide the boat into fore peak, crew's quarters, engine room, cabin and after peak.

Instead of a towing engine or towing bitt, as used on many American tugs, a towing hook is used. This hook is located near the center of gravity of the boat, which makes steering easier. This is the more important as most of the towing in Europe is done with the lighters astern of the tug and the practice of making fast alongside of the lighter is hardly ever used.

The machinery consists of one direct reversible two-cycle Diesel engine of 100 brake horsepower. The engine makes 250 revolutions per minute, although it will run smoothly at 70 revolutions.

The engine has four working cylinders, each provided with an independent fuel oil pump and two air pump cylinders placed on the centerline of the engine. The engines are reversed by compressed air from the air tanks, which are of sufficient capacity to reverse the engine twenty times without requiring refilling.

The auxiliary air compressor is driven by a 5 horsepower hot bulb engine that also handles the bilge and fire pump. The cylinders are water cooled by a pump, driven directly from the crank shaft.

The fuel consumption of the main engine using fuel oil of a heating value of about 18,000 British thermal units per pound has averaged 47.4 pounds per hour. The boat can carry fuel oil sufficient for a trip of 500 sea miles. A steam tug of the same size can carry only a few tons of coal, sufficient for about 175 sea miles, on account of the heavier steam installation.

The time used for reversing on the trial trip was about six

seconds from full speed ahead to full speed astern, and the average speed was nine knots.

American Motor Tug

The *Marie L. Hanlon,* one of the first American motor tugs, is shown in Fig. 2. She was built in 1913 by D. J. Hanlon of Oakland, Cal., and is fitted with one direct reversible Bolinder engine of 160 horsepower and 224 revolutions per minute.

A very close comparison with a steam tug could be made in this case as the owner had a steam tug of the same dimensions:

Length overall	71 feet 5 inches
Beam	17 feet 5 inches
Depth	8 feet 5½ inches
Draft, average	6 feet 6 inches

The steam installation consisted of a Scotch boiler 7 feet 6 inches in diameter and 9 feet long and a compound engine 10 inches by 20 inches by 18 inches. On account of her large engine space the steam tug carries only 18 barrels of oil, which, on a fuel consumption of 42 gallons an hour and a speed of 10½ miles, gives her a steaming radius of only 189 miles. Her sister ship carries 38 barrels of fuel oil and with a fuel consumption of 13.7 gallons per hour she has a radius of 1,565 miles.

The machinery weights in this case are given as 450 pounds per horsepower for the steam installation and 170 pounds for the motor.

The lower fuel consumption and the elimination of the fireman are claimed to bring the operating expenses of the motor tug down to about one-half those of the steam tug.

Danish Motor Tugboat

Fig. 3 shows a Danish wooden tugboat for harbor service. This boat has been in use in the harbor of Copenhagen for the past two years. Its principal dimensions are:

Length overall	52 feet 6 inches
Length between perpendiculars	47 feet 0 inches
Beam	13 feet 0 inches
Depth	7 feet 6 inches
Draft	4 feet 9 inches

This boat is provided with an 80 horsepower Volund hot bulb reversible engine which makes 250 revolutions per minute.

The fuel consumption of the engine with Solar oil of 18,000 British thermal units heating value is about 43 pounds per hour. The weight of the engine is 180 pounds per horsepower, and it takes exactly eight minutes to start it, from the moment the blow lamps are lighted.

The crew consists of three men and the boat makes an average speed of 9 sea miles an hour.

The absence of auxiliaries and the simple construction as well as lower weight of these engines compare very favorably with Diesel tugs of the same size, whereas the Diesel even in the small sizes has the advantage of a slightly lower fuel consumption. The first cost of a hot bulb engine is lower than that of a Diesel engine.

A steam installation in a boat of this size would take up more than half of the crew's quarters and it would also necessitate a larger deck house.

French Motor Tugboat

Fig. 4 shows a powerful Diesel-engined tugboat built for service on French rivers. Not less than sixteen of these tugs were built during the war by the French Government.

The principal dimensions are:

Length overall	91 feet 10 inches
Length between perpendiculars	85 feet 3 inches
Beam	16 feet 8 inches
Draft	9 feet 10 inches

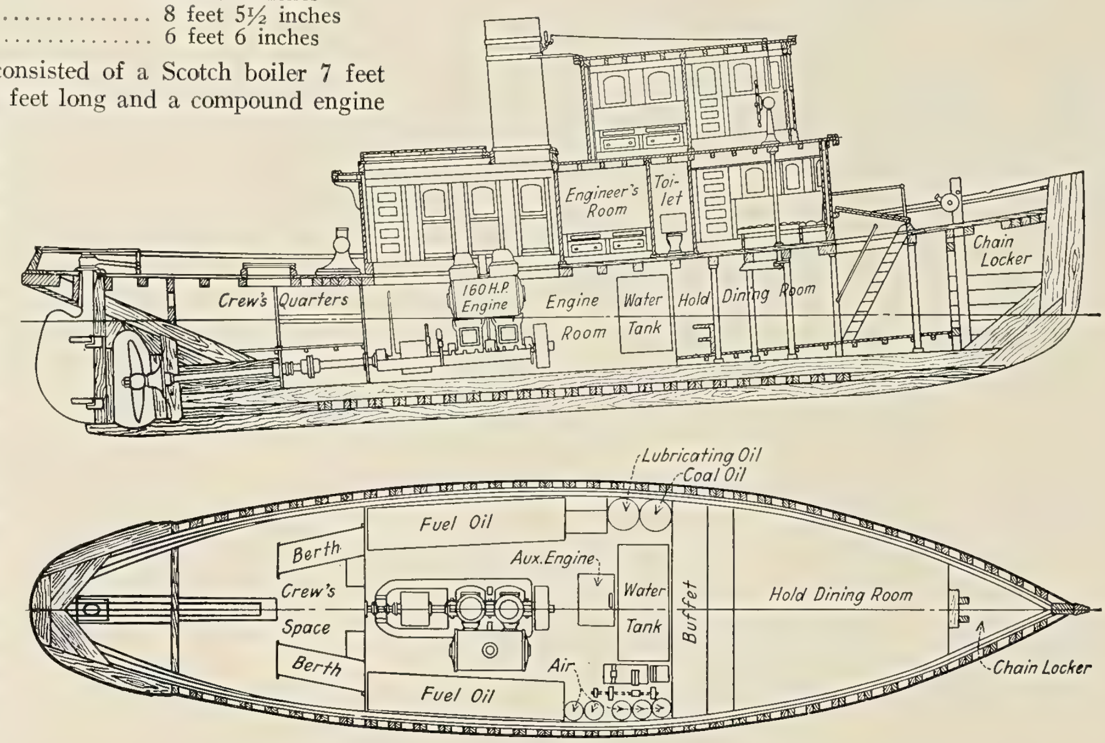

Fig. 2

Displacement	143 tons
Fuel capacity, about	10½ tons

Ten of these boats are propelled by two-cycle Diesel engines of 420 brake horsepower making about 220 revolutions per minute. The fuel consumption of these engines is 0.38 pound of crude oil per brake horsepower hour. The auxiliary air compressor and the electric lighting are handled by a 12 horsepower Diesel engine. The engines are of the Sulzer design, built by the Forges et Chantiers de la Mediterranee, Paris.

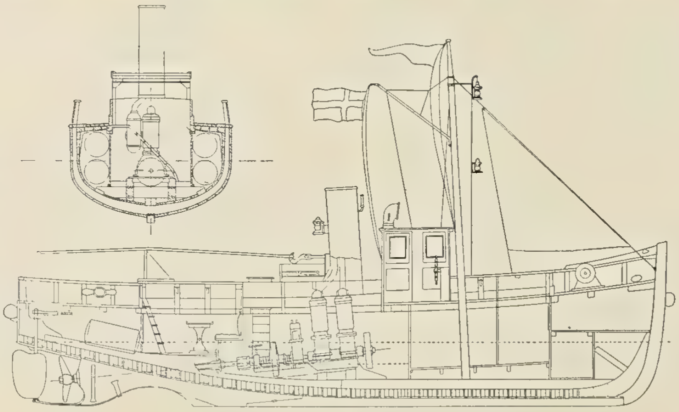

Fig. 3

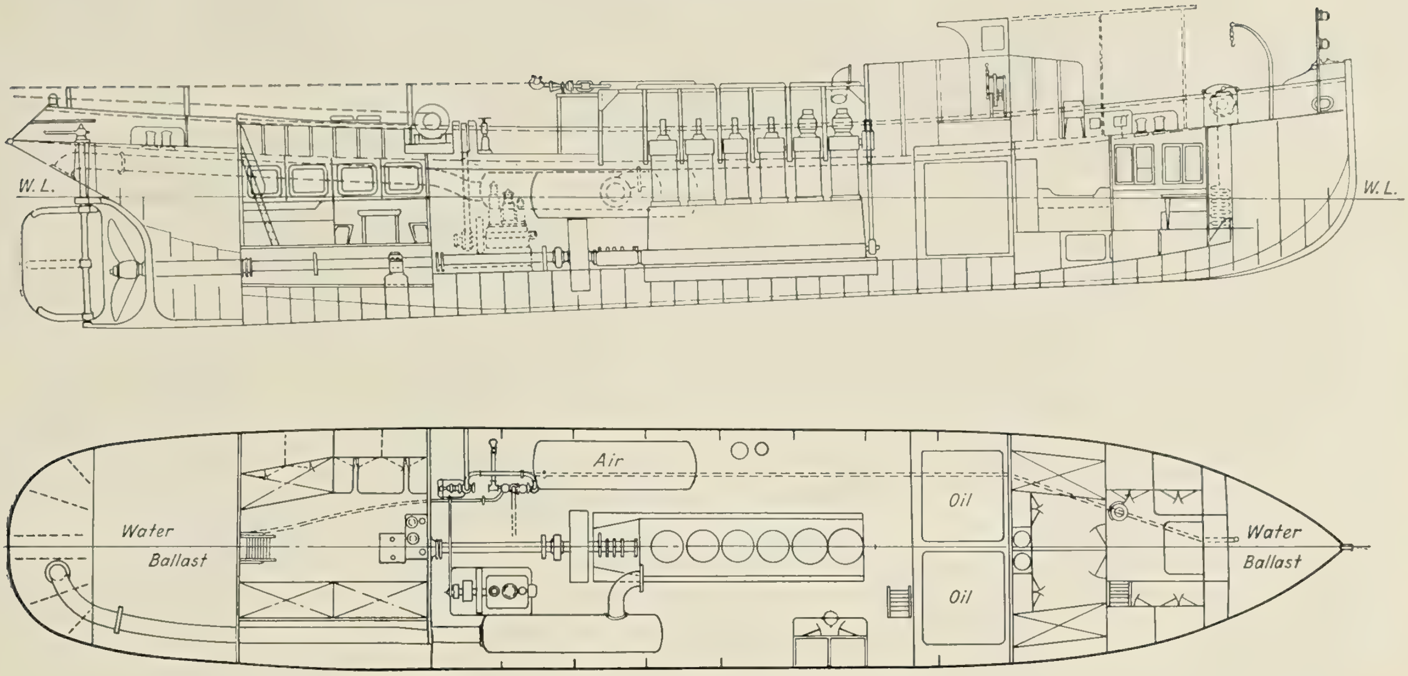

Fig. 4

Six of the boats are propelled by 350 horsepower Polar Diesel engines making 200 revolutions per minute. On account of the smaller engines on these boats their displacement has been decreased by about five tons.

German Motor Tugboat

Fig. 5 shows an ocean-going tug, two of which were built in 1916 by the Atlaswerken in Bremen, Germany.

The principal dimensions are:

Length overall	77 feet 7 inches
Length between perpendiculars	69 feet 6 inches
Beam	18 feet 0 inch
Depth	11 feet 2 inches
Draft, aft	9 feet 6 inches

The boats were designed for ocean as well as for harbor service. They carry 17.7 tons of fuel oil, giving them a radius of about 2,500 miles. A steam tug with its heavier engine and with the same amount of fuel would require much larger dimensions.

The propelling machinery consists of one two-cycle Diesel engine of 350 horsepower, with 180 revolutions per minute. The steering engine, the windlass and the whistle are handled by compressed air from an air compressor driven by a 30 horsepower Diesel engine. According to the German Lloyds rules the boats also have an auxiliary air compressor driven by a 5 horsepower hot bulb engine.

The smokestack is provided with a number of baffle plates that continuously change the speed and direction of the exhaust gases, thus considerably reducing the noise from the exhaust.

These tugboats, one of which has been in service for seven years, have rendered excellent service. No large repairs have been required during that time.

The engines were built by the firm of Benz & Cie., Manheim.

Swedish Motor Salvage Vessel

Fig. 6 shows the Swedish salvage vessel *Fritiof*. Although she is built for salvage work, she possesses all the features of a large ocean going tugboat.

The principal dimensions are given on the following page.

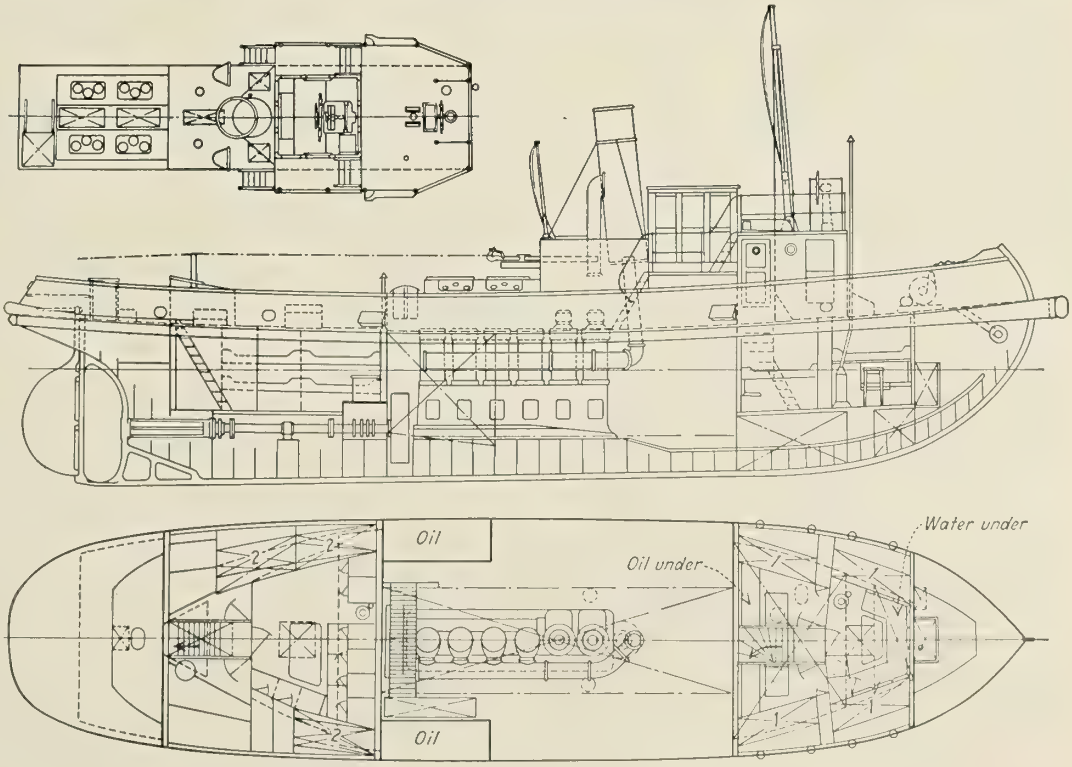

Fig. 5

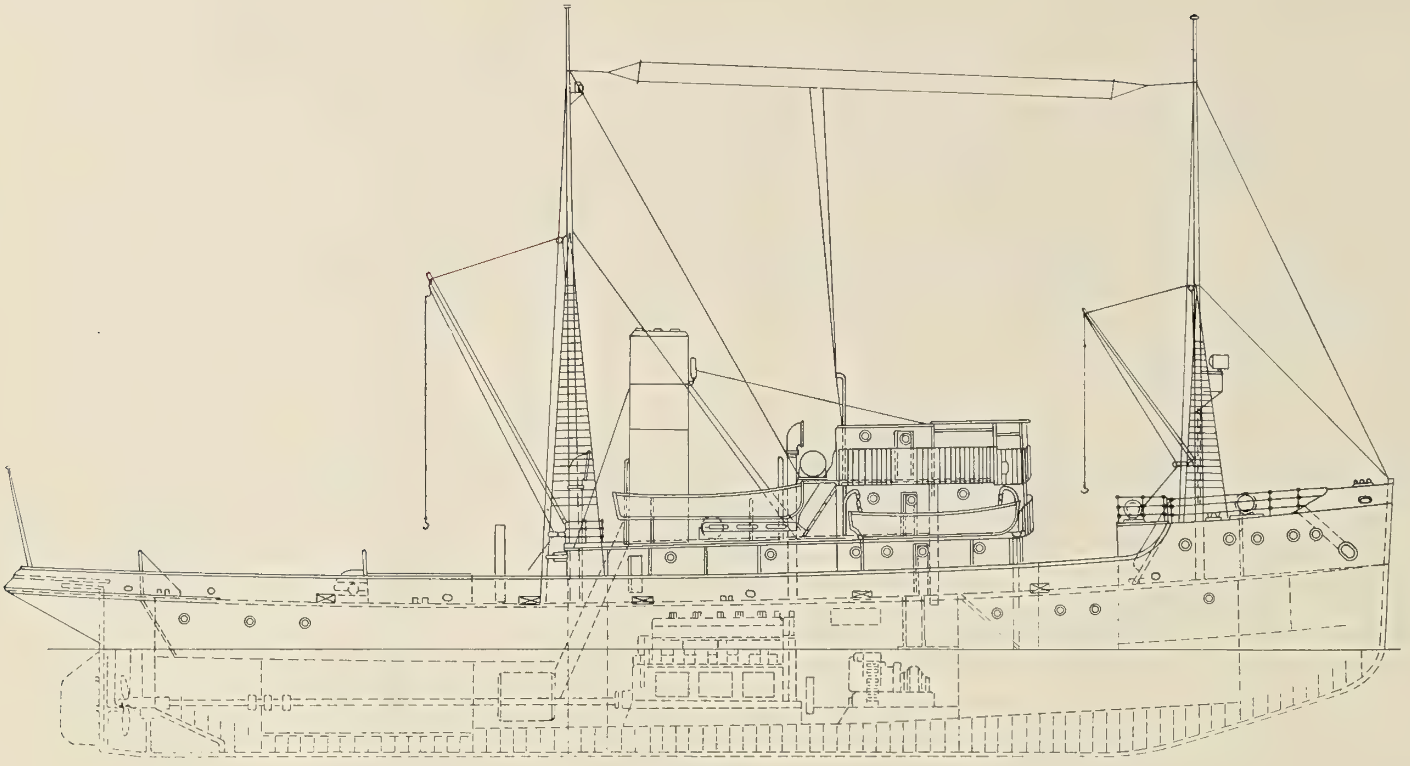

Fig. 6

Length between perpendiculars	156 feet 11 inches
Beam	34 feet 9 inches
Depth	18 feet 7 inches
Draft	13 feet 5 inches

The machinery consists of two four-cycle Diesel engines of 625 horsepower each, of the Burmeister & Wain type built by Gotaverken, Sweden, and three Diesel engines of 90 horsepower each coupled with a dynamo. Besides the usual auxiliary equipment for a Diesel installation, there are two 14-inch salvage pumps, three 8-inch portable pumps, one 12-inch steam driven pump and two portable plunger pumps. The steering engine, the cargo winches and the towing engine are steam driven. Steam is supplied by one Scotch boiler and one portable boiler.

Built as an icebreaker and with a forecastle giving added seaworthiness she can be looked upon as an excellent all round type of a large ocean going tug.

The principal reason for using motors in this case has been the fact that she will be ready to start on a trip at short notice, a fact that greatly increases her value for salvage purposes. She can also carry more fuel than a steamer of the same dimensions, which is especially important for long distance towing.

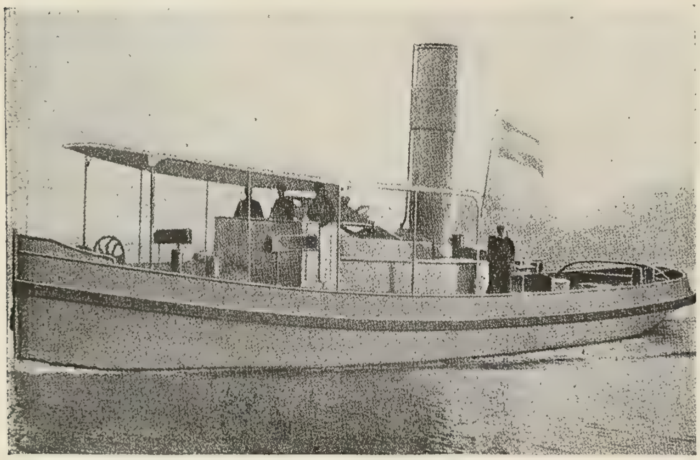

Fig. 7.—East Indian Harbor Motor Tug

East Indian Motor Tugboat

A small tug for harbor service in the East Indies is shown in Fig. 7. It was built by the shipyard of Nicolaas Witson, Alkmaar, Holland, and is 59 feet 9 inches long between perpendiculars with a beam of 14 feet 9 inches.

The boat is propelled by a two-cycle Diesel engine of 160 horsepower at 250 revolutions per minute. A small hot bulb engine of 6 horsepower at 650 revolutions per minute drives a centrifugal pump in the engine room.

As in all Diesel tugs there is ample room for fuel tanks and, with the approximately 1,300 gallons that she carries, this boat can run over 1,100 sea miles without refilling the tanks.

The awnings which cover the entire forward part of the deck and an extra large engine room skylight are special features for service in the tropics.

Conclusion

Judging from the data just shown for various oil-engined tugboats in actual use in the principal maritime countries, this type of tugboat certainly offers many advantages over the steam tug. War conditions in shipping have passed, and we are forced to compete with other nations that are not slow to grasp opportunities to decrease their operating expenses. We Americans, with our higher wages and standard of living, should be interested more than anybody else to find ways and means to remove this handicap by adopting equipment that is equal or better than that used by our competitors.

George E. Bunting, Australasian manager for the Canadian Government Merchant Marine, Ltd., who will act as general traffic agent for the Canadian National Railways, will have general supervision in New Zealand and Australia of the traffic interests of these railways.

Theodore J. Pick, for several years chief clerk of the Terminal Shipping Company, has been appointed operating manager of the Williams Steamship Company in Baltimore.

24182

American Coastwise Motor Tug

By Edward A. Edwards*

THE very remarkable increase in the use of the oil engine for marine purposes during the past eight years has extended to nearly every type of vessel, large and small, in every kind of service and its great advantages over the cumbersome and far less economical steam plant are being recognized by the operators of tugs, lighters and other small craft which play a more humble though none the less important part in our general system of marine transportation. The steadily increasing number of motor tugs going into service is a pretty sure indication that this type is giving reliable and satisfactory performance along with its undoubted superiority in the matter of operating economy.

The plans show a 300 horsepower motor tug designed by the writer for the Diamond P Boat Line of Philadelphia and intended for general coastwise and inland towing. The draft has been limited to 7 feet for canal work but the boat has plenty of sheer and freeboard so that outside trips can be made with comfort and safety.

In order to realize fully the advantages of this tug over a steam vessel of the same power it should be noted that, according to the United States Steamboat Inspection Service regulations now in force, a motor vessel used exclusively for towing purposes requires no inspection and no licensed officers. The captain of a boat of this kind, however, would be a licensed pilot in any case. A single crew for the tug shown here consists of only four men; captain, engineer, deck hand and cook, while a double crew for 24 hour service would ordinarily add two more, a mate and an assistant engineer, although one well known boat of this type has been working up and down the coast for the past two years all the way from Florida to Maine with a total double crew of only five men, one of whom acts either as second engineer or deck hand as occasion demands. A steam tug of this size would have to carry two firemen in addition to the single crew mentioned above, while for the double crew another fireman and another deck hand would have to be employed.

The fuel consumption of the 300 shaft horsepower main engine is approximately 22 gallons per hour at full load, so that with 30 tons of oil in her bunkers this tug can run at full power for over 400 hours. Working 10 hours per day this means that the boat will require bunkering only once in forty days, while in 24 hour service she can be run at full power for 17 days. These figures should be interesting to the owner of the average steam tug which loses practically half a day every five or six days in filling up her coal bunkers.

*40 cu. ft. per ton;..............gals, per bbl.

In addition to the above outlined advantages it should be remembered that the motor tug is always ready for instant service, there being no time loss while getting up steam. In addition there are no stand-by losses, no ashes to handle, no dirt and no choked bilges to clean out.

One of the features of this boat which should have special mention, and which overcomes one of the most frequently raised objections to the motor tug, is the Sperry electro-magnetic clutch which will probably be installed for the purpose of securing added flexibility and maneuvering power. This clutch is a recent development of the Sperry Gyroscope Company and is installed in place of the flywheel on the after end of the main engine, adding practically nothing to the space and very little to the weight. It requires less than three amperes of current at 110 volts to transmit the full power of the engine. The transmission is through an air gap, not by any clamping of plates, thus giving that perfect flexibility which is the main advantage of the electric drive. The current through the clutch coils is controlled by a rheostat placed close to the other engine controls and also in the pilot house if desired, enabling either the pilot or the engineer to bring the propeller shaft from zero up to full revolutions, or vice versa, as gradually as may be desired and with absolute freedom from jar or shock.

Hull

The principal dimensions of the tug are as follows:

Length, overall	82 feet 6 inches
Breadth, molded	18 feet 6 inches
Depth, molded	9 feet
Draft with 28 tons fuel	7 feet
Shaft horsepower	300

The scantlings are in excess of American Bureau or Lloyd's requirements. There are four oil tight transverse bulkheads, two forming the peak tanks and two the main fuel bunkers. The fuel compartment is also divided by a centerline longitudinal bulkhead into port and starboard tanks, the combined capacity of which is 29 long tons. Additional fuel may be carried in the peak tanks and two daily service tanks are located in the engine room.

Machinery

The main propelling unit is a 6 cylinder, 14-inch bore, 18-inch stroke, Fairbanks Morse type C-O direct reversible oil engine, conservatively rated at 300 brake horsepower at 250 revolutions per minute. This engine is of the moderate compression, two stroke type with mechanical injection.

The auxiliaries are all electrically operated and consist of one 4½ by 5 Ingersoll-Rand Imperial Type 14 vertical reservoir cooled air compressor connected by short belt drive to a 5 horsepower, 1,150 revolutions per minute Fairbanks Morse type CPB motor; one 2-inch Blackmer rotary bilge and general service pump geared to a 3 horsepower, 1,150 revolutions per minute Fairbanks Morse type CPB motor and one ¾-inch Blackmer rotary fuel transfer pump geared to a one-half horsepower, 1,750 revolutions per minute General Electric type RC motor. All motors are 110 volt direct current, which is supplied by two 5 kilowatt Winton gasoline engine driven generating sets. One of these sets is sufficient for ordinary use and the other is held in reserve.

A slate panel switchboard with circuit breakers and controls for motors and lights is located above the grating in the upper part of the engine room. There is also a 56 cell, 110 volt storage battery for auxiliary lighting purposes.

Starting and maneuvering air at 175 pounds pressure is carried in two tanks, one on each side of the engine room.

A small coal burning steam boiler for heating purposes is located in the forward starboard corner of the engine room.

The complete tug as shown in the plans can be built, fully equipped and delivered to New York or Philadelphia for approximately $60,000 at the present time.

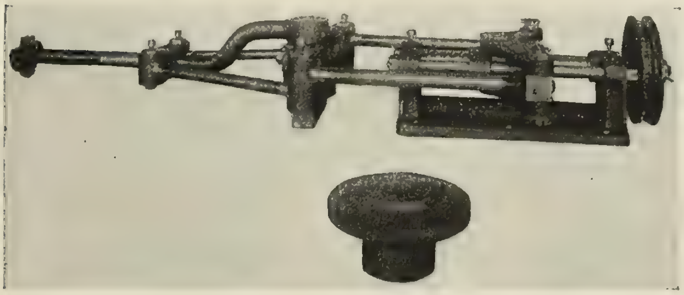
Motorship With a Non-Reversing Engine

Maneuvering Ability Supplied by Kitchen Rudder, the Alca Completes Year of Uninterrupted Service in Congested Harbors

By Alexander McNab*

THE economical advantage of the direct Diesel driven ship is evident by the success already attained. The greatest testimony to ships of this class is the number in successful operation today; voyages are undertaken and

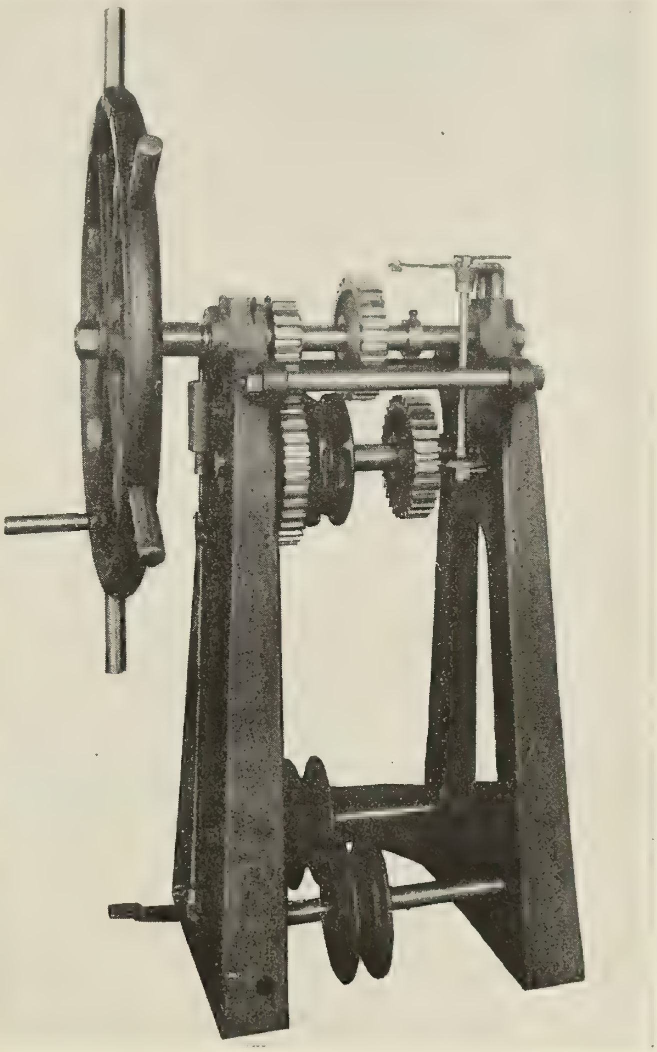
Stern of Motorship Alca, Showing Kitchen Rudder



Steering Gear of Motorship Alca

marine conditions accepted without any trepidation because of the machinery installed.

When Dr. Rudolf Diesel brought out his first engine it was of the land type, being non-reversible. It was therefore natural that marine engineers went to work to make this type of engine reversible before it could be successfully applied to ship propulsion. It may seem preposterous, at this late date, to state that, if more consideration had been given the ship's rudder, there is every reason to believe that the reversing of the reciprocating, turbine or Diesel engine need never have been considered. As a matter of fact, however, vessels



Steering Wheel of Motorship Alca

equipped with Kitchen rudders, which accomplish the reversal of the ship without reversing the engine, are now being successfully operated.

Features of Kitchen Rudder

The essential parts of the Kitchen rudder consist of two curved deflectors, which partially enclose the propeller, both of which are pivoted on top and bottom on common centers. By suitable mechanism, similar in design to the electric-hydraulic type of steering gear, the deflectors or rudders are made to turn together in the same direction or equally in opposite directions. The operation of the rudders is arranged by remote control installed on the bridge, this control can be electric or telemotor.

Over three hundred Kitchen reversing rudder installations have been made and it has been found, from data taken on a

*President of The McNab Company, Member Institute of Marine Engineers.

number of different classes of vessels in operation ranging from the tow boat up to and including the ocean motor freighter, that the maneuvering and steering ability of each ship so equipped is identical.

With this new type of rudder the Diesel engine or steam turbine can be made non-reversible and directly connected to the propeller shaft. During the time that the propeller is rotating full ahead the vessel, fitted with the Kitchen rudder, can be held stationary as if at anchor, can be sent ahead at a speed ranging from the fraction of a knot to maximum speed or can be brought from full speed to dead rest in approximately her own length without shock or strain to rudder, hull or machinery. A single screw ship can be rotated on her own axis to port or starboard without progression, which maneuver is impossible with any other type of rudder, and with propeller running full ahead the vessel is capable of an astern speed of from 28 percent to 35 percent of her ahead speed. The British Admiralty has installed these rudders in a large number of auxiliary craft and, from data taken, it has been reported that the speed of each vessel fitted has been increased from 3 percent to 6 percent over that of the standard type of rudder.

The Motorship Alca

An example of this new form of rudder, as installed on the motorship *Alca,* may be of interest, especially when it was considered doubtful that the installation would be a success due to the low powered land type propelling unit installed. The vessel, however, has now been in continual service for over one year between the Bay of Biscay and Mediterranean ports. The *Alca* is a steel vessel of 500 tons displacement and 300 tons deadweight carrying capacity engaged in carrying coal and general cargo. Her dimensions are as follows:

Length	140 feet
Beam	22 feet 3 inches
Depth, molded	10 feet
Load draft	8 feet 3 inches

Engine, Sulzer Diesel land type (non-reversing), 150 brake horsepower direct connected to a propeller 4 feet in diameter.

The *Alca* was originally built as a sailing vessel; she has now been rerigged and fitted with cargo booms. To install the Kitchen rudder the original rudder post was removed by cutting through at the top and bottom of the propeller aperture, an extension to the stern foot to take the bottom pintle was added and a strong gudgeon was riveted to the hull to receive the rudder stock. The rudder blades are of mild steel plate ½ inch thick, the inside dimensions of the rudder being 64 inches by 58 inches, the major axis being horizontal. The maneuvering and reverse control for operating the rudders is installed in the pilot house. The ordinary type of hand steering wheel is used, this being independent from the maneuvering control. The remote control as installed on the *Alca* is operated manually, power gear not being necessary owing to the low engine brake horsepower and small diameter propeller. The motion from this control is conveyed to the rudder head operating gear by means of steel chains over guide sheaves and rollers; it is this gear which regulates the opening and closing of the rudder blades, thereby regulating the ahead and astern speed of the ship.

During her trials the *Alca* attained a sea speed of 6¼ knots. The following results of maneuvering are interesting:

From full ahead to dead stop, time taken 34 seconds and distance traveled 200 feet.
Diameter of turning circle, rudder 25 degrees hard over at full speed ahead, 140 feet.
Time taken to spin on own axis, as if on a pivot, without progression through half circle, 1 minute 25 seconds.

The owners of the *Alca* report that during the first year of uninterrupted service the rudder control is most efficient and practically instantaneous in effect.

New Danish Motor Lightship

By H. C. Snethlage

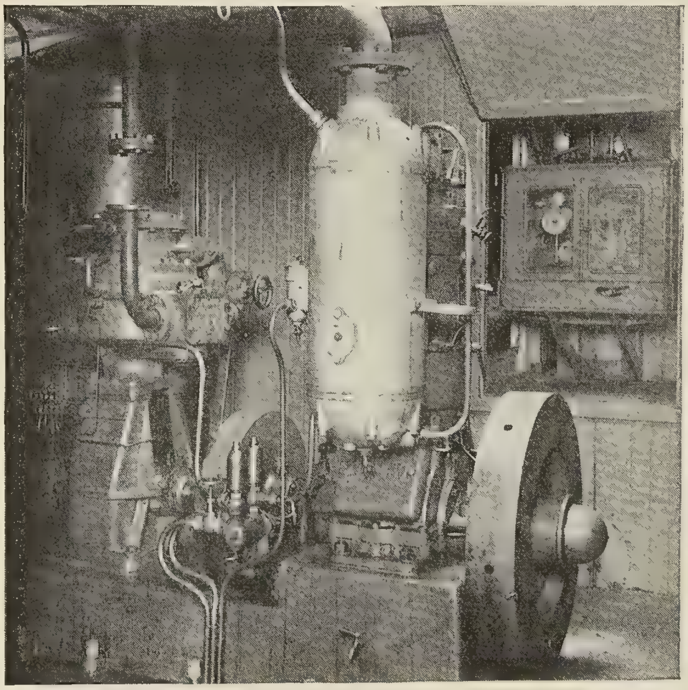
In view of Secretary Hoover's emphatic report that sixteen new lightships are urgently needed, as mentioned in the January issue of this magazine, it will prove interesting to American readers to see photographs of an up-to-date Danish lightship provided with crude oil engines.

This installation is another proof of the absolute reliability of the crude oil engine for marine purposes. The seas around Denmark are very stormy. Ask any captain who has passed

Motor Lightship Halskov-Rev

the "Skaw" on a stormy winter night. And since the power plant on a lightship is apt to be used on just such a stormy night, it is evident that no chances can be taken with machinery that is not absolutely reliable.

Due to the success of large motor merchant ships in Denmark, the Danish lighthouse service decided to investigate if that type of motive power could not be used to advantage on their ships. An 80 horsepower Volund motor manufactured by the Volund Company of Copenhagen was first tried



Motor Compressor for Lightship Fog Horn

out on one of the smaller lighthouse vessels, and since this engine proved satisfactory in every way, all Danish lightships are now provided with that type of motor.

The main propelling machinery consists of a 135 horsepower crude oil motor. It is of the two-cycle, valveless, trunk piston type with a hot bulb, used for ignition, placed on top of the cylinder. An interesting feature of this installation is that no water injection is used. The weight of the machinery is only about 180 pounds per horsepower, which compared with 400 pounds for a steam installation gives a saving of 12 tons in displacement for the motorship.

Not only is the main propelling machinery motor driven but the fog horn is handled by an air compressor direct connected to a 27 horsepower one-cylinder Volund motor as shown in Fig. 2.

This lightship is stationed off the west coast of Jutland, not far from the spot where the greatest naval battle in history was fought. This coast line is not unlike our Atlantic coast line in that there are plenty of opportunities for ships to go on the rocks. The Danes, however, are taking no chances. Equipment as good as can be had is placed in this service. Is there any reason why this country, with resources many times greater than Denmark's, should stand back and let the lives of thousands of people depend on out-of-date lightships, some of which are over 50 years old?

Now is the time when Congress should take action. We have shipyards here second to none. Why should these yards be allowed to be temporarily idle, when new construction of such vital importance to American shipping could easily be done now, thus keeping the highly trained shipyard organizations intact?

We hope that Congress will see this point and that in the near future, lightships of the most modern type will be under construction in our shipyards.

Fire Tube Superheaters Save Fuel on Railroad Tugs

Indicated Horsepower Increased from 5 to 27 Percent—Fuel Consumption Reduced from 15 to 17 Percent—Maintenance Costs Negligible

Fuel economy, increased capacity, greater operating efficiency and freedom from maintenance troubles—advantages claimed for the fire tube superheater—have been convincingly established by the successful operation of high degree superheat on the sea-going tugs *Wyoming, Perth Amboy* and *Lehigh,* formerly owned by the Lehigh Valley Railroad and now owned and operated by the Bee Line Transportation Company.

The *Wyoming,* a vessel of 398 gross tons, 152 feet long, 27 feet 3 inches beam and 16 feet draft, with a towing capacity of 5,000 tons, was the first American boat operating in American waters to be equipped with fire tube superheaters. The *Wyoming* was fitted with superheaters in June, 1915, by The Superheater Company (then the Locomotive Superheater Company), New York.

Economies Effected

In November, 1916, after a series of operating tests on the *Wyoming* had shown a coal saving of 15⅝ percent and an increase in capacity of from 865 indicated horsepower on saturated steam, to 908 indicated horsepower on superheated steam, a second tug, the *Perth Amboy,* was equipped with the same type of superheaters.

Similar and even more careful tests were run on the *Perth Amboy,* and the results compared with saturated steam operation under identical conditions. Superheated, the *Perth Amboy* developed 887 indicated horsepower against 775 indicated horsepower on saturated steam. A fuel saving of 15 percent was shown.

The *Lehigh,* the third of the fleet, was equipped with the same kind of fire tube superheaters in March, 1917. The *Lehigh,* after superheating, developed 803 indicated horsepower against 633 indicated horsepower on saturated steam. On the *Lehigh,* the fuel saving proved to be 17 percent.

Maintenance Costs Practically Nil

Any doubts as to the practicability of the fire tube superheaters for use on this type of vessel are removed by the performance and maintenance records of these superheater-equipped tugs. Over considerable periods of continuous operation, six years in the case of the *Wyoming,* five years on the *Perth Amboy,* and upwards of four years on the *Lehigh,* maintenance costs on the superheater equipment of these vessels have been practically nil.

No trouble has been experienced through the use of cylinder lubrication. The *Perth Amboy* has run two and one-half years on one set of rings in the high pressure cylinder with 180 degrees of superheat. All three ships average 60 to 70 hours on one quart of oil in the forced feed lubricator. Recent examination of the rods, rings and cylinder liners of these superheated tugs showed them to be in excellent condition.

Tug Wyoming, on Which the Installation of Fire Tube Superheaters Cut Down the Fuel Consumption Over 15 Percent

Comparative performances of the Lehigh tugs on saturated and on superheated steam are shown in Table I.

Description of the Superheaters

The fire tube superheater, as installed in the Lehigh Valley Railroad tugs, consists of three pairs of collector castings or headers, located at the uptake end of the boiler, each pair of headers being connected to a group or nest of superheater unit pipes, which run in and out of the boiler smoke tubes. Of each pair of headers one takes the saturated steam as it comes from the boiler and transfers it to the superheater units; the other receives the superheated steam after it has passed through the units on its way to the engines.

In this superheater there is a total of 80 units, arranged in three groups, corresponding to the number of pairs of headers. These groups, each made up of a saturated and a superheated header, with a system of units, are independent in their action, being separated from each other by valves.

High Degree Superheat Successful

The degree of superheat obtained can be governed by a mixing pipe, which keeps the superheated steam at any desired temperature by admitting the proper amount of saturated steam to the main steam pipe. The average steam temperature obtained with this superheater is about 565 degrees, which, with a steam pressure of 180 pounds, is equivalent to 185 degrees of superheat. A maximum steam temperature of 620 degrees, corresponding to 240 degrees of superheat, has been successfully maintained.

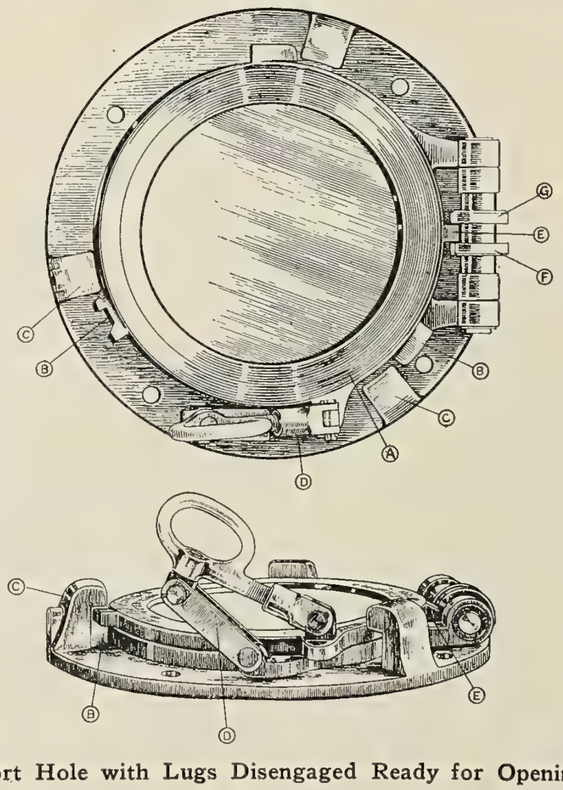
High degree superheat and fire tube superheaters have been employed extensively in European marine service for many years. It is interesting to note that the first American shipowner to equip a vessel with fire tube superheaters was an American railroad on which high temperature superheat and superheaters had come to be regarded as essential to efficient, economical locomotive operation.

Automatic Locking Safety Port Hole

THE "Smithson" safety air ports with which the *Olympic* is equipped are now being manufactured in the United States by the Mercantile Specialties Company, 11 Broadway, New York. Rapidity of closing is a special advantage claimed for the port and this is accomplished without the use of a spanner or key. The port is provided with an automatic lock which is arranged so that the port can be left under the control of the passenger when desirable or locked by simply removing a special key.

The mechanism of the port consists of a rotating ring *A* by means of which the port is fastened. This ring carries a series of wedge blocks *B* which engage under lugs *C* on the base frame, when the port is closed. The pressure of the ring on its rubber seat is uniform and eliminates the possibility of cracked glass and strains on the porthole frame. The ring is rotated by means of toggle *D*.

In opening the port, a toggle handle is raised until the ring has rotated sufficiently to allow the stop *E* to pass through the slot in collar *F* and bring up against the collar *G* which prevents further movement and allows the port to open. To close the port, the handle is simply moved down,



Port Hole with Lugs Disengaged Ready for Opening

when the stop *E* passes through the slot in collar *F*, allowing the rotating ring to move and engage the wedge blocks under the lugs.

In England the device has been approved by the Board of Trade for all classes of ships.

Canvas, Bunting and Felt for Shipbuilding Purposes

By Horace Holden Thayer*

Continuation of a series of articles containing information regarding shipbuilding materials and their uses that is not readily obtainable from shipbuilding handbooks and other generally available sources. The articles are not intended to be a complete exposition of the subject but will be found to contain items of value to the various classes of workers in this field who have to deal with these materials from the materials point of view.

THE canvas of principal value for shipbuilding purposes is cotton duck and the heavier weights of cotton duck are always sold by number, hence the material is known to the trade as Number Canvas.

Number Canvas

It is customary to call for cotton duck when specifying canvas for sails and frequently some well known and thoroughly tried out brand is designated, but it is not so well understood that practically all of the canvas used about a ship should be of this material, including deck coverings and the less important covers for items of equipment exposed to the weather.

The nature of Number Canvas and the usual requirements which govern the production of this material are embodied in the Navy Department detail specifications for cotton canvas, and can probably be best and most concisely stated by the following excerpts from these specifications. The warp threads run lengthwise of the piece and the filling threads run at right angles to the warp threads.

Quality.—The canvas shall be made of cotton of a grade not inferior to middling cotton thoroughly cleaned, with yarn evenly spun. The thread shall be twisted multiple ply, the number of ply to depend upon the weight and number of the canvas. The fabric shall be properly woven and as free from lumps, knots and imperfections of manufacture as the best commercial grades of canvas.

Width and Length.—The canvas shall be uniformly woven with even and straight selvages to the full width specified, an excess width of ¼ inch being allowed. The width of any bolt shall be uniform throughout its entire length. Two-thirds of any delivery shall have a length of at least 90 yards per bolt. Shorter lengths, ranging from 45 yards up, will be acceptable, but not more than one-third of any delivery shall consist of short-length bolts.

Tests.—The strength of the material shall be determined as follows: (a) Test pieces will be prepared by cutting samples 8 inches long by 1¼ inches wide and then pulling out threads from both sides of the narrow section of warp test pieces until three threads remain on each side of a standard width of 1 inch. All filling test pieces will have threads pulled out until a standard width of 1 inch is reached.

(b) Five test pieces from the warp and a like number from the filling taken within the selvage will be dried for one hour at a temperature of 150 degrees F.

(c) The test pieces immediately upon removal from the drying oven will be placed in the jaws of a testing machine with jaws 3 inches apart and pulled to rupture at a rate of 20 inches per minute.

Strength, Etc.—(a) The strength of no one of the five test pieces cut from either the warp or the filling of the same bolt shall be less than the average strength of the five by a greater amount than 10 percent of that average.

(b) The strength and other physical characteristics of the material shall be as follows.

A table follows which gives the standard weights of the canvas per linear yard under normal atmospheric conditions, from which a variation of 2 percent calculated from the weight of an entire bolt is permitted, gives distances of the customary blue warp thread from the edge, ranging from 1 inch on the No. 10 canvas to 1¾ inches on the No. 1 canvas, and gives the minimum strengths allowable. These strengths, in pounds, are:

	Warp	Filling
No. 1	160	200
No. 2	150	190
No. 3	145	180
No. 4	140	170
No. 5	135	150
No. 6	125	140
No. 7	120	115
No. 8	105	105
No. 9	100	105
No. 10	95	95

Number Canvas is made hard, medium and soft in all numbers to 6 inclusive and all lighter canvas is hard. The hard is the tightest weave, most waterproof and best for deck covering and covers generally. The medium is best for sails as it is not so stiff and difficult to handle when wet. The soft is not needed for shipbuilding purposes.

The numbers range from 12/0, which is extremely thick and heavy, to 1/0 or 0, and thence on down to No. 12, which is the lightest and has a two thread warp and a two thread filling. The numbers most met with in shipbuilding are 0 to 6, although large sails are sometimes made as heavy as 2/0. No. 0 is about .055 inch thick and one yard 22 inches wide weighs 19 ounces. No. 6 is about .043 inch thick and one yard 22 inches wide weighs 13 ounces. It will be noted from this that in the 22-inch width the weight varies one ounce with each number. In order to compare the weight of Number Canvas with that of any canvas which is sold by weight it is only necessary to divide the even ounces of the Number Canvas which apply to the 22-inch width by 22 and to multiply by the width in inches which forms the basis for the ounces, or the weight per yard, of the other canvas. The table given below, which shows the weights of Number Canvas for the standard widths of Army Duck and Ounce Canvas, will be found of convenience in this connection.

Weight Per Linear Yard in Ounces

Width in Inches—	22	28.5	29
No. 0	19		
No. 1	18		
No. 2	17		
No. 3	16		
No. 4	15		
No. 5	14		
No. 6	13		
No. 7	12	15.5	15.8
No. 8	11	14.2	14.5
No. 9	10	13.0	13.2
No. 10	9	11.7	11.9
No. 11	8	10.4	10.5
No. 12	7	9.1	9.2

Standard widths for sail duck are 22 inches to conform to the practice in this country and 24 inches to conform to the practice in England. These widths are often used for deck covering and in other places where narrow strips are desirable. Number Canvas from numbers 1 to 12 can be obtained in widths from 6 inches to 144 inches.

*Member of the firm of Rossell & Thayer, Naval Architects and Marine Engineers, Philadelphia, Pa.

Army Duck

Army Duck is of the same weave as Number Canvas, both the warp and the filling threads being twisted. These threads are lighter than those of the Number Canvas and the material is therefore of a tighter weave and even more waterproof than the Number Canvas. It was designed particularly for the making of tents.

Army Duck is graded by weight, which tends to confuse it with Ounce Canvas. The standard width is 28½ inches and the weights per linear yard at that width are 7, 8, 9, 10, 12 and 15 ounces. It can also be obtained in a 37-inch width weighing 10.38 ounces per linear yard and in a 40-inch width weighing 11 ounces, and greater widths are made to order.

The writer understands that the Navy canvas which they call Ravens is this Army Duck. Ravens is incorporated with duck in the Navy detail specifications for cotton canvas and the requirements for it are identical with those before quoted under the heading of Number Canvas except that the bolts are not required to be over 65 yards in length. The width is 28½ inches and the minimum strengths allowable, in pounds, are:

	Wrap	Filling
8-ounce	80	55
10-ounce	100	65
12-ounce	105	95
15-ounce	125	115

Ounce Canvas

Ounce canvas, which derives its name from the fact that it is graded by weight, is of a different weave from Number Canvas. The warp consists of two threads which lie side by side untwisted, and the filling is either a single or a multiple thread, the latter being twisted. The two kinds go by the names of single filled or double filled canvas, and both unfortunately often also go by the name of duck. The double filled canvas of any weight is of tighter weave and is stronger and more waterproof than the single filled canvas, but it is not the equal in strength or watertightness of true cotton duck.

The weights are based upon a standard width of 29 inches and no other width can be readily obtained. They are 7, 8, 9, 10, 12 and 15 ounces per linear yard, and the single filled canvas can also be obtained in a 6-ounce weight.

The double filled canvas is of value for cushion covers and similar service. The single filled canvas for shipbuilding purposes can be considered only as a cheap substitute for the double filled canvas.

Enameling Duck

Enameling Duck is the trade name for canvas that is made like the double filled Ounce Canvas, of a standard weight of 8 ounces per linear yard 38 inches wide, or two yards to the pound. It can also be obtained in greater widths, all of the same thickness and of correspondingly greater weights. These widths and their weights are as follows:

38-inch	8.	ounces
46½-inch	9.8	"
51½-inch	10.8	"
57-inch	12.	"
61-inch	12.8	"
72-inch	15.2	"

This canvas is of value for pipe and boiler coverings, the 38-inch width being used mainly for the former and the greater widths for the latter.

A single filled canvas of this nature may be obtained but as with the regular run of Ounce Canvas it is only a cheap substitute for the double filled canvas.

Hose Duck

Hose Duck is of the same construction as Number Canvas, with twisted warp and filling threads, but it is of a looser weave and softer. It comes in a standard width of 40 inches and in weights of 10, 12, 14, 16, 18, 20 and 22 ounces per linear yard. It can be obtained in greater widths to order.

As its name implies, it is used in the manufacture of hose. It is also of value for pipe coverings.

Other Canvas, Etc.

There are other special types of canvas, but they seldom or never find their way into the shipbuilding field; and there are other cloths which may be substituted in some cases for canvas. One of the latter which it may be of value to refer to is a cloth made of flax, imported from Belgium, which when waterproofed makes an excellent material for the covers and side cloths of deck lighters and similar service, being very durable and pliable as well as of a tight weave.

Waterproofing Canvas

Canvas is waterproofed mainly by concerns who make that their special business and who treat it with some solution which is their particular property. Suitable compounds of this nature can be obtained by shipbuilders and sailmakers who may desire to do their own waterproofing, but the general practice except for small hurry-up jobs is to leave this work to specialists in this line.

Canvas covers are sometimes specified to be paraffine coated. Although this tends to preserve the canvas it is poor practice from a waterproofing standpoint because it flakes off with the moving about of the covers and with cold and does not stand up under any considerable heat.

Uses for Canvas

Some of the more important uses for canvas on shipboard as well as a suitable weight of canvas for the particular service are listed in the following table. Where a number alone is given it is the number of Number Canvas. The sails of large sailing vessels as listed are those of the barkentine illustrated by the accompanying plan, and their locations may be readily determined by reference to the corresponding numbers of canvas on this plan. These weights will form a fair guide for the weights of sails in similar locations generally.

List of Sails for a Barkentine

	Number or Weight of Canvas
Sails of Large Sailing Vessels	
Fore staysail	1
Fore topmast staysail	1
Inner jib	2
Outer jib	3
Fore sail	0
Lower top sail	0
Upper top sail	1
Top gallant sails (2)	3
Royal	4
Main staysail	2

Switchboard	8-ounce Army Duck
Miscellaneous portable covers	12-ounce Double Filled
Miscellaneous	
Bags	4
Cots	7
Hammocks	1
Pipe and boiler covering	8-ounce (for 38-inch width) Enamelling Duck
Sea anchors	6 or heavier
Swimming tanks	0
Upholstery	8-ounce Double Filled
Wind sails	4
Wood watertight bulkheads	6

Wool Bunting

The only bunting of real value in the marine field is Wool Bunting and its nature and the requirements that it should live up to may be best stated by quoting from the Navy Department detail specifications for this material.

Quality.—Wool bunting shall be made entirely of the best quality of wool, well woven, finished, of good workmanship, and free from all defects and blemishes which may affect the appearance or serviceability of the fabric.

Construction.—The yarns shall be well and evenly spun; both warp and filling shall each contain not less than 34 threads to the inch; the warp shall be two-ply and the filling one-ply, properly twisted.

Width and Weight.—The bunting shall be fully 18 inches in width. The weight shall be not less than 5¼ pounds avoirdupois per piece or bolt of 40 yards.

Strength.—The average strength of the material shall be not less than 25 pounds per inch of width of warp and not less than 18 pounds per inch of width of filling, based on test pieces prepared and tested as follows:

(a) The test pieces will be prepared by cutting samples 8 inches long by 1¼ inches wide and then pulling out threads from both sides of the narrow section until the standard width of 1 inch is reached.

(b) Ten test pieces, 5 from the warp and 5 from the filling taken from various parts of the fabric within the selvage, will be dried for 1 hour at a temperature of 150 degrees F.

(c) Immediately upon removal from the drying oven, the test pieces will be placed in the jaws of a testing machine with jaws 3 inches apart, and pulled to rupture at the rate of 20 inches per minute.

Comparison with Standard Sample.—Deliveries shall be equal or superior in quality, finish and all other respects to the standard samples, portions of which may be obtained from the navy yard at which delivery is to be made; color shades of deliveries shall conform to the standard sample of bunting on hand at the navy yard, New York, and tests of colors as outlined in paragraph 7 below shall be made upon samples taken from deliveries and from standard samples on hand at the navy yard, New York.

Tests of Colors.—Colors shall be fast and stable when exposed to light or the action of fresh or salt water. When samples taken from deliveries and from the standard sample on hand at the navy yard, New York, are subjected to the same tests, the results of the tests upon the delivery shall be at least equal to the results obtained upon the standard sample in immersion in fresh water, salt water, exposed to the rays of a quartz-burner mercury-vapor lamp, and exposure to the weather for 10 days, of which not less than 30 hours shall be bright sunlight.

Packing.—Each bolt of bunting shall contain at least 40 yards of bunting, shall be neatly and evenly rolled upon a wooden roller, and wrapped in paper. The wrapping shall be closed at each end by a paper label of the color of the bunting, and shall be plainly marked with the quantity in the bolt.

The only important use for wool bunting is in the making of flags of all kinds. It is sometimes used for decorative purposes.

Cotton Bunting

Cotton Bunting is a poor material and the colors are not fast.

The fact that the Navy Department has prepared detail specifications for Cotton Bunting along the lines of their specifications for Wool Bunting might lead to the conclusion that the former can be used for flags with satisfactory results. This is, however, not the case. The specifications were prepared in 1917 as a war emergency measure on account of the difficulty in obtaining Wool Bunting in sufficient quantities.

Sheathing Felt

The sheathing felt used for various purposes about a vessel, as a backing for wood or metal sheathing on a wood hull, or for canvas on joiner decks, between the layers of double wood bulkheads, as a calking material, etc., is a product which is imported from Ireland. It is made of flax or jute, cow hair and pine tar. It comes in sheets about 1/16-inch thick and 32 inches by 36 inches and 32 inches by 40 inches in size, which are packed in crates containing 250 sheets each.

The Navy Department detail specifications for tarred sheathing felt state that it shall be made from jute or flax saturated with approved resinous or tarry material, that it shall be delivered in sheets about 32 by 40 inches, and that it shall weigh not less than 2 nor more than 3 ounces per square foot.

Imitations of this felt are produced by one or more of the paper mills in this country, but such of this product as has come to the attention of the writer is very inferior and undesirable for shipbuilding purposes.

A Few Suggestions

Specify Number Canvas, or its equivalent in the lighter weights, for all service where strength and waterproof qualities are important.

Use a well tried make or have the material tested.

In dealing with canvas that is named by weight be sure of the width to which the stated weight has reference.

Use narrow widths, 14 inches to 20 inches, for sails of yachts and other small vessels as these are easier to handle and will lie better.

Canvas should be waterproofed when it is to be used for the top tarpaulin on weather deck cargo hatches. These hatches should preferably have three tarpaulins on them, all of the same weight.

Waterproofed canvas should be used for deck cargo covers.

Canvas swimming tanks should be double, the outer canvas being waterproofed. The inner canvas should also be waterproofed were it not for the oily nature of the coating used.

Canvas for dynamo covers should be waterproofed.

Canvas covers are usually not required for deck machinery such as the windlass, winches and capstans.

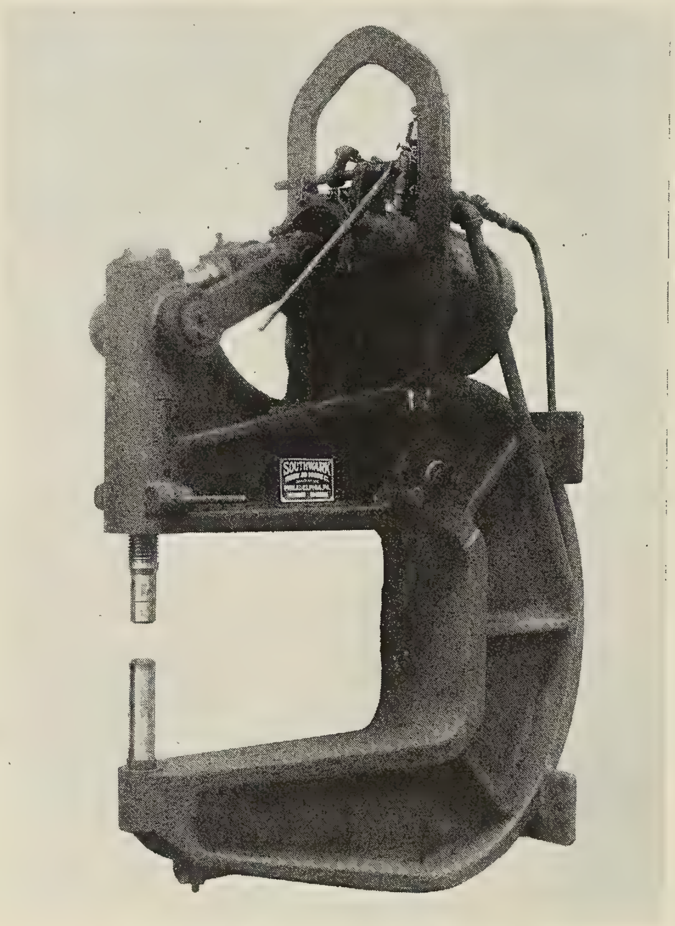
The old practice of laying felt on joiner decks underneath the canvas is not a good practice and involves unnecessary expense. Owners and shipbuilders are coming more and more to a realization of this. The argument in favor of the felt is that the tongue and groove construction of the decking causes the boards to stand up at the edges, thereby bringing about the rapid wear of the canvas along these joints when felt is not used and also making an uneven appearance. This difficulty can be overcome where necessary by going over the edges with a plane.

The objections to the felt are the cost and weight of the felt and the fact that when felt is used the canvas is more apt to be torn by boards or other heavy objects dropped on it. The felt is also said by some to rot the canvas.

Where the wood decking is given a thick coat of white lead and linseed oil paint and the canvas is laid while this is wet, and immediately given a heavy coat of linseed oil, and then two or three coats of white lead paint, according to the location, the results will be as good as, if not better than, with felt between the canvas and the wood.

Driving Rivets With Toggle Type Pneumatic Riveters

FOR portable service pneumatic toggle type compression riveters have been found well adapted, while hydraulic riveters are generally used in stationary work where machines of deep reach are needed. The following explanation is given of the action of the toggle arrangements on pneumatic compression yoke riveters built by the Southwark Foundry and Machine Company, Philadelphia, Pa., which specially adapts them to portable service. Riveters are made by this company in sizes from 15 tons up to those developing 150 tons on the die and having a reach of 23 feet.



Pneumatic Toggle Type Riveter

The toggle mechanism is designed to act rapidly until the die reaches the point of the rivet when it gradually decreases in speed and at the same time increases the pressure exerted on the rivet. The die travel is practically uniform towards the last of the operation and thus ensures driving tight rivets, drawing the plates together and following up the shrinkage of the rivet with full pressure until it is set. The die should be adjusted for any run of work.

All portable machines are provided with means for suspension and those above 36-inch reach with feet for mounting when used in stationary service.

The Most Interesting Job in the Yard

In comparing one job with another in a shipyard there is always some feature of special interest not only to the man who holds the job but also to the other workers in the yard. In recent issues we have published the views of machinists, engineers and engine builders. This month a draftsman tells why he considers his job the most interesting one in the yard. How does your job compare with these? Tell us about it.

NULLI SECUNDUS has chosen a doubtful nom-de-plume, at least I consider that the interest factor in his job is a long way second to that in mine. I am a draftsman. That statement in itself is almost enough without elaboration but the justification for my claim must be set down, so I propose to take one order I received from my chief to prove it.

I was working in a large naval establishment when the order came to "get out the torpedo arrangements." I had my complete order in those few words, but what a vista of interest it unveiled!

First I had to consider the general arrangement. There never had been a ship with eighteen torpedo tubes before. The tubes were new, the torpedo was new, the general idea was new and the whole job was fresh. I had to arrange the position of the tubes, how to get them into the ship, how to secure them and how to protect them from gunfire. Then to get the torpedoes on board from a wharf or from the water, to devise ways and means to transport them along the deck, strike them down to the 'tween deck space, to transport them there to stowage positions, to each and every tube, to workshops and assembly room and to turn them end for end in a limited space. Then came the arrangement of magazines to stow the war heads and dummies, to arrange workshops with benches and machines, to work out details of stowage brackets, transporting trolley, special hatchways, pulleys, derricks and winches and a host of accessories.

Just take one item as a sample of interesting work—the idea for protecting the tubes from gunfire. Large armored doors had to be arranged to hinge outboard and to be geared to work from inside. Each door weighed about 2½ tons and there were two at each set of tubes. The gearing had to be strong enough to open the doors against a list of several degrees and yet work easily so that one or two men could operate them. I saw that if a wave hit the forward door it might destroy the gearing so I had to devise a friction clutch between the hinge and the gear which would hold enough to open and close the door and stand a sufficient pressure to insure that the doors were reasonably watertight when they were shut but which would slip if a blow were applied before the worm of the gear would strip.

Here was interest indeed! I had to resuscitate my knowledge of worm gears and ball bearings, to polish up my calculus and the theory of the screw with friction and to sharpen my wits as well as my pencil. By the time the design was finished there was little of interest left to spare for Nulli Secundus. His work was reduced to reading the drawing. (You can see those doors and friction clutches in the lower left hand corner of Fig. 19, page 214, of your March, 1921, number, Mr. Editor.)

Then again there was the transporting job. To get a ton and three-quarters of torpedo down a hatchway, not more than three-fifths of the length of the torpedo long, into a 'tween deck space only seven feet six high required a nicety of placement of tackles hard to equal. Then to work out the tracks so that the long body could be moved from end to end of the ship and turned about and switched to each tube and stowage point was another phase. This involved considerable scheming and the design of a lifting block which would work in a headroom 6 inches less than had previously been designed for and that at an increase of lifting power.

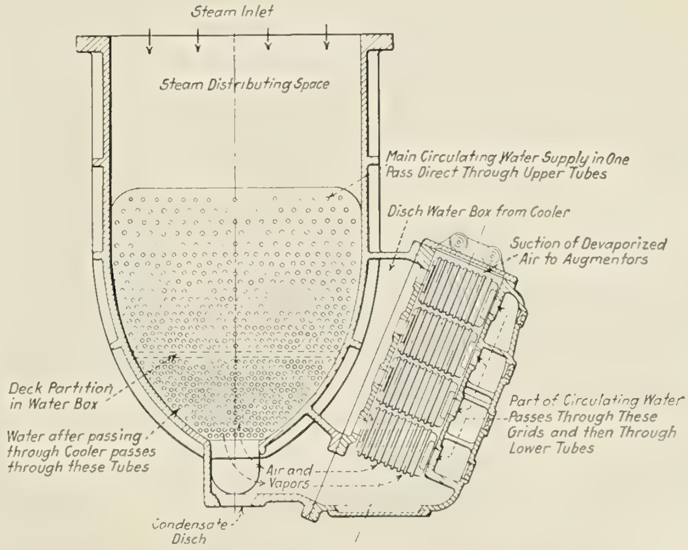
That one order led me to prepare 26 arrangement and detail drawings in the course of 12 months and I can say that there was not a melancholy moment in the whole time. Considering that a large vessel bristles, from keel to truck, with such tantalizing problems, can it be wondered that I claim for the draftsman the premier place as the holder of the most interesting job in the shipyard?

Pulman qui meruit ferat.

New Brighton, N. Y. I. C. G. Cooper.

Waste Tubes Eliminated in New Surface Condenser

SURFACE condenser troubles are in general of two kinds—corrosion, causing tube leakage, and the accumulation of slime and scale fouling the tube walls, both due to unsuitable boiler feed water. To overcome these difficulties, the Ingersoll-Rand Company, New York, has developed an improved type of condenser in which waste tubes are eliminated, a uniformly high condensate temperature is maintained, counter-current air cooling provided and corrosion and fouling reduced to a minimum.



Cross Section Through Main Condenser and Cooler

Waste tube elimination is secured by arranging the tubes in "stages," by correct shell shape and by the use of a separate devaporizer-cooler. The tubes spaced on wide centers in the top of the shell are brought closer together in each lower bank or stage. The shell itself is gradually narrowed from the widest point at the top to that of a nozzle running the length of the shell under the last row of tubes. This construction gives a sufficiently high steam velocity to sweep condensate and air films from the tubes, which action compensates for the decreased volume of the steam as it is condensed in its passage down over the tubes. The residual air and steam from the last row of tubes is drawn up into the cooler which is mounted on the side of the shell proper and fitted with cast iron cooling grids whose

surfaces are adapted to devaporize and cool the air before it passes to the vacuum pump.

The devaporizing and cooling of the air is carried on independently in the cooler through which the flow is upward to the vacuum pump or steam jets. It is thus possible to cool the air without a corresponding lowering of the condensate temperature.

A single-pass arrangement in the I-R condenser makes possible high water velocities without excessive friction. The tubes are kept clear of slime and scale by this means which tends to reduce the temperature at the inner tube walls.

LETTERS TO THE EDITOR

Wear of the Teeth of Marine Turbine Reduction Gears

The wear of the teeth of marine turbine reduction gears is not being eradicated with material success, and it is unfortunate that such important parts of the propelling machinery of steamships should require exquisite workmanship and fitting and so much attention to oil and oiling. These features are especially out of place on such a coarse and flexible structure as a ship.

While no part of a marine turbine can stand inaccurate fitting and alinement such as are somewhat possible with reciprocating engines, designers are getting themselves more deeply into difficulty and there will be no outlet, if refinement is the attempted remedy. Any mechanism should have means of rendering slight inaccuracies harmless, but that principle cannot be applied to present designs of reduction gears.

The precision required in the case of double, and but slightly less with single reduction gears, should by some change become unnecessary. Considering the single turbine double reduction gear, the small pinion lies between two large gears and the teeth must fit them both exactly. That presents great difficulty, because the pinion and gears are each made in two parts with helical teeth inclined in opposite directions. These teeth must be located with the utmost nicety, and here more undesirable precision is required.

Still further, the two gear shafts each have a double pinion with oppositely inclined helical teeth, and the secondary gear must fit these two pinions. If one half pinion tries to accommodate itself to its gear, it tries to pull all other gears out of place. The whole assemblage is locked and there is no opportunity for accommodation to distortion or temperature changes.

Moreover, the longitudinal immovability of the system violates an important requirement for good distribution of lubricant and uniform wear. When Professor Sweet designed the Straight Line Engine he made the crank pin and shaft bearings longer than the boxes in order to permit free longitudinal movement of the shaft so that it could distribute the oil and wear uniformly. This is also done on direct current electric machines in order to wear commutators uniformly, and unless it is done with turbine gears there will never be any certainty of success, especially with double reduction gears. In the second reduction the halves of each pinion are some distance apart with a bearing between and, if the bearing heats and expands, the pressure on the teeth due to wedging action must be tremendous. This pressure not only occurs at this point but is transmitted to the primary pinion and the latter must encounter almost impossible service. These troubles have been somewhat reduced by having the secondary pinions on sleeves driven by interior shafts clutched to them at the aft ends. This is a step toward the accommodation for which I am pleading.

The requirements here pointed out, of course, can be met only by the use of teeth parallel to the axes of the shafts, and I venture to predict complete success with such gears on the first trial, especially if end play of shafts is allowed, and that they will ultimately be used. Pinions can be single and the necessity for intermediate pinion and gear bearings disappears, as well as sleeve shafts and clutches.

When De Laval turbines first appeared they had gears with helical teeth, and nobody has ventured to abandon them. Designers appear to assume that such gears are necessary, but as long as they are used there will be trouble.

Another cause of difficulty comes from using steel on steel. If anything is well established it is that steel on steel is a bad rubbing combination. Steel is selected on account of its strength, but cast iron would be much better, and, except the pinions, could probably be made of sufficient strength. Cast iron is the best of all rubbing materials because it has small cavities which hold oil. Steel rubbing on cast iron does well, and it would probably work well to have steel pinions working on flanged cast iron toothed rings bolted to the gear centers. Strong air furnace castings should be used.

Boston, Mass. F. W. Dean.

Should Direct or Alternating Current Be Used for the Lighting Set?

The almost universal use of direct current for lighting purposes on board ship is no more conclusive evidence of its superiority to alternating current than the fact that we now walk, whereas in a few decades we shall probably fly with equal ease, is an argument that walking is the better method.

Leaving out the main advantage of alternating current, the ease of transmission and distribution, because on a ship this is not paramount although very real on a large boat, and without enumerating the special advantages of alternating current apparatus and the simple alternating induction motor, it cannot be gainsaid that this same alternating current motor is the most widely used piece of apparatus in the world today. This would be no argument, if there were any other equal method put forth, but there is no direct current motor that has equaled its ruggedness, simplicity and general usefulness. It has no flash-over troubles, no commutator to take care of, and when voltage is applied it is bound to go; it can be reversed easily and definitely; speed changes can be made by using field combinations and the more improved types of induction motor will give all the speed regulation necessary for any service.

Witness the recent use of this motor in crane service, where the direct current motor was thought impregnable. Bells, signals, enunciators, lights, motors and accessories can be operated more efficiently from alternating current than from direct current, and such apparatus as requires storage batteries, such as telephones, telemotors and exciters for the alternating current regulators, can be supplied from a storage battery which is necessary on board a ship whether alternating current or direct current is the power supplied.

Alternating current wiring is just as simple as direct current wiring at the same voltage and the underwriters, or Lloyds, or the American Bureau of Shipping make no difference in the wiring requirements, except that direct current switching apparatus, because of the great danger of flash-over at heavy current and low voltage, has to be especially safeguarded whereas the flash-over from an alternating current circuit, which is non-inductive as is a lighting circuit, is practically nil. This latter feature of no flash-over is probably a safety feature of a thousand times more magnitude than the fact that direct current on the same voltage does not give as great a tingle or shock to the operator as alternating current.

Alternating current has been the ultimate winner in every field in which it has competed and I am very glad to see the subject raised in shipbuilding circles.

Newark, N. J. Young American.

Questions and Answers for Marine Engineers

Inquiries of General Interest Regarding Marine Engineering and Shipbuilding Will Be Answered in This Department

Conducted by James L. Bates

This department is maintained for the service of practical marine engineers, draftsmen and shipbuilders. All inquiries should bear the name and address of the writer. Anonymous communications will not be considered. The identity of the writer, however, will not be disclosed unless the editor is given permission to do so.

Size of Piston Ring—Arrangement of Buckets on Side Wheels—Lining Up a Beam Engine

Q. (1142).—(1) How much larger should a piston ring be than the steam cylinder to which it is to be cut and fitted? How much should be cut out of the eccentric turned rings, and give the thickness of the thinnest and thickest places? While I have in mind a steam cylinder of 6⅛ inches bore, I am anxious for a rule or formula that can be used for other rings.

(2) With a beam engine driving two side wheels, what effect will the loss of a few buckets have on the speed of the vessel, the steam pressure and throttle opening remaining the same as before? Should the same bucket area be put on all arms, or will there be anything gained in speed and fuel, if more buckets are added on the wheels, that they may be in the water when the maximum pressure is on the shaft? Explain how I may better balance my engine and save fuel, making same speed.

(3) How would you line up a beam engine?

A. (1142).—(1) The following quoted from "Mechanical Engineers' Pocket Book," Kent, edition 1916, pages 1023 and 1024, is believed to cover your question:

"Diameter of Piston Packing-rings.—These are generally turned, before they are cut, about ¼ inch diameter larger than the cylinder, for cylinders up to 20 inches diameter, and then enough is cut out of the rings to spring them to the diameter of the cylinder. For larger cylinders the rings are turned proportionately larger. Seaton recommends an excess of 1 percent of the diameter of the cylinder.

"A theoretical paper on Piston Packing Rings of Modern Steam Engines by O. C. Reymann will be found in the Journal of the Franklin Institute, August, 1897.

"Cross-section of the Rings.—The thickness is commonly made 1/30 of the diameter of cylinder + ⅛ inch, and the width = thickness + ⅛ inch. For an eccentric ring the mean thickness may be the same as for a ring of uniform thickness, and the minimum thickness = ⅔ the maximum.

"A circular issued by J. H. Dunbar, manufacturer of packing-rings, Youngstown, Ohio, says: 'Unless otherwise ordered, the thickness of rings will be made equal to 0.03 × their diameter. This thickness has been found to be satisfactory in practice. It admits of the ring being made about 3/16 inch to the foot larger than the cylinder, and has, when new, a tension of about two pounds per inch of circumference, which is ample to prevent leakage, if the surface of the ring and cylinder are smooth.'

"As regards the width of rings, authorities 'scatter' from very narrow to very wide, the latter being fully ten times the former. For instance, Unwin gives $W = 0.014\ d + 0.08$. Whitham's formula is $W = 0.15\ d$. In both formulæ W is the width of the ring in inches, and d the diameter of the cylinder in inches. Unwin's formula makes the width of a 20-inch ring $W = 20 \times 0.014 + 0.08 = 0.36$ inch, while Whitham's is $20 \times 0.15 = 3$ inches for the same diameter of ring. There is much less difference in the practice of engine-builders in this respect, but there is still room for a standard width of ring. It is believed that for cylinders over 16 inches diameter ¾ inch is a popular and practical width, and ½ inch for cylinders of that size and under."

(2) It is assumed that the paddle wheels were suitably designed so as to deliver the required thrust at the designed number of revolutions, also that at the designed revolutions the engines were developing the designed full power.

If the loss of buckets were evenly distributed around the entire circumference of the wheel, the effect would be similar to that resulting from too small an immersion of the wheel or from fitting buckets of insufficient area. The thrust delivered by the wheel would tend to decrease, the revolutions to increase above the designed and the slip to become excessive. The speed of the vessel would fall off.

If, as seems more natural, several consecutive buckets were lost the thrust would tend to decrease and the speed of rotation increase over the designed when this portion of the wheel was in the water and during the remainder of the revolution the thrust would tend to increase and the speed to decrease approaching the designed figure. Such changes in thrust and speed of paddle wheel would result in serious variation in engine revolutions which would develop heavy periodic stresses in the reciprocating parts and engine frame. The speed of the vessel would fall off as in the previous case.

It is practice to make all buckets on a paddle wheel of one size and type. The fly wheel action of the heavy paddle wheel aids in reducing the peripheral variation in speed. However, unless multiple cylinders are installed, it is impossible to avoid wide variation in crank effort. When all buckets are of the same size, excess torque produces increased slip (the individual bucket being designed for average torque). Were bucket areas proportioned to torque, the thrust against the water would also be proportional to torque and the vessel would be subjected to a marked impulse every revolution of the wheel similar to that produced upon a row boat by the stroke of an oar. Such an arrangement would involve undue strains upon machinery and foundations, would be uncomfortable for passengers and would probably be wasteful of power due to the alternate acceleration and retardation of the ship.

Assuming proper design, as originally stated, the care and adjustment enjoined by good engineering practice is all that could be suggested on the basis of the information furnished. Material improvement in balance is probably a matter of considerable expense, if possible at all.

(3) The methods described in the writer's reply to Q. 1124, July, 1921, page 563, should be of assistance in lining up your engine.

Density of Boiler Feed Water—Point of Cut-Off—Numbers on Engineers' Licenses

Q. (1143).—(1) If sea water is taken as containing 5 ounces solid matter per gallon, or 1/32 of its total weight, what is the working or usual upper limit allowed for working a Scotch boiler for density? For a Babcock & Wilcox boiler?

(2) When it is stated that the cut-off of a cylinder is 0.625, does this mean that the piston has traveled 0.625 of its total stroke when cut-off occurs, or does it mean that 0.625 of the stroke has yet to be completed?

(3) In the upper corner of an engineer's license there are numbers written in, such as 1-1 or 3-4. What do each of these numbers refer to?

A. (1143).—(1) For good operation of Scotch boilers when salt water is used for make up feed, the saline density should be maintained between 1/32 and 2/32, the 1/32 preferred if possible. Sea water contains magnesium chloride which, when heated, decomposes, liberating hydrochloric acid,

which causes rapid corrosion of iron and steel. It has been found by experiment that, when the brine salinity is allowed to go above 4/32, large quantities of the acid are given off and cause corrosion in a very short time. In addition to the hydrochloric acid danger, there is in sea water a considerable amount of air and some carbonic acid gas. These also cause serious corrosion; this cannot be prevented, but is obviated to some extent by placing an air chamber at the main feed heater outlet, to serve as a collector and air and gas split off. Furthermore, when the boiler and fittings are made, some parts of iron or steel and others of composition, corrosion takes place from electrolysis (battery action, decomposing the steel or iron). Zinc protectors are usually placed within the boiler to counteract this trouble. With reference to watertube boilers, as a rule, when sea water is being unavoidably admitted to the boiler, blowing down should not be resorted to until the saturation exceeds 600 grains of chlorine per gallon in Babcock and Wilcox or fire tube boilers, 300 grains in Niclausse boilers, and 150 grains in small bent-tube or torpedo boat boilers. (Sea water contains more than one pound of salt for every 32 pounds of sea water, or about 1,850 grains of salt per gallon.)

(2) Cut off is that point in the stroke of a reciprocating engine at which the admission of steam to the cylinder is stopped. Its position in the stroke is expressed as a ratio between the distance already traveled by the piston when cut off takes place and the total travel or stroke of the piston.

(3) Prior to 1900 or 1901 marine engineers' licenses were issued annually. Since that time they have been issued for periods of five years. The first of the figures instanced refers to the number of licenses issued under the old system and the second to those issued under the new. Thus the figures 3-4 would indicate that the engineer had been licensed for a total period of 23 years.

Apertures in Deadwood of Twin Screw Vessels

Q. (1145).—What is the latest practice regarding the fitting of apertures in the deadwood of twin screw vessels, and any alleged advantages or disadvantages of the same?

A. (1145).—Present practice in this country and in England does not favor fitting apertures in the deadwood of twin screw vessels. The tendency seems to be rather toward increased tip clearance (the shortest distance of propeller blade tip from surface of hull).

In a series of eighteen high speed vessels, all of similar type, the first of which was designed about 1908 and the last ten years later, the ratio of tip clearance to propeller diameter increased gradually from about 0.18 to 0.28.

In another series of ten medium speed vessels, the first designed in 1906 and the last in 1919, this ratio increased from 0.15 to 0.20 in the case of ships with large, slow turning wheels and from 0.20 to 0.26 or more for vessels with smaller and faster wheels.

While no apertures were fitted in any of the above cases the deadwood immediately forward of the rudder post was generally cut away below the level of the propeller shafting. This permitted the use of balanced rudders and gave decreased turning circle.

For slow full bodied vessels the same tendency toward increased tip clearance exists but the keel is usually carried aft without break to take the lower rudder pintle.

The following discussions relative both to apertures and to tip clearance are in general agreement with the foregoing and cover the principal advantages and disadvantages involved.

Holms in "Practical Shipbuilding," edition 1918, page 253, writes:

"In a few cases an aperture has been introduced so that propellers may overlap, and thus allow the shaft to be placed nearer the center line. The arrangement is advantageous in that the bossed portion of the vessel's side is less extensive, the length of the propeller brackets is reduced and the strength of all parts is increased; it is not now adopted, however, as it is found to cause excessive vibration."

Taylor in "Speed and Power of Ships," edition 1910, page 243, writes:

"It is undesirable to place screws so that their tips are too close to the surface of the hull. When a screw tip strikes the belt of eddying water adjacent to the hull, the virtual blows resulting are communicated to the ship, shaking rivets loose and causing vibration. The irregular forces upon the propellers also cause vibration of the ship.

"In some twin screw ships this trouble has been partially avoided by having an opening in the deadwood abreast the propellers. This saves the ship and with large propellers of moderate speed of revolution the tips can be brought quite close to one another without giving trouble. For small, quick turning propellers, such as those fitted with turbines, vibrations are very likely to be set up unless the blade tips are kept well clear of the hull, say 30 inches to 36 inches. It seems a pity to lose any of the beneficial action of the wake and it is possible that, if the hull abreast the propeller tip were made of circular shape, with the shaft as a center, specially strengthened to stand the pounding, and the propeller tips fitted close to the hull so that they caught the dead water through a large arc, the beneficial effect of the wake might be had without very objectionable vibration, though such propellers would probably be noisy. That is a matter, however, which could be determined only by a full sized trial. The only solution now known to be successful is to keep the blade tips well clear and accept the slightly reduced efficiency."

NEW BOOKS

Wharf Management—Stevedoring and Storage

Reviewed by C. H. Peabody, Dr. Eng.

Wharf Management—Stevedoring and Storage. By MacElwee and Taylor. Size, 6 inches by 9 inches. Pages, XX + 350. Illustrations, 301. New York: D. Appleton and Company.

This is the first book on the subjects discussed and the authors, who appreciate that the treatment is suggestive and not exhaustive, in it blaze the way for future study of the problems which are numerous and complicated.

Ships, shipping and all things concerning them are conservative; after the Phœnicians and their successors had spent a few thousands of years dealing with the sea they thought they knew something of its moods. The simplicity of the ancient methods of loading ships persists in places to the present day. Under some conditions such methods may be the most efficient, as when a river steamer noses into the levee and the roustabouts swarm ashore and file on board with sacks and bales on their backs. But when we realize that even a fairly active steamer may spend half her time in port and that it may cost as much to handle a package discharged from a ship as to carry it on a sea voyage we begin to understand the importance of this book. Stevedores seldom break out into literature and we can understand why it is necessary at this day to blaze the way. To be explicit, we may note that the expenses of a freighter in port may be $2,000 to $4,000 a day; ships must be loaded and unloaded, and this cannot be unduly hurried; but in a sense a ship is earning money only when at sea.

This work does not deal with the design and layout of wharfs, but at the beginning some ideas are necessary in order to understand the discussion of their management. In America we are accustomed to long narrow wharfs which

sufficed for the days of sailing ships but which now lead to all kinds of congestion and inconvenience. Perhaps the worst condition is found in New York City, which by some fatality has the blocks turned crosswise; the north and south avenues having short blocks and the east and west streets, long blocks. Following this condition and the riparian city rights the wharfs conform to the streets on both North and East rivers, and both wharfs and slips are very inconveniently narrow. Contrast this with the European quays with the ship lying broadside on and discharging from all the hatches to land directly, though the quays also have their own problem in handling cargoes.

Lighterage is found in greatest development in New York City and in some South American ports; for the latter the great difficulty of building wharfs and the comparatively light commerce control conditions; for New York the natural lay of the land on a long narrow island is the dominant feature. There is one advantage in lightering, namely, that freight from any railroad may be delivered to any wharf; when the freight is lightered in railroad cars the conditions are not so bad. The lack, or the impossibility, of a belt line road calls for an excessive amount of trucking; and the trucking may cost a tenth of the worth of certain packages. The antithesis of this condition is found on our Great Lakes in the handling of iron ore, which runs into the ships' holds in streams and is dug out by giant clam-shell buckets.

The administration of the work on the wharf is under the superintendent, with his clerical force and checkers, who must keep proper account of each and every item of freight, and the stevedore with his longshoremen who handle the freight; a good stevedore may be worth too much as such to be promoted to be superintendent, for he is the man who sees that the freight goes in and that it does not shift. Longshoremen are too often recruited from drifting unskilled labor, whereas it takes skill for a man to throw a sack of flour into proper stowage or to induce a barrel to settle in its proper place.

There are two ways of transferring freight to the hold of a ship, (a) through side ports and (b) down hatches. The first is proper for coastwise, Great Lake and river steamers, especially with package freight; the second is almost universal for deep sea ships. The greater part of loading through side ports is by hand trucks, and that goes well enough so long as there is little or no tide so that freight moves horizontally; on the seaboard where there is large rise and fall of tide the labor becomes slow and excessive. A makeshift arrangement is to run by power an endless chain onto which the truckman may hitch and get help uphill. A more completely mechanical method is to have a traveling belt or chain with cross-cleats or pockets into which packages are thrown or placed and which empties them out at the end of the run.

Seagoing ships are habitually loaded through hatches; formerly the hoisting was done by hand power, then a horse was used and lately steam power or electric power. The American system puts the hoisting onto the ships which have masts and cargo booms, usually two booms to a hatch; in consequence wharfs are poorly supplied with hoisting appliances unless in the form of cranes or derricks for specially heavy pieces. Modern winches are rapid and handy, so that one man may work two booms with right and left hand levers. Electric winches are adaptable to motorships; they must be rugged and watertight; they have the advantage of not wasting energy when idle.

A simple but very important matter is the method of hand signaling; this must be simple and positive and should be completely standardized.

A load for a winch is called a draft; it may be a single piece or a bunch; the weight of a draft may be 1,000 or 2,000 pounds. A common method is to wrap a rope sling around a piece or a bunch, slip one loop through the other and catch onto the hook hanging from the boom; or articles may be packed on a platform and all hoisted together.

For heavy pieces of freight a locomotive crane is convenient, running on rails to the place where it is needed. When the volume of such freight is sufficient a gantry crane may run along the face of the wharf. Very heavy pieces like locomotives are conveniently loaded by tower cranes. If cranes are used intermittently the overhead becomes excessive.

The stevedore must have wide experience and a high degree of intelligence to trim the cargo so that the ship shall float erect on an even keel; and further, he must control the center of gravity so that the ship shall be neither stiff nor cranky. A ship properly stowed should have the hold full and be down to her lines; usually a mixed cargo is required for this end; ships like ore carriers or colliers are designed to properly control the stability. Frequently ships that are properly stowed when at sea may become cranky in harbor during unloading and numerous accidents have happened in such cases.

There are indeed rules for insuring safety of the ship and its cargo; unfortunately they emanate from various sources, government laws, city and state regulations and the rules of classification societies. These rules are liable to be insufficient, inconsistent or contradictory. In too many cases regulations may be evaded if accidents are avoided. It would appear that some system of inspection should be possible to forestall evasion.

The importance of loading and unloading rapidly has been emphasized; when a good system is used effectively a ship can discharge cargo faster than it can be cleared from the wharf or quay; again it is necessary to accumulate freight for a ship and to have it properly sorted. A warehouse is essential for both purposes and should be worked in conjunction with the delivery of freight by trucks, railroad or lighters either to or from the ship. The smooth working of such a complicated system without hitch or interference calls for a correct plan, proper equipment and high administrative ability. Hand trucking to or from a warehouse becomes expensive and ineffective; it should be replaced or supplemented by electric traction of some type. A very flexible traction is by an electric truck with several trailers. The trailers may be loaded individually, made into trains and delivered where required. Such a train may run anywhere on the warehouse floor or wharf. A monorail track may be installed overhead out of the way and work quickly and effectively; it requires more head room and is not so flexible. Electric elevators for warehouses are worked by push buttons which deliver the cage very near the proper floor; an automatic electric device quickly adjusts the cage accurately to the floor.

The floors of a warehouse have good head room and goods must be properly tiered to use the room and avoid danger to containers and contents. This, together with the necessity for assorting the goods for convenience and accessibility, calls for intelligent planning and efficient superintendence. So simple a matter as turning each package so that its tag can be seen has its importance.

When we consider the variety, importance and complexity of the subjects treated in this book we appreciate the work of the authors in blazing the way.

An Investigation of the Fatigue of Metals is described in a 185-page pamphlet by H. F. Moore, research professor of engineering materials, and J. B. Kommers, research associate professor of engineering materials, published by the University of Illinois, Urbana, Ill., giving complete results of an investigation of this subject covered by the Engineering Experimental Station, University of Illinois, in cooperation with the National Research Council of the Engineering Foundation and the General Electric Company.

PERSONAL MENTION

Jasper Moon has been appointed manager of the Booth Steamship Company, Ltd.

W. L. Johnstone has been made assistant general passenger agent of the Pacific Mail Steamship Company, San Francisco, Cal.

A. T. Nott has been appointed superintendent of terminals for the Los Angeles Steamship Company. Mr. Nott was formerly dock agent for the company.

P. H. Lacy recently succeeded C. H. Marshall as district director of the United States Shipping Board at Savannah, Ga. Mr. Lacy was formerly district director at Boston.

P. K. Crocker, superintendent of European trades of the Shipping Board's traffic department in New York, has been appointed assistant to George H. Wells, traffic manager.

H. C. Cantelow, formerly with the Pacific Steamship Company, has been appointed Pacific Coast manager of the Luckenbach Steamship Company, Inc., with headquarters in San Francisco.

Hugh Gallagher, formerly general eastern representative of the Pacific Steamship Company, has become passenger manager of this company in California, with headquarters at San Francisco.

Captain R. C. Brennan recently assumed his duties as port captain for the Admiral Line at Seattle, Wash. He has just spent two years in the Orient as supervising port captain for the company.

William Altmansberger has been made superintendent of hulls and machinery of Geyelin and Company, Inc., at the Philadelphia office. Mr. Altmansberger has been connected with the Earn line and with the United States Salvage Association.

E. S. Leavitt has been appointed general agent of the Southern Pacific Railroad and the Morgan Line in Boston to succeed J. H. Glynn, deceased. Mr. Leavitt was manager of the traffic department of the Shipping Board in Boston for a period of four years and prior to this time was connected with the Southern Pacific.

George M. Skinner has been appointed manager of maintenance and repairs for the United States Shipping Board in San Francisco, Cal. At the present time Mr. Skinner is conducting a survey of the Pacific Mail liner *Empire State* in connection with the application made by the company to increase the present steerage capacity from 300 to 600 accommodations.

Norman F. Brown, formerly director of public works of Pittsburgh, Pa., has been elected vice-president and director of the Dravo Contracting Company, Pittsburgh, Pa. Prior to his connection with the city of Pittsburgh, Mr. Brown was assistant to the chief engineer of the Pennsylvania Railroad. During the war he was commissioned a major in the transportation corps of the American Expeditionary Forces.

Roger D. Lapham has been made a member of the firm of McCormick and McPherson of San Francisco, Cal. This company, which hereafter will be known as McCormick, McPherson and Lapham, has been appointed Pacific Coast agent for the Texas Oil Company. Mr. Lapham was for many years connected with the American-Hawaiian Steamship Company, first as agent in Seattle, then in Los Angeles and later as assistant traffic manager in San Francisco.

Captain Sir Bertram Hayes, of the White Star Liner *Olympic*, was recently given the title of commodore of the White Star fleet. In May, Captain Hayes will assume command of the new liner *Majestic* on her maiden trip in the New York-Southampton service of the White Star Line.

Richard H. Farley has been made passenger traffic manager of the International Mercantile Marine Company, New York. At the same time Thomas R. Thorne and D. D. Weipert were appointed assistant passenger traffic managers in charge of the first and second class departments and David Lindsay as assistant in charge of the third class department. Mr. Farley succeeds W. W. Jefferies, passenger traffic manager since 1906 and a member of the organization since 1882.

William M. Kennedy, who, as announced in the March, 1921, issue of Marine Engineering and Shipping Age, resigned as general works superintendent of the Chester (Pa.) yard of the Merchant Shipbuilding Corporation to accept a position with the repair department of the United States Shipping Board, has been appointed supervising local manager, North Atlantic district, of the Shipping Board vice J. J. Eason, resigned. Mr. Kennedy has had twenty years' experience in various branches of the shipbuilding industry, having served in various capacities with some of the largest private shipyards as well as in the Navy yards.

OBITUARY

John A. Donald, one of the original members of the United States Shipping Board, died at Rye, N. Y., on the morning of December 13, 1921, from an attack of pneumonia. He was selected as a member of the Board by President Wilson and took office in the spring of 1917, just at the time of our entry into the Great War. He was the only member of this Board who had had any shipping experience. Although born in Scotland, he came to this country in 1888 and took out his citizenship papers as soon as practicable. He spent his entire life in the shipping business and at the time of his appointment had organized and become president of the Donald Steamship Company. Although taking up public office at a time in life when he could have retired and spent the remainder of his life in ease, he devoted his untiring energy to the needs of the country in shipping which became of such vital importance during the war. His many years of experience proved of inestimable value to the Government in the performance of the responsible duties which were thrust upon him. Throughout the entire war and until the end of his term he devoted his time, energy and health to his country's demand. Many men, much younger than he, broke down under the terrific strain of public duties in those days, when the best each man had in him was required in the interests of the nation. Mr. Donald left office with his health shattered but with the consciousness of having performed his part in the great conflict to the uttermost of his ability. It was frequently a cause of wonderment of his confreres how he could bear up under the burdens which were placed upon him. His death at a time when he should have been enjoying a well-earned rest marks Mr. Donald as one of the sacrifices of the Great War as truly as though he had fallen on fields of Flanders. Mr. Donald was well and favorably known to the shipping public throughout the land. His patriotism and courage were inspiring to those associated with him. His genial disposition and his unfailing willingness to help all who applied to him for assistance will be greatly missed by his hosts of friends. His mortal remains were interred with appropriate ceremonies in the old Moravian cemetery, on the side of Staten Island hills, overlooking the sea, which he loved so well.

Shipping and Ship Operation News

Changes in Steamship Routes — Passenger and Freight Activities—Port Plans and Other Notes of General Interest

Steamships Brabantia and Limburgia Bought by American Ship and Commerce Corporation from Holland Lloyd Line

Biggest American Shipping Transaction Consummated—Steamers Are of 20,000 Gross Tons Each—Will Be Operated by United American Lines Between New York and Hamburg

ONE of the biggest transactions in the history of American shipping is seen in the announcement that the American Ship & Commerce Corporation, of which W. A. Harriman is chairman, has purchased the well-known passenger steamers *Brabantia* and *Limburgia,* of 20,000 gross tons each from the Royal Holland Lloyd Line. It is planned that these vessels will be transferred to the American flag at once, and that they will be placed in operation in the North Atlantic.

The *Brabantia* and *Limburgia* were built in Germany originally to the order of the Hamburg-American Line. They were in the course of construction when the war broke out. Work on them was suspended for a time, and they were not completed until 1920. Before the ships were finished they were sold to the Royal Holland Lloyd, under whose flag they first went into service.

The steamers are similar as regards general design and equipment, though differing in certain measurement details. The *Brabantia* is 596 feet long, has a breadth of 72.3 feet, and a depth of 40.2 feet; the *Limburgia* is 592 feet long, having a breadth of 72.3 feet and a depth of 39.7; both are oil burning, triple screw steamers of 17.5 knots speed. They have passenger accommodations for about 400 first class, 260 second class and 900 third class.

They will be operated between New York and Hamburg, with calls at French and English Channel ports. They will fly the house flag of the United American Lines, which is the operating organization for the American Ship and Commerce Corporation.

MOTOR BOAT SHOW

17th Annual Exposition at Grand Central Palace February 17-25

With the most successful automobile show ever held in New York City ended, interest in engines and motors turns to the 17th annual exposition of motor boats to be held in Grand Central Palace, February 17 to 25. This show holds the same important position in the motor boat world as the automobile display does in the motor car industry. Both are affiliated in many ways, and there are hundreds of persons who own and drive their own automobile, who also own and operate their motor boat.

The National Association of Engine and Boat Manufacturers, Inc., did not schedule a show last year because at the time such a display could have been held, Grand Central Palace, where the organization wanted to stage its exposition, was not available. As a result the interest in what the boat and engine builders will have to show this year is greater than ever. There will undoubtedly be new ideas in body building in the large cruisers. Speed craft will also attract because in this class of boats, engines of large horsepower figure just as much as body design. Runabouts which are the most popular craft in the nearby waters, of Sheepshead, Jamaica and Gravesend Bays will be displayed in large numbers.

During the past few years model yacht racing has become a most popular sport and the engine and boat manufacturers have recognized this. In fact, the international races between these miniature craft have become so important that the Central Park Model Y. C. is building fifteen class "B" boats for the elimination races to pick a defender against the boats W. J. Daniels, of England, will send here next summer. The Prospect Park Model Y. C. will have entries in these elimination contests, while the Montclair Model Y. C., the Irvington Model Y. C. and the Tacoma Model Y. C. have also entered the lists. The races will be held in June.

STEAMSHIP INTERESTS

At a recent conference with President Harding, attended by Secretary Hoover, and Mr. Lasker, over shipping rates for the Congressional Relief of Russia, the following arrangement was reached:

The Shipping Board would undertake to transport at cost, but American private shippers should be given priority in employment over the Shipping Board steamers so long as they were willing to quote fair rates.

It was considered that $1.50 per ton or so above going rates for foreign shipping represented approximately the difference in costs imposed upon American shipping by American shipping law and American wages and that approximately this figure should be used as a criterion in determining fair rates for private American shipping. The cooperation of the majority of American shipowners has been assured.

The United States Shipping Board has announced the allocation of sixteen vessels ranging in size from 4,145 tons to 10,914 tons, to various ocean and coastwise steamship line.

Three electric drive ships are now on the high seas on long voyages and latest wireless reports indicate that all are making satisfactory progress. The vessels are the *Archer* and the *Eclipse,* operated by the Barber Line, and the *Victorious,* which was recently allocated to the Black Diamond Line.

The Eastern Steamship Lines, Inc., have established a daily freight service between Boston and New York, which will be maintained by the steamers *H. F. Dimock, Herman Winter, Norwalk,* and *Delaware.* This is the first time that a daily strictly freight service has ever been attempted between Boston and New York, and it will be maintained all through the winter, according to present plans.

Old Dominion Transportation Co. May Purchase Vessel for Addition to Passenger Service Opening in Spring

Steamers "Hamilton" and "Jefferson" to Be Refitted for Resumption of Run Between Norfolk and New York—Line Suspended Since 1917 Responds to New Demand

BOAT passenger service between Norfolk and New York, suspended since 1917, is to be resumed this spring, the Norfolk Chamber of Commerce announced, and the steamers *Hamilton* and *Jefferson* are to be refitted as passenger steamers to be ready for the opening of the season.

Purchase of a third vessel by the Old Dominion Transportation Company is probable.

The *Hamilton* and *Jefferson* were passenger vessels until 1917 when they were taken over by the government, stripped of staterooms and converted into freight ships. When the Old Dominion Transportation Company was formed last year the ships were put on as freight carriers. It is stated that increased demand for additional passenger service has prompted the change.

Optimism for 1922 Expressed at Annual Conventions of Marine Engineers and Supplymen at Washington, D. C.

Outlook for Year Considered More Favorable—Delegates Hear Addresses and Call on President Harding—Smoker and Theatre Parties Entertain the Visitors

The forty-seventh annual convention of the National Marine Engineers Beneficial Association was held at the Hotel New Ebbitt, Washington, D. C., January 16-21, in conjunction with the annual convention of the Marine Engineers Supplymen's Association at the Raleigh. During the course of the engineers' convention the delegates were received by President Harding at the White House, and although the various representatives reported having gone through a period of severe business depression during 1921, there was considerable optimism expressed over the prospects for substantial improvement in 1922. Following are the association's officers for 1922: William S. Brown, president; William H. Hyman, vice-president; Samuel J. Hogan, conductor; J. E. Purdee, Chaplain; D. P. McCracken, door keeper; C. M. Sheplar, executive committee; William J. Barrett, executive committee.

President Brown called the convention to order at 9:30 A. M. on Monday, January 16, at the Ebbitt House and after the formal procedure of credentials and similar matters, Mr. Brown introduced Secretary of Labor Davis who was followed by General Wehler. There were about 350 officers, delegates, representatives and their wives in attendance.

On Wednesday the entire convention was escorted in a body to the White House where they were received by President Harding and on Wednesday night the France Packing Company entertained the ladies with an elaborate "Ladies Evening." The social event of the convention, a smoker, was tendered the delegates on Thursday night, January 19, by the Marine Engineers Supplymen's Association at the Willard Hotel, the ladies spending the evening at theatre parties.

Washington was selected as the convention city for 1923. As the present officers' terms have not yet expired, there was no election. The Supplymen's Association, by unanimous vote, elected MARINE ENGINEERING AND SHIPPING AGE to membership.

Officers of National Association: Left to right, D. P. McCracken, Doorkeeper; Samuel J. Hogan, Conductor; William H. Hyman, 2nd Vice-President; William S. Brown, President; George A. Grubb, Secretary-Treasurer; C. M. Sheplar, Executive Committee; William J. Garrett, Executive Committee; J. E. Purdee, Chaplain

Officers and Delegates of Engineers and Supply Men's Conventions on U. S. Treasury Steps, Washington, D. C.

Shipbuilding and Terminal Development

What the Shipyards Are Doing—Dry Dock Notes—Launchings—New Engineering Projects

$3,704,000 Asked for Marine Work by Department of Plant & Structures of New York in 1922 Requirements

$1,100,000 Asked for Construction of New East River Ferryboats and $550,000 for the Purchase and Reconditioning of Others—Balance Is for Ferry Terminals, Equipment, Etc.

A TOTAL of $3,704,000 for various marine work in connection with the building of new boats, ferry terminals and equipment incidental thereto is asked by Commissioner Grover A. Whalen, of the Department of Plant and Structures of the City of New York, in his recommendations for funds for 1922 to the Board of Estimate and Apportionment.

Included in the recommendations is a request for $1,100,000 for the construction of new ferryboats for the East River, which will probably be propelled by steam of Diesel engines, $550,000 for the purchase and reconstruction of existing ferryboats and $325,000 for constructing a new floating drydock. The funds requested for marine work during the year include the following:

Construction of new ferryboats for East River	$1,100,000
Purchase and Reconstruction of existing ferryboats	550,000
Completion of ferry terminals, Whitehall Street	400,000
Construction of floating dry dock, Atlantic Avenue	325,000
Vehicular approach connecting marginal way, St. George terminal	225,000
Reconstruction of shop to handle shafts and other heavy work, Atlantic Avenue	200,000
Plaza in front of Whitehall Terminal	200,000
Construction of ferry slips at Whitehall Street	116,000
Three electric bridges, Whitehall ferry slips	100,000
Reconstruction, Atlantic Avenue ferry terminal	76,000
Reconstruction, Hamilton Avenue ferry terminal	76,000
Reconstruction, Fulton Street, Brooklyn, terminal	66,000
Reconstruction, Fulton Street, Manhattan, terminal	60,000
Reconstruction of street level, etc., South Street terminal	50,000
Widening Viaduct, Richmond Terrace, S. I., to upper level of terminal	40,000
Additional coal bunkers at St. George, S. I.	30,000
Reconstruction, North rack and coal pier sheds at Astoria	30,000
Removing old ferryhouse, Whitehall Street	20,000
Construction of derricks in connection with dry dock	20,000
Construction of fire house and moorings at St. George for fireboat	10,000
Construction of foot bridge from Whitehall terminal to Battery Park	10,000

Six Dump Scows to Be Built By Street Cleaning Department During Year

It is reported that the Department of Street cleaning, of the City of New York, will place during 1922 contracts for six wooden side-dumping scows, which it is believed will cost close to $50,000 each. It is understood that the department is in need of these boats and that definite action will be taken toward the issuing of plans and specifications as soon as the question of patent rights is definitely settled.

"Mongolia" Awarded to Tietjen & Lang Yard of Todd Shipyard Corporation

The contract for reconditioning the steamship *Mongolia*, of the International Mercantile Marine Company, has been awarded to the Tietjen & Lang plant of the Todd Shipyards Corporation. The work to be done on the ship has to do chiefly with the construction and complete equipment of new third class accommodations besides the various other work incidental thereto and is practically the same as that now being done on the steamer *Manchuria* of the same company, which contract was also awarded to the Tietjen & Lang yard last week.

It is believed that the total amount involved for reconditioning both ships will probably be in excess of half a million dollars.

Todd Shipyards Corporation Buys Land of Mobile Shipbuilding Company

William H. Todd, of the Todd Shipyards Corporation, having shipbuilding and ship repair plants on both the Atlantic and Pacific coasts, has purchased the land on which the plant of the Mobile Shipbuilding Company was located during the World War and two years afterward. The purchase price is said to be $130,000. An offer of $165,000 for the material on the yards of the plant which was under the control of the United States Shipping Board, has been made by Fitzpatrick & Till, and is now under consideration.

Japanese Tanker Is to Have Peabody Burners

The Peabody Engineering Corporation, 331 Madison Avenue, New York City, has been awarded the contract for the Peabody-Fisher wide range fuel oil mechanical burners for the tank ship, now in course of construction at the yards of the New York Shipbuilding Corporation, Camden, N. J.

$8,200,000 Is Total Amount Required For Complete Reconditioning of Leviathan; Newport News Company Low Bidder

President Powell, of the Emergency Fleet Corporation, Gives House Subcommittee Approximate Final Figures on Cost of Putting Ship in Service

The steamship *Leviathan* can be completely overhauled and put in condition for trans-Atlantic service for a total cost of $8,200,000 according to a statement of President Joseph W. Powell, of the Emergency Fleet Corporation, at a recent hearing before the Subcommittee of the House Committee on Appropriations at Washington, D. C.

"In estimating the cost of reconditioning the *Leviathan*," Mr. Powell said, "the following figures have been used: The Newport News Shipbuilding & Dry Dock Company bid for reconditioning and conversion of the vessel to burn fuel oil, $5,595,000. The Newport News Shipbuilding & Dry Dock Company bid for repairs and machinery of the *Leviathan*, $515,000. The bid of Gimbel Bros., for equipment of steward's department of the *Leviathan* was $539,000; allowance for library, not included, $15,000; cost of moving the ship to the contractor's yard, insurance covering moving vessel to the contractor's yard, dry docking for 30 days, new anchors and chains, moving of ship to dry dock, and cost of the trial trip, $627,000; maintenance of steamer and guarding ship for 14 months' period during reconditioning—you understand we have to have this big force on board taking care of her all the time that work is being done—$680,000; inspection during reconditioning, $225,000, making a total of $8,166,000.

"So far as it is humanly possible to foresee the work that is to be done its cost is covered by the above estimate, and I believe we are giving you a figure that is thoroughly justified."

Many New Vessels Are Proposed For Addition to Various Government Departments During Ensuing Year

Two Diesel Electric Coast Guard Cutters, Diesel Electric Seagoing Dredge and Several Lighthouse Service Vessels Are Pending—Request for $730,000 for Lighthouse Vessels Awaiting Final Decision

ACTIVITY in the construction, during 1922, of various vessels for Government service is indicated in latest reports received by MARINE ENGINEERING AND SHIPPING AGE. In this connection it is stated that the United States Coast Guard is making plans and has asked for an appropriation for the construction of two coast guard cutters, one of 1,200 horsepower and one of 2,400 horsepower. The boats are to be propelled by Diesel electric engines, one to be equipped with four sets of 600 horsepower each, and one to be equipped with two sets of 600 horsepower each.

The War Department, it is understood, is preparing plans and specifications for a seagoing dredge 246 feet long, to be equipped with Diesel electric drive of six units of 500 horsepower each, or a total of 3,000 horsepower.

LIGHTHOUSE VESSELS

According to the Commissioner of Lighthouses of the Department of Commerce, careful estimates and examinations as to the condition and further serviceability of vessels of the Lighthouse Service, it is found that sixteen light vessels and eleven tenders should be replaced within the next five years. Fifteen of these vessels are urgently needed.

NEED OF NEW SHIPS

Several of the older lighthouse tenders, the Commissioner reported, have reached the point where because of age and deterioration their usefulness and seaworthiness are impaired and they are greatly in need of replacement, being beyond economical repair. It is considered necessary to construct at least two tenders each year to maintain the fleet in an efficient condition.

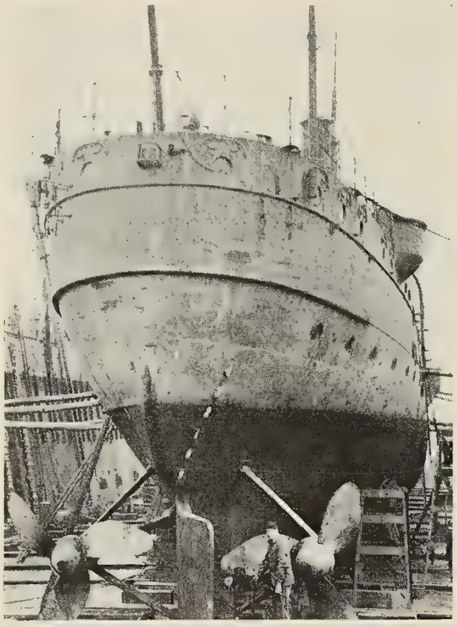
For the construction of new lighthouse vessels, a request for $730,000 is now pending before Congress. This amount is a reduction from $1,500,000 originally requested for two tenders and four light vessels. The Commissioner states that the Lighthouse Service maintains light vessels at forty-nine stations.

Former Spanish Warship Isla De Luzon, Captured at Manila Bay, Is Reconditioning for Salvage Service

The former warship *Isla de Luzon* is in drydock at the plant of the New York Harbor Dry Dock Corporation, Rosebank, Staten Island, N. Y., undergoing repairs and general overhauling in preparation for service as a salvage vessel. In addition to general alterations in accommodations and removal of gunboat equipment, she is being fitted with a new mast and derrick gear for handling heavy loads, and is also having heavy towing equipment installed.

Isla De Luzon's Bow Ram

This interesting vessel was built at the yard of Messrs. Swan, Hunter, and Wigham Richardson, at Newcastle-on-Tyne, England, in the year 1887, for the Spanish Government. She saw service in the Spanish American war where she was captured by Admiral Dewey at the battle of Manila Bay. She was later sold out of the United States Navy, and is still good for many years of useful work. She is in remarkable condition for a vessel of her age, and belongs to Sloan Danenhower & Company, of New York City, who are supervising her fitting out as a salvage vessel. The vessel is twin screw, propelled by two triple expansion engines working horizontally. Steam is supplied by four Scotch boilers. She is 192 feet long by 30 feet beam.



Stern View

London Steam Turbine Company Takes Over Steam Motors Company

The officers of the Steam Motors Company, having the belief that the Steam Motor is the best machine of its class in the market and realizing that it would be necessary to increase its capital in order that the Steam Motor should take its proper place in the industrial world, have on January 1, 1922, sold to the London Steam Turbine Company of Troy, N. Y., all of its assets, patents and interests, and from this date the Steam Motors Company will be known as the London Steam Turbine Company, of Troy, N. Y.

Mr. London, who was the president of the Steam Motors Company, and a turbine engineer of international reputation, will occupy the same position in this company.

Mr. DeLeon, the vice-president and general manager, brings to the company an experience of twenty-five years as a manufacturing executive with some of the largest concerns in the country.

Construction of Eight New Ships Is in Prospect for the Near Future

It is reported that the Eastern Steamship Company, of Boston, in conjunction with the Clyde Line, of New York, is contemplating the construction of two passenger ships, which it is expected will cost close to $2,000,000 apiece. Although complete details with regard to these ships are lacking at present, it is understood they will be about 420 feet in length and oil burning.

TO BUILD SIX MOTORSHIPS

The firm of Whittlesey & Whittlesey, naval architects, 17 Battery place, New York City, has issued plans and specifications for the construction of six combination cargo and passenger Diesel motorships. The ships are to be 225 feet in length; the engines of about 1,500 horsepower, driving the vessels at a speed of about 13 knots. The new ships are for the Tri-National Steamship Company, 17 Battery place, New York.

Marine Construction News of the Month

Ship Contracts — New Ship Concerns and Shipyard Improvements—Terminal Projects—Government Contracts

SHIPS AND SHIPBUILDING

New Feed Pumps, San Francisco, Cal.—It is reported that two new feed pumps will be installed in the Shipping Board steamer Golden State.

Speed Boat Contract, Neponset, Mass.—A contract for a 60-foot speed express runabout, designed by Henry J. Gielow, Inc., naval architects and marine engineers, 25 West 43rd Street, New York City, has been awarded to the George Lawley & Son Corporation. The boat is to be equipped with two 150-horsepower speedway motors to develop a speed of 27 knots.

Overhauling Job, Jacksonville, Fla.—The steamship Cuba, of the Peninsula & Occidental Steamship Company, plying in the Key West to Havana route, has been placed in dry dock at the plant of the Merrill-Stevens Dry Dock & Repair Company, to be scraped, painted and overhauled. The ship was put in service last February and this is the first time she will be in dry dock since being turned over by her builders.

General Overhaul, San Francisco, Cal.—The steamer Hanawa, a vessel of 12,000 tons, built for the United States Shipping Board and which has not yet been in commission, has been towed from her anchorage where she lay idle since her completion last June, to the Bethlehem shipyards at San Francisco, prior to being chartered by the Shipping Board to the Columbia Pacific Shipping Company, of Portland, Ore.

Shipbuilding Boom, Essex, Mass.—According to reliable information at least a dozen vessels to be added to the Gloucester fishing fleet will be ordered during the coming year. One of these craft is already on the stocks, work on the molds of another is going on, two others are a certainty and approximately eight more are planned. At the yard of J. F. James & Son the construction of the schooner Puritan is now well under way, and at the Arthur D. Story shipyard the preliminary work is being completed on the new craft for Captain Clayton Morrisey, patterned after the old Oriole. Plans are also being prepared for the construction of a new vessel for Captain Morton Selig, and Captain Ernest Parsons is to have a vessel built at Essex this winter.

Steel Piping Contract, Chester, Pa.—It is announced by J. L. Ackerson, vice-president, that the Merchant Shipbuilding Corporation has been awarded a contract by the Frederick Snare Corporation of New York for the furnishing of approximately six and a half miles of riveted steel piping, weighing about 10,000 tons, part of the extension line of the Catskill Aqueduct. The section contracted for extends from the neighborhood of Cold Springs to Ossining, New York. The contract amounts to more than half a million dollars.

Vessels to Be Overhauled, Jacksonville, Fla.—The steamship City of Miami, owned by the Havana-American Steamship Company, has been placed on the dry dock of the Merrill-Stevens Company to be scraped and painted and made ready for the winter Miami-Havana run. The big ferry steamer Joseph R. Parrott, which is operated by the East Coast Car Company between Key West and Havana, is also at the yard of Merrill-Stevens awaiting her turn to be placed in dry dock.

Reconditioning Contract, Brooklyn, N. Y.—The contract for reconditioning the All America Cable Company steamship Relay, bids for which were opened recently, has been awarded to the Tebo Yacht & Basin Company. Among other things, three boilers are to be installed in the ship, the prices for which were were not included in the figures submitted for hull and other work. The job amounts to $58,470.

Contract Award, Hoboken, N. J.—Bids for reconditioning the steamship Manchuria were opened in private at the offices of the International Mercantile Marine Company, New York City, on January 5. It was announced that the contract has been awarded to the Tietjen & Lang Yard, of the Todd Shipyards Corporation. It is believed the cost of the work will be in excess of $250,000. The principal work involved in the contract has to do with the construction and complete equipment and finish of new third-class accommodations and various other work incidental thereto.

May Purchase Steamers, Chicago, Ill.—It is reported that the Great Lakes Traffic Corporation is considering the purchase of ten ocean-going steamers, to be used in its Great Lakes service between Chicago, Ill., and Buffalo, N. Y.

Repair Job, Victoria, B. C.—Yarrows, Ltd., has been awarded the contract for repairs to the Government repair steamer Givenchy, which struck and was submerged for six weeks near Bella Bella three months ago. The work will cost about $10,000.

Steel Hull Contract, Manitowoc, Wis.—The Manitowoc Shipbuilding Corporation has a contract for the construction of a new steel hull for the tug J. H. Meyer. The vessel will be 99 feet over all, 22 feet beam and 12 feet 6 inches in depth. Although the present machinery will be used in the new hull, some replacements will be necessary.

To Remodel Steamship, Vancouver, B. C.—The Wallace Shipyards were awarded the contract for remodeling the steamer Admiral Farragut, the company being the lowest bidder at a price of $63,250. The work will require sixty days. After the Admiral Farragut is remodeled the Admiral Watson will undergo a general overhauling at the same yards.

Steamer Repairs, Hoboken, N. J.—The W. & A. Fletcher Company has been awarded the contract for the repair of the steamship Mount Clinton at a price of $6,000. The work includes hull and bottom damage repairs. The same yard has also been awarded the steamship Antietam, by the Shipping Board, for dry docking and overhauling of sea valves.

Two Passenger Ships, Boston, Mass.—It is reported that the Eastern Steamship Company, of Boston, in conjunction with the Clyde Line, of New York, is contemplating the construction of two passenger ships, which it is expected will cost close to $2,000,000 apiece. Although complete details with regard to these ships are lacking at present, it is understood they will be about 420 feet in length and oil burning.

New Ferries, New York.—In its requisition to the Board of Estimate and Apportionment for funds required during 1922 in order to carry out present plans, the Department of Plant and Structures of the City of New York asks $3,704,000, of which sum $1,100,000 is for the construction of new ferryboats and $550,000 for the purchase and repair of others.

May Build Barges, Rochester, N. Y.—The Rail and Canal Transportation Company is said to be contemplating having built eight 600-ton wooden canal barges for use on the route through the Erie Canal. As the company's trade involves long hauls, it is expected that a departure from the usual box-like design of the ordinary canal barge will be made and a shaped bow and stern adopted.

Will Construct Lake Steamer, Port Arthur, Ont.—The Port Arthur Shipbuilding Company has recently closed a contract for the construction of a lake steamer for the Mathews Steamship Company, which is to be ready for launching in October, 1922. The vessel is to be a steel freighter, 550 feet long. The company has placed 800 men on its pay roll to do the work on this ship, the material for which is being rushed to the head of the lakes as quickly as possible.

Reconditioning Ship, Hoboken, N. J.—The contract for rebuilding the engine foundations in the Hudson River steamship Hendrick Hudson has been awarded to the W. & A. Fletcher Company at a price of about $5,000.

To Purchase Steamer, San Francisco, Cal.—It is reported that F. M. Stark, vice-president of the Stark Steamship Lines, Inc., plans to purchase a 6,000-ton steamer for operation in the San Francisco-Portland service. Negotiations are now under way.

Diesel Engine Contract, San Francisco, Cal.—The Pacific Diesel Engine Company has been awarded the contract for building and installing two 525-brake horsepower Werkspoor Diesel engines in the automobile ferry now being constructed for the Golden Gate Ferry Company at the James Robertson Shipyard, Alameda, Cal.

Engine Installation, San Francisco, Cal.—The hull of the steamer Thomas Rolph, owned by George E. Billings, is at the China Basin plant of the Main Iron Works, undergoing engine installation. The vessel will be equipped with 1,000 horsepower triple expansion engines and will have a steaming radius of twenty days. When completed the vessel will carry about 1,400,000 feet of lumber.

Steamers to Be Overhauled, San Francisco, Cal.—Oliver Olson has procured the steamers Yolanda, Gabriel and the Ghislaine. The name of the Yolanda, which is the first to arrive, will be changed to Virginia Olson, and has been placed in dry dock for a general overhauling. The other two vessels will have their names changed after they have arrived at San Francisco and will receive a general overhauling as well.

Dredge Reconditioning, Charleston, S. C.—Among the contracts which the Charleston Dry Dock & Machine Company have in hand is the reconditioning of the United States dredge Barnard. Four Scotch marine boilers, built by the company, will be installed, and the vessel's hull and superstructure will be extensively repaired. The superheater installation, which will be by the Superheater Company, is especially interesting, it being the first instance in which superheated steam has been used on a United States dredge. The cost of the work is about $400,000.

New Vessels for Pleasure Resort, Milford, Del.—Burlington Island, New Jersey, is being equipped with an amusement park, fitted with the latest type of pleasure seeking devices, under the management of the Burlington Island Amusement Company, of which Captain L. H. Garrison has charge. It is expected that this will greatly increase passenger traffic to the Island, and increased facilities are being supplied by William E. Doron, who has just placed a contract for a small motor transfer boat with the William G. Abbott Shipbuilding Company for delivery in May, 1922. The Burlington Island Amusement Company is proceeding with arrangements to put in service new and faster vessels between Philadelphia and Burlington Island, which will maintain frequent service between these two points. The marine construction and rebuilding of the vessels for this service is under the supervision of Chapman & Fisher Company, Inc., 524 Walnut street, Philadelphia, Pa.

Towing Dredge, New York.—According to information obtained by Marine Engineering and Shipping Age, the Wah Chang Trading Corporation of China, represented in New York City by Sam Fung, is in the market for designs for a self-propelled steel, bucket, towing dredge to be worked out in America, partly fabricated in this country and erected in China. The boat is to be used as a towing barge as well as a dredge. It is understood the craft is to be 120 feet overall length, 22 feet 6 inches beam, by 8 feet deep, and is to have a compound surface condensing engine with a 13-inch high pressure cylinder, 27-inch low pressure cylinder and 16-inch stroke.

CONSTRUCTION FOR NAVY

Vessels under construction for United States Navy and their degree of completion as reported January 1, 1922, by the Bureau of Construction and Repair, Washington, D. C., are as follows:

Type Number and Name	Contractor	Percent of Completion Jan. 1, 1922
BATTLESHIPS (BB)		
45 Colorado	New York S. B. Corpn.	86.
47 Washington	New York S. B. Corpn.	69.8
48 West Virginia	Newport News S. B. & D. D. Co.	70.
49 South Dakota	New York Navy Yard	38.
50 Indiana	New York Navy Yard	34.3
51 Montana	Mare Island Navy Yard	27.6
52 North Carolina	Norfolk Navy Yard	36.7
53 Iowa	Newport News S. B. & D. D. Co.	31.2
54 Massachusetts	Beth. S. B. Corpn. (Fore River)	11.
BATTLE CRUISERS (CC)		
1 Lexington	Beth. S. B. Corpn. (Fore River)	31.1
2 Constellation	Newport News S. B. & D. D. Co.	20.
3 Saratoga	New York S. B. Corpn.	32.4
4 Ranger	Newport News S. B. & D. D. Co.	3.8
5 Constitution	Philadelphia Navy Yard	12.8
6 United States	Philadelphia Navy Yard	11.8
SCOUT CRUISERS (LIGHT CRUISERS) (CL)		
4 Omaha	Todd D. D. & Const. Corpn.	99.
5 Milwaukee	Todd D. D. & Const. Corpn.	93.6
6 Cincinnati	Todd D. D. & Const. Corpn.	87.6
7 Raleigh	Beth S. B. Corpn. (Fore River)	63.7
8 Detroit	Beth. S. B. Corpn. (Fore River)	76.9
9 Richmond	Wm. Cramp & Sons Co.	83.
10 Concord (a)	Wm. Cramp & Sons Co.	79.
11 Trenton	Wm. Cramp & Sons Co.	55.
12 Marblehead	Wm. Cramp & Sons Co.	47.
13 Memphis	Wm. Cramp & Sons Co.	40.
AUXILIARIES		
Repair Ship No. 1, Medusa (AR1)	Puget Sound Navy Yard	74.1
Dest. Tender No. 3, Dobbin (AD3)	Philadelphia Navy Yard	66.9
Dest. Tender No. 4, Whitney (AD4)	Boston Navy Yard	47.1
Sub. Tender No. 3, Holland (AS3)	Puget Sound Navy Yard	21.5
Aircraft Tender, Wright (AZ1)	Tietjen & Lang	Del. 12/16/21
PATROL VESSELS		
Gunboat No. 22, Tulsa (PG22)	Charleston Navy Yard	71.3
DESTROYERS		
338 Wasmuth	Mare Island Navy Yard	Com. 12/16/21
339 Trever	Mare Island Navy Yard	98.8
340 Perry	Mare Island Navy Yard	86.
341 Decatur	Mare Island Navy Yard	82.1

(a) Light cruiser No. 10 Concord—Launched 12/15/21.

Type Number and Name	Contractor	Percent of Completion Jan. 1, 1922

Fleet Submarines Nos. 166-171.

Neff Submarine (1) No. 108.

Barge Repair, Victoria, B. C.—The contract for repairs to the Canadian Pacific car barge, which was wrecked at Porlier Pass last month, has been awarded to the Victoria Machinery Depot at a price of approximately $50,000. The job will require several weeks for completion.

Extensive Repair Job, Newport News, Va.—The oil tanker F. D. Asche, recently almost a wreck off the Barbadoes, has been taken to the plant of the Newport News Shipbuilding & Dry Dock Company for repairs. The contract cost was figured at $391,000. The tanker, which was built at Newport News, will be reconditioned for the Standard Oil Company.

Seek Passenger Vessel, China.—It is reported that the China Mail Steamship Company has been looking for some time for a suitable passenger vessel to run in conjunction with the steamer Nile on their Hongkong, Straits Settlement and Singapore service. Although a canvass of the various ship markets of the world has been made by the company, no decision has yet been reached as to the selection of a vessel.

Overhaul of Freighters.—It is announced that the Shipping Board has started the overhauling of eight or ten freight steamers in order that they may be ready for sea as soon as possible, as recent inquiries received by the Board indicate that early use will be made of the vessels. The ships range from 6,000 to 9,000 tons, and are of the general cargo type.

Munalbro Contract Award, Brooklyn, N. Y.—Theodore Crane & Son, for a price of $3,900 and six days, has been awarded the contract for repairs to the Munson Line steamship Munalbro, which was recently damaged in a collision with the Crowell & Thurlow schooner W. F. Freeman. The steamer's starboard side and the bow were considerably damaged.

Vessel to Be Converted Into Transport, San Francisco, Cal. — The steamship West Lewark, a freighter which has been turned over to the army transport service of the War Department to replace the Dix, will undergo extensive alterations to fit her for transport service between the ports of Honolulu and San Francisco via Seattle. She has been placed on the dry dock of the Moore Shipbuilding Company, and while there will also be cleaned and painted.

Burner Installation, New York City.—The Peabody Engineering Corporation, 331 Madison avenue, has been awarded the contract for the Peabody-Fisher wide range fuel oil mechanical burners for the tank ship, now in course of construction at the yards of the New York Shipbuilding Corporation, Camden, N. J. The ship is building for the Japanese Imperial Navy, and is to be used for carrying coal as well as oil fuel for navy purposes.

Repair Contracts, Hoboken, N. J.—The steamship Storm King has been awarded to the W. & A. Fletcher Company for dry docking, repairs to hull damage, engines and auxiliaries and various other work. The same shipyard has also been awarded the S. V. Harkness, of the Standard Oil Company of New Jersey, for tank and machinery repairs, and the freighter Clement Smith, of the Calvert Navigation Company for repairs and reconditioning of turbines. The three contracts involve close to $10,000. The steamship Elliott, also of the Standard Oil of New Jersey, is at the Fletcher yard for dry docking and general repairs at a price of $5,700.

To Build Motorships, New York.—Bids for the construction of six combination cargo and passenger Diesel motorships, plans and specifications for which were issued recently by Whittlesey & Whittlesey, 17 Battery Place, New York, were opened on January 20. The ships will be 225 feet in length and will have a speed of 13 knots. These vessels are for the Tri-National Steamship Company, 17 Battery Place, and it is understood a portion of the new fleet will be used on the route between Boston and Halifax.

Steamers Overhauling, San Pedro, Cal.—The steamship Yale, of the Los Angeles Steamship Company, has been placed in dry dock by the Los Angeles Shipbuilding Company to undergo a complete overhauling. When the Yale resumes her run the company flagship, the Harvard, will undergo a similar overhauling.

Lighthouse Vessels, Washington, D. C.—According to the Commissioner of Lighthouses of the Department of Commerce, careful estimates and examinations as to the condition and further serviceability of vessels of the Lighthouse Service, it is found that sixteen light vessels and eleven tenders should be replaced within the next five years. For the construction of new lighthouse vessels, a request for $730,000 is now pending before Congress.

Coast Guard Cutters, Washington, D. C.—The United States Coast Guard is making plans and has asked for an appropriation for the construction of two coast guard cutters, one of 1,200 horsepower and one of 2,400 horsepower. The boats are to be propelled by Diesel electric engines, one to be equipped with four sets of 600 horsepower each, and one to be equipped with two sets of 600 horsepower each.

Dredge, Wash., D. C.—The War Department, it is understood, is preparing plans and specifications for a seagoing dredge 246 feet long, to be equipped with Diesel electric drive of six units of 500 horsepower each, or a total of 3,000 horsepower.

SHIPYARDS AND DRYDOCKS

Shipyard Incorporated, Jacksonville, Fla.—It is announced that the Merrill-Stevens Dry Dock & Repair Company has been incorporated with a capital of $100,000 at Wilmington, Del., to acquire and operate shipyards, dry docks, etc.

Shipyard Addition, Fairfield, Md.—The Union Shipbuilding Company will call for bids in about a month for the construction of a two-story building 70 by 200 feet, to be erected at its plant. Revised plans for the structure are now under way. F. Stauffen is manager.

Yard to Be Dismantled, Bristol, Pa.—It is reported that the Shipping Board, Washington, D. C., will soon commence the dismantling of a portion of the Merchant Shipbuilding Corporation's plant at Bristol, and it is expected that cranes, crane runways and various yard equipment and other machinery will be placed on the market at an early date. The plant will, however, be operated by the Merchant corporation for some time to come.

Dry Dock Charges Reduced, Canada.—In order to be able to meet United States competition, the charges for the use of Canadian dry docks on the Pacific Coast have been reduced about one-third, or back to their pre-war level, for the next six months, at the end of which period the question of dry dock charges will have been considered and definitely settled by the Government. The graving dock at Esquimalt and the floating dry dock at Prince Rupert are affected by this reduction.

Shipyard to Resume Operation, Pensacola, Fla.—It is reported that operations at the plant of the Pensacola Shipbuilding Company will be resumed on a limited scale. At the present time there are under construction at the yard two steel barges and a snag boat, the latter to be shipped to South America. It is proposed to erect the snag boat and then take it down, mark the pieces and ship it to its destination in knockdown fashion.

PORT IMPROVEMENTS

Pier, Etc., Sanford, Fla.—The Chamber of Commerce contemplates the construction of a pier and boat basin. W. T. Donnelly is the marine engineer.

Docks, Tarpon Springs, Fla.—Willis Castaing, Mayor, has let a contract to the J. B. McCrary Engineering Company, Atlanta, Ga., for the construction of a concrete dock at the foot of Tarpon Avenue. This work will involve the expenditure of $236,000.

$900,000 Approved for New Pier, New York.—The Board of Aldermen of the City of New York at its meeting on December 27, 1921, unanimously adopted the report of the Committee on Finance in favor of adopting the ordinance providing for an issue of corporate stock in the amount of $900,000, which is for the removal of present pier No. 32, North River, the construction of new pier No. 32 and dredging of the north side of pier 31, the center of slip between pier 32, as proposed, and present pier 33.

Plans and specifications for the new pier will probably be under way by the Department of Docks early in 1922. The proposed new pier will be 200 feet wide and 1,021 feet long on the north

side, with reinforced concrete piles and foundation for a two-story shed for extra heavy loads on the roof. It is expected that the pier will be fitted with modern equipment which will be handled under a separate contract.

River Landing, Vicksburg, Miss.—The city will vote on $80,000 bonds, to be used for the construction of a river landing.

Deepening Channels, Levees, St. Louis, Mo.—According to Col. Charles L. Potter, president of the Mississippi River Commission, the sum of $6,670,000 will be expended during the year 1922 to deepen channels and protect the levees of the Mississippi River.

Deepening Harbor, Etc., Goderich, Canada.—The Department of Public Works, Ottawa, Can., plans extensive harbor improvements, including the deepening of the harbor at Goderich and improving and making additions to the docks. The cost of the work is estimated at $50,000.

Transit Shed, Tacoma, Wash.—All bids for the construction of a transit shed on the port docks were rejected by the port commission a few days ago, as they were above the $500,000 estimate made by the engineers. The drawing of new plans has been ordered, and bids will again be called for in about six weeks.

Wharf Construction, New Orleans, La.—It is reported that George R. Putnam, Commissioner of Lighthouses, recommends the construction of a wharf at New Orleans for the accommodation of lighthouse tenders. It is estimated that the cost of constructing and equipping the wharf will be $132,750. [illegible]intendent of Lighthouses of the New Orleans district, may be addressed concerning this project.

Dredging, Etc., Jacksonville, Fla.—United States Engineer O'Neil is making a survey of the upper part of the Charlotte harbor with a view to extending the channel to the retaining walls of Great Bridge, and dredging a turning basin between the bridge and the railroad docks at Punta Gorda. Further information may be obtained from the Mayor.

Dock, Hyder, Alaska.—E. J. Williams, who operates vessels on the mail route between Ketchikan and Hyder, Alaska, contemplates the construction of a dock at Hyder. It is stated that Mr. Williams is ready to proceed with the building of the dock, if arrangements can be made for the construction of an approach to it, the approach to be 2,200 feet long and to cost $10,000. The dock will cost about $5,000.

To Build Dock, Noble's Island, N. H.—The Standard Oil Company of New York has made an application to the City of Portsmouth, N. H., and the War Department, requesting permission for the construction of a large dock on property which has been controlled for many years by the Boston and Maine Railroad. The company contemplates making Portsmouth one of its big distribution points and sending its products to this port in large vessels.

New State Pier, Portland, Me.—Preliminary work in connection with the proposed state pier at Portland, Me., has been started. Contract for the removal of old wharves, etc., and dredging of some 150,000 cubic yards of material, involving the expenditure of approximately $70,000, has been awarded to the Aberthaw Construction Company, of Boston. It is expected the work will be completed early in April, at which time the construction of the pier itself will start.

Will Rebuild Pier, Sarasota, Fla.—The city contemplates the rebuilding of their 100-foot pier. For further information address the Mayor.

To Rebuild Wharf, San Diego, Cal.—It is reported that the Spreckles Brothers Commercial Company, San Diego, who handle the coaling for the entire port of San Diego, contemplate the redecking and remodeling of their coal bunkering wharf, the work to involve the expenditure of about $40,000.

Pier Construction, Portland, Maine.—According to the latest report, it is practically settled that the Port of Portland Commission will during this year construct Pier No. 3 at Municipal Terminal No. 4, this pier to be used temporarily as an open pier without transit shed. The new pier will be 1,500 feet in length and about 240 feet wide.

Crane Contract Award, Stapleton, S. I.—The Wellman-Seaver-Morgan Company, Cleveland, Ohio, has been awarded the contract for supplying mechanical equipment for the new Staten Island piers 12 and 13. The contract, known as contract A, amounts to $324,500, and calls for a large number of cranes of the most modern type.

Dredging, Jacksonville, Fla.—John Emmille was awarded the contract for dredging the harbor of Brunswick, Ga.

Seawall, Bay St. Louis, Miss.—The city contemplates the construction of a seawall to cost $100,000. Further information may be obtained by addressing the Mayor.

Pier, St. Petersburg, Fla.—It is reported that the Atlantic Coast Line Railroad will rebuild its pier at the foot of First avenue. W. H. Willoughby, Wilmington, N. C., is chief engineer for the company.

Dock, Canal, Etc., Hartford, Conn.—Plans have been prepared by the Water Commissioners of Hartford, Conn., for the South Meadows project, involving the building of docks, canals, a drainage system, etc. Fay, Spofford & Thorndike, 15 Beacon street, Boston, Mass., are the engineers.

To Improve Harbor, Louisiana.—A survey is being conducted by the Lake Charles Association of Commerce for perfecting the Calcasieu Parish Deeper Waterway Project and creating a port for Southwest Louisiana. A Federal appropriation of $780,000 is available for this work, and Parish will supplement the Government aid by a bond issue of $1,500,000.

Harbor Improvement, Cork, Ireland.—The Harbor Commissioners, Cork, Ireland, reported at a meeting held a short time ago that they had decided to secure the services of the American engineer, Mr. Nicholson, who is advisory engineer to the Port of Seattle, to advise on the improvement scheme in Cork harbor, on which £1,000,000 is to be expended.

Pier, Philadelphia, Pa.—A contract for the construction of piers for the bridge connecting Philadelphia and Camden, N. J., has been awarded to the Keystone State Construction Company of Philadelphia, Pa., and the firm of Holbrook, Cabot & Rollins, of Boston, by the joint Delaware River Commission. The bid, made jointly by the two firms, amounted to $1,669,775. Work on these piers will probably be commenced on January 6.

GOVERNMENT WORK

The following specifications are available at or in contemplation by the Bureau of Yards and Docks, Navy Department, Washington, D. C., for various work on material as listed below:

Power Plant Equipment, Bellevue, D. C.—Bids are being received for 150 horse-power return tubular boilers and mechanical stokers, boiler and fire pumps, motor-driven air compressor or brick setting and superheaters for four boilers, crane, two turbine-driven forced draft fans, air condenser and circulating pumps, pipes, etc., to be furnished and installed. Specification 4497.

Reservoirs and Dispensary, Yorktown, Va.—Construction at mine depot planned. Specification 4565.

Storage Buildings, Pearl Harbor, T. H.—Mine storage building at the ammunition depot planned. Specification 4567; and five buildings for torpedo and ammunition storage at the same depot; Specification 4566.

Motor Generator Set, Hampton Roads, Va.—Installation of motor generator set and switchboard at the naval operating base planned. Specification 4570.

Steam Piping System, Yorktown, Va.—Installation planned. Specification 4573.

Operating and Power Building, Etc., Tatoosh, Wash.—Operating and power building with accessories at the naval radio station contemplated. Specification 4574.

Dredging, Norfolk, Va.—A contract for dredging 200,000 cubic feet in order to deepen the waterfront of the Navy Yard at Norfolk has been let to the Jones Dredging Company, Norfolk.

Storehouse, Pearl Harbor, T. H.—Specification 4504. The Bureau of Yards and Docks, Navy Department, Washington, D. C., has awarded a contract to W. F. Martens, 53 Franklin Street, Rochester, N. Y., for the construction of a one-story storehouse, the price being $196,775. Two hundred and sixty-three days will be required for the completion of the work.

Dredging, Los Angeles, Cal.—The District Engineer has awarded a contract to the United Dredging Company, Central Building, for dredging in Los Angeles harbor, the work to cost $37,340.

Dredging Plant, San Diego, Cal.—The United States Engineer has awarded a contract to the Olympian Dredging Company, 249 First avenue, San Francisco, Cal., for the hire and operation of a dredging plant at a price of $125,000.

NEW INCORPORATIONS

The Empire Steamship Company, Manhattan, has been incorporated, with a capital of $50,000, by F. Leftwich, J. L. Smith and L. Dunkelman. F. Weinstein, 165 Broadway, New York, is attorney.

The Commercial Pilot Steamship Company, Ltd., has been incorporated in Wilmington, Del., with a capital of $100,000, to build, own and operate boats.

The Inter-Coastal Steamship Company has been incorporated in Dover, Del., with a capital of $1,000,000, to engage in ocean commerce.

The Arconstruct-Hullfin Engineering Company has been incorporated with a capital of $100,000 under the laws of Delaware to carry on the business of naval architecture and marine engineering, operating under exclusive Arconstruct-Hullfin combination patent rights held by C. V. S. Wyckoff, naval architect and consulting engineer. The officers of the new company are as follows: C. V. S. Wyckoff, president; F. F. Boyd, vice-president; Frank Nichols, vice-president; Morgan Olcott, secretary, and Robert B. Palmer, Jr., treasurer.

The Terminal Iron Works Co. has been organized by Harry W. Fawke, of San Francisco, former superintendent of hull construction at the Moore Shipbuilding plant, and Edward McKarley, of Stockton, who have acquired the plant and property of the Stockton Iron Works for the manufacture of steel and iron products. The company is considering the establishment of a branch plant for ship repair work, to be operated in conjunction with their structural department.

FOREIGN ACTIVITIES

New Port, Rocky Point, Mex.—A new port terminal is being constructed by the Tucson, Gila Bend and New Cornelia Railroad at Rocky Point on St. George's Bay, Gulf of California, on the mainland about 100 miles north of Guaymas. The company proposes in this way to provide an outlet for the products of the Arizona copper mines.

Provisional Wharf.—The Mexican Government is reported to have approved plans and considerable materials have been ordered for the construction of a provisional wharf at Manzanillo. The new wharf will be about 450 feet long and 45 feet wide, with a draft alongside of not less than 30 feet.

Wharf Construction.—It is announced from Guayaquil that the recent Congress of Ecuador has authorized the letting of contracts for the construction of a wharf and custom house at Guayaquil in connection with other projects. Funds for the port construction are to be provided in part, either at public auction of Government owned land in Guayaquil or by loans secured by these lands.

New Harbor, Gisborne.—The Marine Department of New Zealand Government has approved and adopted the plans prepared for the proposed harbor at Gisborne.

Site for Port, Komarno, Poland.—The Czecho-Slovak Government has acquired a site at a price of half a million kroner at the town of Komarno on the Danube for the purpose of establishing a port.

Shipbuilding, Germany.—According to the American Bureau of Shipping, German shipyards turned out about 400,000 gross tons of ships in 1921. One hundred steel ships, ranging in size from 1,500 to 10,000 tons, are included in this figure. Of these 100 vessels six were motorships aggregating 30,284 gross tons. German shipbuilding now ranks second to that of Great Britain.

BUSINESS NOTES

William Homes Davis, president of the Virginia Forwarding Corporation is the new president of the Hampton Roads Foreign Trade Club.

B. C. Colonna, of the Colonna Marine Railway Corporation, is the new president of the Norfolk Ironmasters' Association, an organization of ship repair plants.

The Bird-Archer Company has moved its New York office from 90 West street to 33 Rector street.

Messrs. Rossell and Thayer, naval architects and marine engineers, Forrest Building, Philadelphia, Pa., have been made the sales engineers and exclusive agents of the Superior Iron Works Company of Superior, Wis., for the territory from Portland, Maine, to Norfolk, Va. They handle steam and electric deck machinery and steering gears and special dredging machinery, as well as a patented steam scow winding gear.

The twenty-fifth annual meeting of the American Society for Testing Materials will be held on June 26-July 1, 1922, at Atlantic City, N. J., with headquarters at Chalfonte-Haddon Hall Hotel.

O. M. Rau, formerly consulting engineer to the Philadelphia Rapid Transit Company, has become associated with the Hardinge Company, Inc., 120 Broadway, New York, and will specialize in the handling of Quigley Pulverized Fuel Systems as applied to boilers. W. O. Rankin has also become associated with the Hardinge Company, in the capacity of managing engineer of the Quigley Pulverized Fuel Department. These changes have taken place with the acquirement by the Hardinge Company, Inc., of the Pulverized Fuel Department of the Quigley Furnace Specialties Company.

William Thompson, district manager for the Texas Company has been elected president of the Hampton Roads Maritime Exchange for the year 1922.

The Pneumercator Company, Inc., announces the removal of its factory from Philadelphia, Pa., to the Sperry Building, 40 Flatbush Avenue Extension, Brooklyn, N. Y., on February 1. Its general offices at 15 Park Row, New York, will be located at the new factory after February 1.

George W. Green has resigned as assistant general manager of the Los Angeles Steamship Company, San Francisco, Cal., to become general assistant to A. J. Frey. He formerly was Mr. Frey's assistant in the Pacific Mail construction division of the Shipping Board and Los Angeles Steamship Company.

TRADE PUBLICATIONS

Soot Blowers in Marine Boilers.—The Diamond Power Specialty Company, Detroit, Mich., has recently published an enlarged and revised edition of bulletin 134, "How Some Ship Owners Have Increased their Profits." This book deals with soot losses in coal and oil fired boilers, with a special section devoted to the latter type. In addition, the bulletin describes and illustrates in detail the automatic rear end front operated soot blower for double and single ended Scotch boilers, the front end oscillating type, the revolving type for water-tube boilers, the Diamond system for hollow staybolts in horizontal baffled water-tube boilers. This bulletin may be obtained from the Detroit or New York offices of the company.

Centrifugal Pumps.—An instruction book dealing with the construction and installation of centrifugal pumps of the VH type, class B, BS and OS has been issued by the Worthington Pump & Machinery Corporation, N. Y. Actually this might be termed a hand book on centrifugal pumps for the use of operating engineers. Complete details for the erection of pumps are given in the first part of the book, followed by curves showing the maximum water temperature allowable for different suction lifts. Farther along curves are given of the head capacity and efficiency capacity characteristics of the centrifugal pump. The various types of pumps are described in detail and many useful tables of data given. Readers may obtain copies of the book from the company by asking for bulletin No. 605-L.

Machine Tools.—The "Triplex" No. 1 machine tool designed for turning and boring, milling, thread cutting and drilling is described in detail and its application to each of these operations in a pamphlet sent out by the Triplex Machine Tool Corporation, New York. The advantage of this machine is that it combines a number of machine tools in one, cutting down equipment investment and saving floor space. A price list is included in the pamphlet.

"Bridging Two Oceans and Linking Four Continents" is the title of a booklet, recently issued by the Canadian Pacific Railway, which contains descriptions of the company's steamship services and various facilities offered. It tells of the company's ocean tonnage of 800 growing into over 465,000 tons, and the one service into numerous ones by which Canada is now linked with four continents. Illustrations and descriptions of the more pretentious vessels, including the *Empress of Canada*, a vessel of 22,500 tons, *Empress of Australia*, etc., are given, as well as illustrations of the various ports in all countries of the world which are linked by the Canadian Pacific services. Special mention is made of their oil-burning vessels and their particular advantages.

"Old Ironsides"—A decorative calendar carrying a history and reproduction of a painting of the famous frigate *Constitution* is being distributed by the Columbian Rope Company, Auburn, N. Y. A bulletin describing the complete process of the manufacture of Columbian pure manila, tape marked rope is also available. The company will be pleased to send these on request.

Requests for change of address should reach us two weeks before the date of the issue with which it is to go into effect. It is difficult, and often impossible, to supply back numbers to replace those undelivered through failure to send advance notice. In sending us change of address, please be sure to send us your old address as well as the new one.

The President's Message

THE President's long-expected message was delivered before a joint session of the two Houses of Congress on February 28. As predicted in the February issue of this magazine, the President recommended a direct subsidy to all ships engaged in foreign commerce amounting to a maximum of about $30,000,000 per annum or in the neighborhood of 10 percent of the anticipated revenue from customs.

In addition to a subsidy, he recommended several forms of indirect aids which should be highly constructive without being a drain upon the public treasury. The message contains over 4,000 words, and it is an able and convincing plea for the same sort of protection for shipping that is given to our other industries. The President's plan is as follows:

"What, then, is our problem? I bring to you the suggestions which have resulted from a comprehensive study which are recommended to me by every member of the United States Shipping Board. It is a program of direct and indirect aid to shipping to be conducted by private enterprise. It is proposed to apply generally the benefits which it was designed to derive from discriminating duties to all ships engaged in foreign commerce, with such limitation on remuneration as will challenge every charge of promoting special interests at public cost.

"In lieu of discriminating duties on imports brought to us in American bottoms it is proposed to take 10 percent of all duties collected on imports brought to us in American or foreign bottoms, and create therefrom a merchant marine fund. To this fund shall be added the tonnage charges, taxes and fees imposed on vessels entering the ports of continental United States, also such sums as are payable to American vessels by the Post Office Department for the transportation by water of foreign mails, parcel posts excepted.

"Out of this fund shall be paid the direct aid in the development and maintenance of an American merchant marine. The compensation shall be based on one-half of 1 cent for each gross ton of any vessel, regardless of speed, for each 100 miles traveled. When the speed is 13 knots or over, but less than 14, two-tenths of a cent on each gross ton shall be added; for 14 knots, three-tenths of a cent; for 15 knots, four-tenths of a cent; for 16 knots, five-tenths; for 17 knots, seven-tenths; for 18 knots, nine-tenths; for 19 knots, eleven-tenths; for 20 knots, thirteen-tenths shall be added to the basic rate. For 23 knots the maximum is reached at 2.6 cents for each gross ton per 100 miles traveled.

"I will not attempt the details of requirements, or limitations, save to say that all vessels thus remunerated shall carry the United States mails, except parcel post, free of cost, and that all such remuneration must end whenever the owner of any vessel or vessels shall have derived a net operating income in excess of 10 percent per annum upon his actual investment, and thereafter the owner shall pay 50 percent of such excess earnings to the merchant marine fund, until the full amount of subsidy previously received is returned to its source. In other words, it is proposed to encourage the shipping in foreign trade until the enterprise may earn 10 percent on actual investment, whereupon the direct aid extended is to cease and the amount advanced is to be returned out of a division with the Government of profits in excess of that 10 percent. The provision makes impossible the enrichment of any special interest at public expense, puts an end to the Government assumption of all losses, and leaves to private enterprise the prospective profits of successful management.

"Of the indirect aids there are many, practically all without draft upon the public treasury, and yet all highly helpful in promoting American shipping.

"It is a simple thing—seemingly it ought not require the action of Congress—but American officials traveling on Government missions at Government expense ought to travel on American ships, assuming that they afford suitable accommodations. If they do not afford the requisite accommo-

dation on the main routes of world travel, the argument that we should upbuild is strongly emphasized.

"I think we should discontinue, so far as practical, the transport services in the Army and Navy, and make our merchant and passenger ships the agents of service in peace as well as war.

"We should make insurance available at no greater cost than is afforded the ships under competing flags, and we can and will make effective the spirit of section 28 of the Jones Act of 1920, providing for preferential rail and steamship rates on through shipments on American vessels. American railways must be brought into cooperation with American steamship lines. It is not in accord with either security or sound business practice to have our railways furthering the interests of foreign shipping lines, when the concord of American activities makes for common American good fortune.

"Contemplating the competition to be met, there ought to be an amendment to the interstate commerce act which will permit railway systems to own and operate steamship lines engaged in other than coastwise trade. There is measureless advantage in the longer shipments where rail and water transportation are coordinated, not alone in the service but in the solicitation of cargoes which ever attends an expanding commerce.

"We may further extend our long-established protection to our coastwise trade, which is quite in harmony with the policy of most maritime powers. There is authority now to include the Philippines in our coastwise trade, and we need only the establishment of proper facilities to justify the inclusion of our commerce with the islands in our coastwise provisions. The freedom of our continental markets is well worth such a favoring policy to American ships, whenever the facilities are suited to meet all requirements.

"Other indirect aids will be found in the requirement that immigration shall join wherever it is found to be practical in aiding the merchant marine of our flag under which citizenship is to be sought, and in the establishment of the merchant-marine naval reserve. The remission of a proportion of income taxes is wholly compatible when the shipping enterprise is of direct Government concern, provided that such remission is actually applied to the cost of new ship construction.

"Congress has already provided for a loan fund to encourage construction. It might well be made applicable to some special requirements in reconditioning.

"It is also worth our consideration that, in view of suspended naval construction, the continued building of merchant ships is the one guaranty of a maintained shipbuilding industry, without which no nation may hope to hold a high place in the world of commerce or be assured of adequate defense.

"A very effective indirect aid, a substitute for a discriminating duty which shall inure to the benefit of the American shipper will be found in the proposed deduction on incomes, amounting to five percentum of the freight paid on cargoes carried in American bottoms. The benefits can have no geographical restrictions, and it offers its advantages to American exporters as well as those who engage in import trade."

The Great Lakes-St. Lawrence Waterway

JUDGING from editorial comment in the newspapers of the interior, the proposed Great Lakes-St. Lawrence waterway has considerable support in at least eighteen of the middle-western states. President Harding endorsed the project in a speech before the National Farm Conference on January 23 and it has since been announced that Secretary Hughes has been directed to negotiate a treaty with Great Britain under which the United States and Canada can jointly undertake the building of a shipway from the lakes through the St. Lawrence river to the Atlantic. Representative Mapes of Michigan has introduced a bill in Congress authorizing the President to spend $100,000 to defray the expenses of the American members of an international commission to work out the plans for a thirty-foot channel and for the development of water power.

If this proposed waterway is constructed, the water power that it can develop will be its real justification; for the cost of construction and maintenance of a canal must be considered in the total cost of transportation over a waterway just as the cost and maintenance of a road bed must be added to the price of transportation of a railroad. It is certain that shipping could defray neither the cost nor the maintenance of this project because the saving that is possible in avoiding a transfer of cargo at the seaboard would be largely offset by the extra time that a ship would lose in making its way at a reduced speed through the locks and narrow channels of such a long waterway. However, as a power project, it might be a good investment and on this subject some interesting figures are given.

Col. W. P. Wooten, Corps of Engineers, U. S. A., and W. A. Bowden, chief engineer, Department of Railways and Canals, Canada, who were appointed by their respective governments to investigate the possibilities of this improvement, report that $252,728,200 will be necessary for the complete improvement for navigation purposes and the development of approximately 1,464,000 horsepower delivered at the switchboard. Mr. Paul T. Brady of the Westinghouse Electric and Manufacturing Company figures that the 1,464,000 horsepower, which is equivalent to about 1,100,000 kilowatts, would deliver in 7,000 of the 8,760 hours in a year 7,700,000,000 kilowatt hours to sell. He estimates the fixed charges, maintenance and amortization charge to pay the debt in fifty years at $13,049,232 per annum, which, if taxes are eliminated, would make the cost of a kilowatt hour something less than 2 mills.

To distribute this power over a 300-mile radius, it is estimated that $75,000,000 additional would have to be spent for transmission lines and towers and that this cost would have to be financed by private interests. Assuming $9,000,000 as a fair charge per annum to take care of the interest, depreciation, operation, maintenance and amortization of the $75,000,000, the cost of the power would be about 3½ mills per kilowatt hour as compared with 1 cent per kilowatt hour that it costs New York today to generate power from coal.

If the above figures are approximately correct, and the project is completed, it appears that the lake seaports would

be presented with an outlet to the ocean which would undoubtedly have a stimulating effect on shipping and the industrial development of the interior. The people of the Middle West are not apt to feel the vital interest which they should in an adequate merchant marine, notwithstanding the fact that American shipping is just as important to the welfare of those states as it is to the seaboard. The construction of this waterway might do much to bridge the gap in the shipping perspective now existing between the seaports and the interior.

A Brighter Outlook

THE month of February marked a definite improvement in the shipping and shipbuilding situation. Numerous inquiries for the chartering and building of passenger ships were current in January but, outside of a few reconditioning jobs, such as the *Manchuria, Mongolia* and *Ruth Alexander* (ex-*Callao*), nothing of importance had actually developed. It is common knowledge that a thorough search has been made for passenger tonnage, and it has been found that vessels of this class ready for service under the American flag are not to be obtained in the market.

The first contract for the year for the construction of two new passenger vessels was awarded to the Wilmington plant of the Pusey and Jones Company early in February. These vessels, which are to be 330 feet long, 58 feet beam and of 2,750 gross tonnage, are for the Seaboard Bay Line. Each ship will have 175 staterooms and special bedrooms, all of which will be fitted with the most up-to-date improvements.

The big event of the month was the awarding of the contract to recondition the *Leviathan* to the Newport News Shipbuilding and Dry Dock Company. This is the greatest single step that the new Shipping Board has made toward placing our merchant marine on an equal basis with our foreign competitors. It is highly significant, indicating, as it does, that the board is confident that Congress will support the shipping legislation that is to be recommended by the President and that the appropriations requested by the board will be granted.

Another thing, it is apparent that, although the *Leviathan* will be second to none as a passenger liner when completed, she will require two other ships to work in combination with her. Two such ships of express speed are available, the *Agamemnon* and *Mount Vernon*. Both of them can be reconditioned in eight months' time at a total cost of less than the sum that will be spent on the *Leviathan*. The present indications of heavy passenger travel during the season of 1922 show that good use can be made of these vessels.

The passage of subsidy legislation will undoubtedly release several orders. The American Bureau of Shipping reports that there are substantial inquiries for at least a dozen sea-going ships, most of which are passenger vessels, and that there is a decided shortage of this type of craft in the United States. While inquiries are not necessarily contracts, yet, when the Bureau uses the term "substantial inquiries" it undoubtedly means that the contract plans of these proposed ships have been submitted to the Bureau for advice and suggestions relating to future classification.

The Shipping Board at the time of this writing has placed 46 idle ships in commission since January 1, and it is reported that it contemplates allocating 40 more in the near future. A number of these have been chartered on the bare boat plan, thus assuring the board of a profit rather than a loss on their operation.

Another forward step is the betterments now under way on the State ships allocated to the United States Lines. The *Lone Star State* and the *Peninsula State* when completed will carry first and third class passengers only. These ships should be highly successful as their third class accommodations are the equal in location and quality to the second class accommodation on other liners, while the first class accommodations are better than can be obtained elsewhere for the same price.

The *Centennial State, Old North State* and *Panhandle State* are being converted to cabin ships carrying one class only. By placing a convertible upper and lower berth in each stateroom, thus berthing four instead of two per room, it will be possible to halve the price of the passage. These ships will certainly appeal to persons in moderate circumstances and will no doubt make it possible for many to travel who otherwise would not.

Advertising American Passenger Liners

IN view of the attacks that have been recently made in Congress against the Shipping Board policy of advertising American passenger ships, we are inclined to wonder whether the destructive criticism that certain newspapers—notably the important dailies of New York City—have directed against any attempt to build up an American merchant marine along the lines successfully adopted by our foreign competitors is not having a most decided and injurious effect upon some of our legislators.

The notorious fact that a number of our patriotic public officials travel on foreign passenger liners every chance they get ought to be a sufficient reason to any fair minded Congressman that the general public, who are not supposed to be so well informed on matters affecting the general welfare of the nation, should be advised through high class advertising of their own passenger ship services. If public officials prefer foreign ships, it is all the more important to direct the attention of the traveling public to the fact that they own a number of high class safe and comfortable ships themselves and that the Shipping Board, through some of the best known steamship lines, is operating these ships for their own benefit.

We don't want to hog all the commerce for American ships, either freight or passenger, but we do want a fair share. Government statistics show that approximately 250,000 Americans travel by sea from the United States every year. Suppose one-half or 125,000 of these travelers attempted to patronize their own ships, what would be the consequence? Nothing less than that the shipyards of this country would be busy creating new tonnage. The allied trades would be working overtime furnishing equipment and fittings for the best ships that the world has ever seen. Yes, and of far more importance than this, our present naval strength in desirable convertible merchant tonnage would begin to assume something like a proportion to the 5-5-3 naval ratio that our statesmen have made the general public believe indicates the comparative strength of our Navy.

The Navy Yards Are for the Navy

We have just witnessed a very narrow escape from a serious injury to our merchant marine. Although most everyone knows that the recent reduction in our naval strength makes an efficient merchant marine doubly important, yet we have seen a determined attempt by the politicians of Massachusetts to deliberately hold up the reconditioning of the *Leviathan* in the hope that the Boston Navy Yard might obtain this work through a questionable estimate.

That a bid from a navy yard is no more nor less than an estimate is evident from the following quotations from a letter written by Edwin Denby, Secretary of the Navy, to the *New York American* under date of November 8, 1921:

"A bid by a private firm is a guaranty of the performance of the work at a price named and within a time stipulated.

"A bid from a navy yard is the estimated cost of the work. If work is awarded a navy yard after an estimate, the actual cost of the work is charged, whether the same be greater than or less than the estimated cost. Estimates ordinarily run fairly close, say, within about 10 percent; but in a big reconditioning job where the actual amount of work necessary can only be revealed after opening up work and uncovering all defects, it is difficult to make an estimate that will fall within 10 percent of the actual cost.

"Furthermore, the stipulated time for performance of work for other departments of the Government must always be subject to the condition that urgent naval work shall take precedence even if such precedence causes failure to perform the other Government departments' work within the time stipulated.

"As the total cost of reconditioning the *Leviathan* will probably run somewhere between $6,000,000 and $8,000,000, it will be seen that an estimate submitted by a navy yard would not give the Shipping Board the exact information which they desire as to cost and time of performance of this work. The necessity for economy is so great that the authorities of the Shipping Board do not feel that they could take the chance of overrunning the estimated cost by possibly $500,000 or $600,000. They must have a guaranteed total expenditure."

The Secretary of the Navy might have gone even farther than this; he might have added that the Merchant Marine Act both in spirit and in letter directs the Shipping Board to get the Government out of the shipping business; he might have added that such work in a navy yard does not include overhead charges on the plant investment or insurance which must come out of the taxpayers' pockets and he might have added that the organization of a navy yard, while excellent for naval work, is not nearly so well adapted for merchant work.

It is true that it has been the practice of the navy yards to charge a certain overhead on private work, including most everything except plant investment and insurance, but labor organizations interested in navy yard work backed by the American Federation of Labor, have demanded that other than naval work be given to the navy yards in order to allow the continued employment of the men and that all overhead charges arising from the military functions of these establishments, as well as those arising from equipment made idle by past failure to keep it in production, be eliminated in figuring the costs.

It seems, therefore, that, in spite of the fact that there should be as many men employed whether a ship is repaired at a navy yard or a private plant, an effort is to be made to urge legislation to keep the Government in the shipping game. It is of vital importance to encourage private capital to invest in shipping and shipbuilding, but this will be a hopeless task if the Government, backed by the public treasury, is to compete against it.

We want an adequate American merchant marine and an efficient American Navy. To accomplish this, we must have shipyards and navy yards, but we must remember that ships are not built so that shipyards may have work nor are warships constructed so that navy yards may repair them. As the general welfare of our shipyards must depend on the success of the merchant marine so must the amount of work available for navy yards depend on the size of the navy. Special jobs in the navy yards can only hope to delay the final day of adjustment at the expense of the shipyards and the taxpayers. The navy yards are for the Navy and they should so remain.

The Naval Morale

They have served up the Navy on a silver platter as a sacrifice on the altar of Peace but no murmur of complaint has been made by the naval officers who have been trained to submit as well as to command. Our Navy with its splendid tradition has no finer example of the self restraint of its entire personnel than has been given during the last few months while the fate of its latest and most powerful ships has hung in the balance.

It is only human to consider selfish interests and these men have known full well that this great reduction in warships means far fewer opportunities for promotion. Yet they have not complained because they also have known that the continuation of the competitive building of armament means ruin and disaster to the world.

However, the stopping of competitive building does not mean that we are not to have a Navy that is reasonable in size. By the terms of the treaty we will still have 18 battleships, 316 destroyers, 35 cruisers, 147 submarines, 196 auxiliaries and 152 small vessels. In addition to this, a number of scout cruisers and aeroplane carriers will be added as the treaty provides for them. This is the size of a navy that the Disarmament Conference considered necessary to meet the minimum requirements for the safety of the United States.

To return to our subject, is the naval personnel which has been reduced to 6,129 commissioned officers and 96,300 enlisted men to be subjected to wholesale slaughter or are the ships that we are allowed to retain to be efficiently manned? If Congress is not satisfied with the drastic cut that has already been made and decides to lay up the remainder of the fleet or keep it in an undermanned condition, then an unjustified strain will be placed on the morale of the Navy which would amount to nothing less than criminal negligence in the present state of world civilization.

Why We Should Have a Subsidy

By "Old Scotch"

The greatest question before the American shipping public is still the proposal to devise some means whereby we can operate our immense merchant fleet, in being, successfully. All other questions are subordinated until we find the solution of how our American ships can be kept on the seas.

At this writing, early in February, the President has not made his expected visit to Congress for the purpose of addressing them on the subject of aids to the merchant marine, but there seems no doubt but that he will do so in the near future. The several committees of experts have made their reports on the various phases of the subject and everybody interested is ready for the initiative to be taken.

The enemies of the measure have started in to oppose it and are evidently paving the way for a vigorous campaign against it. Already editorials have appeared in certain daily newspapers opposing whatever form the proposed legislation may take. These "patriotic" effusions are so uniformly opposed to anything beneficial to the American merchant marine, that it is really quite amusing to observe the various lame excuses given for opposing this particular class of proposed legislation. To bolster up their views (probably made abroad) they have their various correspondents interview certain gentlemen who are opposed to anything in which they are not personally interested and quote at length their opinions as the voice of the people rising up in indignation against this approaching legislation to aid shipping, whatever it may be. In other words, they do not know anything about the subject, nor do they know what form of relief is to be asked for, but on general principles they are "agin" it.

Nevertheless and notwithstanding, some measure of relief for shipping is bound to pass and at this session of Congress, too. The reasons for such relief are so impelling, and will be presented so forcefully, that any of our national legislators who are not violently and unreasonably prejudiced can and probably will support it. There are so many viewpoints which can be taken on the whys and wherefores of this proposed legislation that regardless of party affiliations or local interests any member of the House or Senate can find it to the advantage of his constituency to support the measure.

Merchant Shipping a Means of National Defense

Let us consider it for this article solely as a matter of national defense—all parts of the country are vitally interested from that standpoint. The Limitation of Armaments Conference, now so happily terminated, has, by its agreement to limit the number of capital ships, made merchant shipping of double the importance that it was before. With a limited number of battleships, every large passenger or freight vessel becomes potentially a national asset for purposes of defense. While we are all in more or less accord as to the advisability of reducing competitive armaments, there are but few of us sufficiently idealistic and optimistic to think that all wars are over. Far from it, and particularly will we find it fallacious, if we do not from now on maintain a robust American merchant marine. With our war vessels reduced to the agreed minimum, if we allow our merchant vessels to disappear from the seas, we will be as helpless as a one-arm man in a street brawl, and the brawlers will know that the one-arm man has large sums of money in his pockets.

No matter in what form future warfare may develop, whether on land, on sea, or in the air, merchant shipping must necessarily be a vital element for the transportation of troops, supplies and munitions of whatever kind may be used. Even if this country is not directly involved, the warfare may be between countries upon whom, unless we keep up our own shipping, we have been forced to depend for ocean transportation. We only have to harken back to 1914 and 1915 to understand how such a condition may well arise and what serious consequences it could bring upon our whole business interests.

Notwithstanding the many beneficial international agreements entered into at the recent conference, we must not forget that the use of the submarine was very slightly curbed. Should we maintain but a very small merchant marine, a few energetic enemy "subs" could very quickly put it out of business.

Merchant Marine Naval Reserve Proposed

One proposal of combining our naval resources with our merchant fleet has already been made, and it is well worthy of the attention of our law makers. Briefly, the plan is that instead of cutting down our existing naval personnel, by summarily discharging about one-third of the commissioned officers and enlisted men, as is now being seriously considered by Congress, in order to reduce maintenance expenditures proportionate to the reduction in capital ships, it is proposed that they be placed in what would be termed a Merchant Marine Naval Reserve.

The proposal is to pay these officers and men half of their present naval salaries from appropriations for the national defense, providing they serve on merchant vessels and receive the other half of their pay from the shipowners or operators. This would accomplish a saving of about twenty-five millions of dollars in the annual naval appropriation and would make it unnecessary for Congress to appropriate money as a subsidy fund to shipowners, in order to overcome the differential between American wage rates and the wage rates of our competitors. This, it is estimated, would cost for an adequate American merchant marine, about twenty-five millions of dollars. The Government would by such a procedure save fifty millions of dollars annually and would not have lost any of its effective fighting strength, so far as trained naval personnel is concerned.

As the Navy must operate the merchant marine in time of war, it would by this method have a splendid trained personnel to operate merchant vessels in a very efficient manner, and thus avoid many of the sad experiences which we had during the past war. Some of our merchant crews during that period were composed of the worst bunch of foreign highbinders and bolshevists ever gathered together since the days of Captain Kidd and his "regular" pirates. The surest way, therefore, to make our merchant crews thoroughly American, with innate ideas of discipline and loyalty to our flag, is to adopt some such method as this.

Of course there would have to be limitations on the use of these young naval officers, as the transition from purely war duties to merchant duties could not be made over night. It has therefore been proposed that only naval officers who

are under thirty years of age be taken over, and that with the understanding that they be placed under trained merchant skippers, chief engineers and first mates for a period of five years, until "they know the value of a dollar and how to make it instead of spend it," as one well known shipping man recently expressed it.

One Hundred Percent American Crews

The merchant marine would be the gainer by injecting such an element of selected and well trained youngsters in it to replace all aliens. Of course no one would think of displacing that fine array of genuine Americans who have in the past five or six years taken up a seafaring life, but they unfortunately are not sufficient in number to man a real American merchant marine of the proper size to meet our demands both for trade and for national defense. With the addition of the naval contingent we would, in a few years, have a trained personnel in our merchant marine which would be second to none in the world, as it would then be truly "one hundred percent American."

As many of us can well remember, it was only as recently as the Spanish war when the Navy staff was manned by a heterogeneous collection of enlisted men almost of 57 varieties. One ship, and a flagship at that, which the writer knows of in particular, actually had representatives of 26 different nationalities in her crew of 350 men. One wag (American, of course) suggested that a sign "English spoken here" be posted on the berth deck. Now the Navy, according to the latest reports, is composed of over 99 percent American citizens, and its efficiency is as nearly perfect as it can be made. If reductions must be made in this well-trained force of men, what better place to put them than on our merchant vessels?

Our Merchant Marine Created for Commerce and National Defense

We must not forget, in this connection, that the Jones bill committed this country to a policy of maintaining a merchant marine adequate to its needs both for commerce and national defense. The necessity for our merchant marine to develop and maintain our commerce overseas has been plainly demonstrated by many able statesmen and writers. Not so much has been written as to its value and absolute necessity for our national defense and it has been the endeavor in this brief dissertation to point out some of the salient features along these lines.

Viewed as a strictly business proposition, there are some well meaning economists who might satisfy themselves that to subsidize or give preferential treatment to merchant shipping, as such, is not based on their ideas of logic. Unfortunately there are quite a number of followers of such theories who do not have the breadth of vision to see that a nation's shipping must not be weighed in the scales of economic suppositions. To any such, let them adopt their theories as they may on that ground, but in the light of past history (which is always the best precursor of what may happen in the future) let them not forget that the merchant marine must be maintained as an element of national defense, and a more important element at this time than ever before.

It has been clearly demonstrated that we cannot operate merchant ships in competition with our rivals, for the plain reason that our standards of wages and living are the highest in the world, and we just don't want to lower them for any part of our people, until we are compelled to do so. We find that we can overcome this difference in expense by the Government contributing from thirty to fifty millions a year to private shipping enterprise. It is necessary for our national safety that we keep up our merchant shipping, so let us pay out this money and not call it a SUBSIDY—call it a national defense fund, but make it available just as soon as possible, before we slip back to our pre-war state of unpreparedness.

Water-Borne Commerce Shows Marked Upward Trend

THE water-borne foreign trade of the United States showed marked improvement for the month of December, according to figures given out by the Shipping Board. Excluding bulk oil moved in tankers, the total overseas traffic increased 609,500 tons, or 21 percent over the November figures. Exports alone showed an increase of 32 percent. This is the first upward trend in our shipping figures since the coal movement in June.

The Shipping Board maintains statistics of the waterborne foreign trade of the United States measured in long tons weight and divided under three heads, the over-seas cargo movement, the bulk oil movement in tankers, and the Great Lakes movement.

The total imports decreased 9 percent and the total exports increased 12 percent compared with the previous month, but if compared with the same month in the previous year, there is shown a 6 percent loss in imports and a 40 percent loss in exports, or a total decrease in the year of 26 percent, or 2,400,000 tons.

The Great Lakes traffic, with the closing of the season, declined about 48 percent, from 1,409,190 tons in November, to 730,639 tons in December. November, with the influx of Canadian grain, marked the peak of the import movement, while August shows the peak of an export movement which included, during the year, more than two million tons of American grain. December imports were 610,456 tons, 37 percent less than November, and exports were 120,183 tons, 72 percent less than November. American vessels carried 96 percent of the imports, 70 percent of the exports and 92 percent of the total cargo tonnage.

Tanker cargoes in December aggregated 2,397,988 tons, an increase of 4 percent over November. Imports were 1,883,316 tons, two thousand and sixty-five tons less than November, and exports were 514,672 tons greater, an increase of nearly 22 percent over November. American vessels carried 86 percent of the imports, 34 percent of the exports and 75 percent of the total tanker cargo tonnage.

The important portion of our foreign commerce, that carried in overseas cargo vessels, increased from 2,900,000 tons in November to 3,500,000 tons in December, and marks the first gain in our overseas commerce since the flurry of May and June caused by the miners' strike in England. Further, this gain was entirely in the exports, as the imports fell off slightly. The total export overseas, exclusive of oil, amounted to 2,521,132 tons, or an increase of 32 percent over the previous month, although still 45 percent less than the export trade of the same month a year ago. Including both exports and imports, our overseas dry cargo trade in December was 21 percent above the previous month and 41 percent less than that of December, 1920. In this trade American ships carried 27 percent of the exports, 34 percent of the imports, and 29 percent of the total trade.

Handling of the George Washington Appreciated

APPRECIATION of the efficient and capable manner in which the *George Washington,* operated by the United States Lines for the Shipping Board, was handled on her recent trip from New York to Bremen during several days of one of the most severe storms that has ever been experienced on the North Atlantic Ocean is contained in resolutions received by the Shipping Board, signed by Alexander P. Moore, owner of the *Pittsburgh Leader;* Robert Goelet, Henry Kaufmann, Adolph Vogel and J. M. H. Lidgerwood.

The Shipping Subsidies of Japan and France

By Winthrop L. Marvin*

Two nations besides Great Britain—Japan and France—have made long and extensive use of shipping subsidies for the encouragement of their merchant marines. Postal subventions, general subsidies and even shipbuilding bounties have been practiced by these two countries for many years. How have they succeeded?

JAPAN was chiefly a nation of junks when in 1896, after her victorious war with China, she began to give vigorous national aid to her shipbuilding and navigation. There were then, it is true, a few Japanese ocean steamers, but they aggregated only a little over 100,000 gross tons—five years before the Chinese war produced its sudden need of transports, Japan had only thirteen ocean steamers of 27,700 gross tons. The war had brought an impressive object lesson to the Island Empire, and it had resolved never to be a shipless land again.

The Japanese government in 1896 frankly modeled its shipping acts on both British and French precedents. To its national ocean mail lines Japan, exactly as Great Britain had been doing since 1839, gave generous direct subsidies or subventions, and not content with this and realizing that it was not sufficient, Japan also provided bounties for the encouragement of shipbuilding and mileage subsidies for general shipping, exactly as France had done.

Shipbuilding in Japan was then a small, precarious industry. Most of the Japanese ocean vessels had been bought from Europe. The first Japanese shipbuilding bounty law, enacted in 1896 to be effective for fifteen years, gave 20 yen (about $10) per gross ton for the construction in Japan of seagoing ships of more than 1,000 tons gross register, and in addition a bounty of 5 yen ($2.50) for each indicated horsepower of machinery. Under this encouragement ocean steamers of increasing size began to be constructed, and Japan developed the excellent shipyards which for many years since have been producing not only her merchant vessels but her men-of-war.

Navigation Bounties for All Ocean-going Vessels

General navigation bounties based on French policy were provided in the acts of 1896 for all ocean-going vessels of the Japanese merchant marine—the rate being at so much per gross ton per hundred miles run, as in original French practice. For the further encouragement of native shipbuilding foreign-built vessels, except the very latest, not more than five years of age, were excluded from the benefits of these navigation subsidies.

In addition the Japanese government subsidized very liberally new regular passenger, mail and fast freight steamship services to Puget Sound, San Francisco and Australia, another line to Europe and subsequently a line to South America. This policy gave to Japan within a few years an excellent fleet of thoroughgoing liners and cargo steamers, and at the same time created highly efficient construction yards and an adequate force of naval architects, engineers and workmen. When Japan suddenly attacked Russia in 1904, the Japanese government was abundantly supplied with transports and auxiliary vessels to supplement its navy, and also reserve officers and men of the merchant service and admirable facilities for the reconditioning and repair of its battleships and cruisers. As a means of quickly providing a great merchant marine, invaluable in peace or war, the Japanese subsidy policy had proved wonderfully successful. Appropriations for this policy in the Imperial budget for the year ending March 31, 1909, included the following in yen (yen equals 50 cents):

	Yen
Shipbuilding bounties	1,995,400
Navigation bounties	3,483,955
Subsidy to European line	2,673,895
Subsidy to San Francisco line	1,013,880
Subsidy to Seattle line	654,030
Subsidy to Australian line	425,782
Subsidies to various lines to Korea, Dalny, China, and other Asiatic and domestic ports	2,118,713
Total	12,365,655

Subsidies Constantly Maintained

That is to say, in 1909 the Japanese government was expending upwards of $6,000,000 in subsidies and bounties for the encouragement of its shipbuilding and navigation—or about five times the total ocean mail disbursement of the United States. On one line of three ships to San Francisco in 1910 Japan was expending $1,340,000—in fact, making up its commercial deficit and sustaining three admirable ships of its naval reserve which could not possibly have lived without it. These three Japanese steamers, by the way, were at that time the fastest and most formidable auxiliary cruisers on the Pacific Ocean.

As Japan's merchant marine has steadily developed through the years, there have been changes in the details of legislation, but the principle of national aid by subsidy has been constantly maintained. After a considerable fleet of cargo steamers had been created, the navigation bounties to ships of this type were gradually discontinued, and the ships were left to rely on their low wage costs of operation. Japanese shipbuilding bounties are still in force, though suspended during the world war for the time being. The national steamship services like those to Europe and to the Pacific coast of the United States are still in receipt of subsidies that rank among the highest in the world. Here are the records of the marvelous growth of the Japanese merchant marine under a policy similar to that recommended for the American Congress:

Year	Tons
1895	301,101
1900	574,557
1905	873,552
1910	1,149,222
1914	1,708,386
1915	1,826,068
1916	1,847,453
1919	2,325,266
1920	2,995,878
1921	3,354,806

What subsidy has done for the Japanese merchant marine is one of the most significant events of history. With no such ocean-going traditions and no such commercial experience as the Americans, the Japanese before 1914 had far

*Vice-president and general manager of the American Steamship Owners' Association, New York.

outstripped us in the development of a modern overseas merchant fleet—because theirs had been a protected industry while ours had not been.

France, from whom Japan took her shipbuilding bounties and navigation subsidies, has made a long, brave effort to evolve a merchant shipping of high character. Originally, many years ago, France pursued a free ship policy of depending for her tonnage on ships from foreign yards. This free ship experiment, of course, proved to be a dismal failure, paralyzing French shipyards without adding any substantial new tonnage to the merchant marine. In fact, for years the entire French shipping amounted to only about 1,000,000 tons, coastwise and overseas tonnage both included.

French Adopt Subsidy Principle in 1881

In 1881 the French people, chagrined at long failure, resolved upon the adoption of a comprehensive system of construction and navigation bounties, and more liberal postal subsidies than had been paid before. In their zeal the French included sail vessels within the benefits of the law and at first provided a bounty for them that was actually more generous and effective than aid given to steamers. A larger subsidy to sail vessels than to steam craft was a manifest economic blunder which developed a beautiful sail fleet but did not symmetrically increase the merchant marine. The French subsidy law of 1881, amended in 1883, was still further amended in 1902 and again in 1906.

French subsidy and bounty laws, so frequently altered, have gradually become more efficient and productive. The French budget for 1908 provided 10,400,000 francs ($2,700,200) for shipbuilding bounties and 31,500,000 francs ($6,079,500) for general navigation and shipowners' subsidies. French shipping was in a relatively flourishing condition and gained markedly in tonnage, just before the outbreak of the great world war.

The backbone of the modern French mercantile marine consists of the two great postal steamship companies, the Compagnie Générale Transatlantique and the Messageries Maritimes. These are among the oldest and most famous of the overseas steamship companies of the world, and have been very liberally supported throughout the years by the French government and people. It is in the fleets of these two great companies that French maritime achievement is seen to the best advantage—great, fast steamers, admirably officered and manned. In 1909 the French government was paying a total amount of $13,423,737 in encouragement to its merchant marine, of which somewhat more than $5,000,000 was devoted to the postal subsidies.

Now Third Largest Shipping Nation

Those who speak of the French subsidy system as a failure are unaware of the real facts. There have been many defects of detail in French subsidy laws in the past, but these have gradually been eliminated and the French policy of national aid has proved more and more notably successful. There can be no gainsaying the official records of the recent growth of the French mercantile marine which from 1890 on are as follows:

Year	Tons
1890	1,045,102
1895	1,094,752
1900	1,350,562
1905	1,728,038
1910	1,882,280
1914	2,319,438
1915	2,285,728
1916	2,216,643
1919	2,233,631
1920	3,245,194
1921	3,652,249

Here are actual figures which speak far more eloquently than any irresponsible anti-subsidy propaganda. From a negligible factor in 1890, France has steadily advanced until she stands at present as one of the three greatest merchant shipping powers of the world—her tonnage in 1921 exceeding Japan's and placing her next only to Great Britain and the United States of America. Norway, with all her traditional talent for shipbuilding and navigation, has not of recent years succeeded in increasing her merchant tonnage as notably as has France, the Norwegian merchant marine in 1921 standing at 2,584,058 tons gross register, more than a million tons below the total of France. Of course, both France and Norway suffered terribly from the ravages of the German submarines.

Foreigners Fear an American Subsidy

Most of the assertions which we have been accustomed to hear in the United States, that the French subsidy policy was not productive, refer to the earlier and experimental period of French legislation. Those who have implicitly accepted these statements from overseas have simply fallen victims to interested propaganda. Foreigners who have marked well the amazing development of manufactures under a protective policy in the United States, live in mortal dread of the application of a protective policy to American shipbuilding and navigation. They are appalled at the prospect that such a policy in a few years might make the United States the greatest shipbuilding and navigating power in the world. Hence the publication and distribution of a vast library of misinformation on the subject, to muddle the minds of the American people.

The frequent assertion that France has spent millions in subsidy, with only the result that her merchant marine is as little as ever, is an example of the truth and accuracy of this kind of propagandist literature. Of course, it is a lie out of whole cloth, but it is astonishing how many American public men and editors have allowed themselves to be deceived by it without making any investigation of their own.

Both Japan and France have conspicuously succeeded in their shipping subsidy undertakings—Japan the more quickly and easily because she is an island empire, with a redundant population, rapidly developing her own industries and commerce. Indeed, her government has made the encouragement of shipping its chief, dominant thought for the past twenty years, while to France the development of her merchant marine has been an important, but not an all-pervading, thought. Yet of the two France is today the greater maritime power, measured by the tonnage of her merchant fleet.

Neither Japan nor France begins to have the resources of the United States for the creation and maintenance of an immense merchant trading tonnage. Our commerce is incomparably greater. So are our ports and seacoasts, our resources for shipbuilding, our historic fame for skilful navigation. Let us not forget that within the memory of many men now living our chief competitor, Britain, frankly acclaimed our shipowners, officers and seamen as the most efficient and successful men of their calling in the world. That was in the years when there was something like fair play for the American merchant flag on the long routes of ocean commerce. That fair play there has not been for a decade preceding, and almost six decades following, the Civil War.

Model Marine Insurance Law for District of Columbia Passed by House and Senate

Consideration of the bill providing for a model marine insurance law for the District of Columbia was begun in the House on February 13 and continued on February 15, when it was set aside for other business. The bill was passed by the House on February 22. It had previously been passed by the Senate.

Congress and Shipping Board Have Begun to Act

Leviathan Contract Awarded at Last—Shipping Board Appropriation Assured—Entire Government Fleet Offered for Sale

By Harold F. Lane

THE contract for the reconditioning of the *Leviathan* was awarded, at a special meeting of the Shipping Board on February 15, to the Newport News Shipbuilding and Dry Dock Company, Newport News, Va., in spite of a vigorous campaign on the part of labor organizations, Massachusetts Congressmen and others to force the board to have the work done at the Boston Navy Yard.

The board stated that the approximate cost of placing the giant liner in commission would be $8,200,000. Of this amount $5,595,000 will be spent for general reconditioning and conversion of the vessel into an oil burner and $515,000 for repairs to machinery. Both of these contracts were awarded to the Newport News Shipbuilding and Dry Dock Company. Gimbel Brothers of New York were awarded the contract for the equipment of the steward's department and for a library, the price being $551,000.

Gibbs Brothers, engineers, of New York, were retained by the board to supervise the reconditioning of the ship, their fee being $182,000. William Francis Gibbs of this firm was formerly chief engineer in charge of construction for the International Mercantile Marine Company of New York but severed his connection with that corporation to join with his brother, Frank H. Gibbs, in forming a new company to supervise the work. They will employ a staff of assistants. In awarding this contract the board made a saving of $28,000 as the International Mercantile Marine Company was to receive the sum of $210,000 according to the terms of a contract it had with the board. This contract was recently cancelled by mutual consent.

The balance of the $8,200,000, namely $1,357,000 will be expended for moving the ship to the contractor's yard, insurance covering this removal, new anchors and chains, moving the vessel to dry dock, dry docking, trial trip, and maintenance and guarding of the ship for 14 months during reconditioning.

Work to Start Immediately

Work on the *Leviathan* will be started immediately and she will proceed at once under her own steam to the shipyard at Newport News. The contract was signed by Joseph W. Powell, president of the United States Shipping Board Emergency Fleet Corporation, and Homer Ferguson, president of the Newport News Shipbuilding and Dry Dock Company.

As soon as she has been reconditioned at the Virginia plant the *Leviathan* will be taken to the Boston Navy Yard where she will be dry-docked and her bottom scraped and painted.

At the time bids were asked for—last November—on this vessel the Secretary of the Navy stated that his department did not have an appropriation to prepare an estimate, did not have the facilities to carry out this type of work and could not submit a bid upon which a binding contract could be made. For these reasons the Navy did not figure on the work. Secretary Denby reaffirmed his position in a conference with Chairman Lasker of the Shipping Board on February 14.

The board issued a statement saying it was obliged to award the contract to the Newport News Shipbuilding and Dry Dock Company because:

1. February 15 had been fixed months ago as the last day when the bids put in by the competing contractors would remain open.

2. The bids were taken at the low dip of the market and undoubtedly if new bids were taken again a considerable increase in the estimates, probably more than a million dollars, would result.

3. If the matter were put over until the Navy could submit an estimate, which it has informed the board is not desirable or practicable, it would take that department at least 60 days in which to prepare an estimate, as it occupied that period of time for the successful contractor at a cost of $30,000 to make up its proposal. If the Navy therefore was to bid on this work now, it would mean the loss of the Spring and Summer trade in 1923, which in money would amount to more than a million dollars, which in addition to increased costs would greatly raise the total.

4. The Newport News Shipbuilding and Dry Dock Company were the lowest bidders.

The President, Chairman Wesley L. Jones of the Senate committee and Chairman William S. Greene of the House committee on merchant marine affairs have approved the action of the Shipping Board in awarding the contract to the Virginia corporation.

Yard Ready to Start Work

The Newport News Shipbuilding and Dry Dock Company, which recently reduced its forces, expects to take on 1,500 to 2,000 additional men to handle the *Leviathan* work, making a total of about 5,000. The company, in anticipation of the contract, started dredging a place alongside one of its piers early in February for the *Leviathan* to berth. Schedules for new fittings and equipment amounting to over $1,000,000 that are necessary for reconditioning the vessel have been prepared.

The necessity for making complete new plans and specifications directly from the ship, which was done at a cost of $250,000 after the Germans had demanded $1,000,000 for the plans, has made it possible to get a lump sum bid for the work, the first time on a reconditioning job of this magnitude, it is said. Usually work of this kind involves a large sum for extras, but because of the completeness of the specifications it was possible to get eight lump sum bids. Officials of the board consider that the expenditure of $250,000 on the plans will, therefore, save perhaps $2,000,000 in the total cost of doing the work.

The highest possible standards are to be adopted in the reconditioning. Entirely new electric lighting, heating and plumbing systems are to be installed and it is believed that the safety will be greatly increased by the plans for eliminating one-half of the watertight doors below the waterline.

All first-class cabins are to be equipped with telephones and it is expected that by the time the ship is ready for service in May, 1923, the art of wireless telephony will have made such advances that it will be possible to send and receive messages from the cabins to and from any part of the world. Chairman Lasker says the boat will be "the finest hotel in the world on land or sea."

Boston Navy Yard Wanted the Contract

Much pressure was brought to bear on the Shipping Board and the President to have the work done at Boston, particularly since the reductions in force that were made at the various navy yards, but the President has been adhering to the policy of "less government in business" and

moreover he took the position that the work would relieve just as much unemployment in one community as in another. The Mayor of Boston had been in Washington trying to influence the giving of the work to the Charlestown navy yard, the Massachusetts legislature had sent a memorial to Congress, the labor unions had been most active, and Representative Dallinger of Massachusetts had succeeded in securing the adoption by the House of an amendment to the appropriation bill for the Shipping Board and the Fleet Corporation which would require giving the navy yard an opportunity to estimate on the work. Senator Lodge of Massachusetts made an effort to have a similar amendment added in the Senate, but after he had failed to win support for it he accepted a substitute suggested by Senator Jones of Washington which contained the words "unless the President shall otherwise direct." The President had previously placed himself on record as opposed to giving the work to a navy yard in a letter to the Massachusetts Congressman who had asked that the work be given to the Boston yard.

With this amendment the bill was passed by the Senate on February 11, but as the bill still had to go to conference it was obvious that it could not become a law by February 15. The labor organizations had organized a lobbying committee of 30 members the night before, with President Samuel Gompers of the American Federation of Labor at its head, and each member called on three senators to urge them to vote for the "Lodge amendment." The modification suggested by Senator Jones enabled a good many of them to comply, who might otherwise not have done so. It was then impossible for the Shipping Board officials to say that they had any clear mandate from Congress, as it was obvious that the bill could not be passed by February 15, and they had previously indicated that in the absence of an expression by Congress the full responsibility would be upon the board for getting the work done in the most economical way.

I. M. M. Releases Board From Contract

Shortly before the announcement of the award the fact was made public that the International Mercantile Marine Company had reluctantly, at the urgent request of the Shipping Board, released the board from an option or contract entered into with former Chairman Payne, under which it was to supervise the reconditioning and later operate the ship. The board took the position that there was no binding contract but at its request the company agreed to waive the claim.

Shipping Board Appropriation Assured

The bill carrying the appropriations asked by the Shipping Board and the Emergency Fleet Corporation has been passed by both the House and the Senate without reduction of the amount, with various provisions restricting the expenditure of the funds which were included in amendments adopted by the House but not by the Senate, which required that the bill be sent to conference. The appropriation for the Fleet Corporation for the fiscal year 1923 as provided in the bill is $50,000,000 for operations and $50,000,000 for the settlement of claims, of which $30,000,000 is to be immediately available. A provision in the bill to make available the balance not used by July 1 of the $55,000,000 which under the previous appropriation bill may be used by the board out of the proceeds of the liquidation of assets was struck out on a point of order in the House but was left in in the Senate bill.

The appropriation for the Shipping Board proper is $459,000, including $20,000 for the investigation of foreign discrimination against vessels and shippers of the United States and for the investigation of transportation of immigrants in vessels of the Shipping Board.

Debate Brings Out Criticisms

In the House there was much debate and criticism of the board because of the salaries paid to officers and other transactions, but in the Senate the debate was principally on the question of the reconditioning of the *Leviathan*.

The House amendment proposed by Representative Dallinger of Massachusetts provided that no part of the appropriation shall be expended for the "purchase, acquirement, repair, or reconditioning of any vessel, commodity, article or thing," which at the time can be manufactured, produced, repaired or reconditioned for a less cost in any United States Government navy yard or arsenal, provided that this limitation shall only apply to vessels while in the harbors of the United States and all expenditures in connection with such work are to be considered in estimating the cost." An amendment proposed by Representative Graham of Illinois that not more than $1,000,000 shall be spent for the repair, reconditioning or rebuilding of any one ship was rejected after a long debate.

The bill as reported by the House committee provided that not more than 13 officers or employees, including seven attorneys, should be paid a salary in excess of $11,000. The last appropriation bill limited this number to six and the purpose of the bill was to allow the payment of $11,000 to seven attorneys. After a long debate, an amendment proposed by Representative Byrns of Tennessee was adopted, limiting the number of salaries in excess of $11,000 to six as at present and striking out the provision for seven attorneys. In the Senate, however, the committee proposal was adopted. An amendment limiting to $350,000 the amount to be expended as compensation for attorneys, regular or special, proposed by Representative Jones of Texas, was rejected in the House, as was one proposed by Representative Davis of Tennessee to reduce the appropriation for claims to $25,000,000 instead of $50,000,000.

Among the amendments adopted by the House was one by Representative Walsh of Massachusetts limiting the salaries to be paid by the board to $25,000 a year. A similar proposal was rejected, however, by the Senate. Another, proposed by Representative Black of Texas, provides that no claim shall be paid out of the amount provided unless the Shipping Board shall find that such claim grew out of an agreement, express or implied, entered into with the board or the Emergency Fleet Corporation or their legal representatives.

Publicity and Advertising Matter

An amendment proposed by Representative Walsh, which was adopted, provides that no part of the funds appropriated shall be expended "for the preparation, printing, publication or distribution of any bulletin, newspaper, magazine, journal or other periodical, or for services in connection therewith, not including, however, the preparation and printing of documents and reports authorized or required to be issued by law." This was struck out in the Senate.

An amendment proposed by Representative Byrnes of South Carolina to limit the expenditures for advertising to $500,000 a year was rejected after considerable debate, by a vote of 49 to 45.

Board Offers to Sell Entire Fleet

The United States Shipping Board, through the Emergency Fleet Corporation, has announced its intention of asking bids for the purchase of any or all of its steel cargo vessels, steel passenger and cargo vessels, steel tankers and the other vessels comprising its entire fleet, bids to be submitted by March 14. The ships are to be advertised for sale so that it will be possible to sell any of them promptly, if any offer is made, although it is expected that the best market will not be developed for the ships until the prospects for ship subsidy legislation are known more definitely. Purchasers who are willing to take a "gamble" on the prospect of a subsidy, however, it is said, will probably be able to purchase ships now at a better price than they could get by waiting.

The Fuel Question

By Robert E. Annin

In actual steamship operation the most expensive single item of cost is fuel; and toward economy in this regard there is a continuous struggle. The cheapness with which coal has been produced in the United Kingdom has been perhaps the largest factor in England's commercial supremacy, giving cheap fuel for her factories, cheap bunkers for her ships, a needed bulk export commodity to balance her inward traffic and a commanding control over the world's bunkering stations. Previous to the war Great Britain and her dependencies provided about 65 *percent of the bunker coal used and controlled about* 80 *percent of the bunkering stations. Today, however, through the regular processes of economic selection, oil has won the premier position as fuel for ship propulsion and in this article its advantages are discussed.*

IN fuel for sea-propulsion economy is possible in three directions. First there is the choice of the ship, which must be made in view of size and speed, as well as the nature of the service; the former choice depending largely upon the type of hull, engines and boilers. There follows the question of the *kind* of fuel to be used—coal or oil; and the *quality* of the fuel is of prime importance; for both vary in their thermal efficiency or power producing qualities (per unit of weight) according to their degree of conformation to certain established standards. Again comes the question of fuel *management* which is the responsibility of the engine department. The economical or wasteful use of fuel is a vital point in the records of the engine room.

Beyond this is the prevention of crooked practices by which the ship is overcharged for bunkers; or fuel is dishonestly removed from the ship and sold through collusion between the engine room and the shore—practices often covered up by doctoring the daily records of consumption. Such procedure applies also to provisions and other stores; and points another direction in which the selected personnel of a regular service gives a great advantage to established lines.

As to the choice between coal and oil for steam production at sea, the developments of the past few years seem conclusive wherever conditions approach equality.

Oil Versus Coal

In a preceding article, reference was made to the large proportion of oil-burning ships constructed in English yards during the year ending June 30 last. According to Lloyds, this amounted to 58 percent of the total deep sea tonnage built, and at that did not include ships converted from coal to oil during the same period. Considering the comparatively recent advent of oil as a power producer, so rapid a stride to a commanding position, against such an entrenched rival as coal, must be considered as closely approaching a demonstration of superior efficiency.

Ever since the use of steam began to be recognized as a substitute for animal energy, industrialism has been a constant, and progressive struggle for the economical production and application of power. The steam engine long preceded Watt. As early as 1698 Savery produced an engine for pumping mines, which worked, but was not a real success owing to its enormous fuel cost. Watt (1763) separated the condenser from the cylinder, thus conserving temperature in the latter, greatly reducing fuel cost; and so lifting the steam engine out of the experimental stage.

From then until the beginning of the present century coal was King. But with the discovery of certain grades of mineral oil in the southwestern portion of the United States, in Mexico, and the Malay Archipelago, a new fuel, more economical in production, transportation and application, became commercially available. Oil, by its success as a cheap power producer, has in the interim achieved such a position that it is difficult to see how it is to be displaced. Whether used for production of steam, or in internal combustion engines, no effective competition is in sight, unless vast progress shall be made in the transportation and storage of electrical energy produced by water power.

For reasons which are not far to seek, in every industry where conditions have been approximately even fuel oil has steadily won its way. Compared with coal its efficiency is about three to two—that is two tons of oil will produce the same energy as three tons of coal. There are claims that a result of two to one has been attained, which is possibly true under ideal conditions of oil use. For locomotive use an English railway claimed a test result of slightly better than two to one. Impartial judgment, however, must regard the former comparison as a safer working basis. Hence on a basis of first cost it would appear that whenever the price per ton of coal is two-thirds of the price of oil the first cost of the power unit will be the same whichever fuel is used.

Special Advantages of Oil Fuel

But oil has special advantages beyond its thermal efficiency. It is more easily and cheaply produced, loaded, unloaded and transported. It is practically self feeding, while coal must be painfully and expensively "stoked." It leaves no ashes or clinkers which must be re-handled and disposed of. All these are vital factors entering into fuel cost.

For land uses, such as railways and factories the result has been a progressive displacement of coal by oil wherever the point of consumption was not too far removed from the source of oil supply. Previous to the war, and under a regime of low ocean freights, even Great Britain, with no native oil and with her abundant and cheaply worked coal, was perceptibly swinging toward the use of fuel oil. In that period two large English railways—the Great Eastern, and the London, Brighton and South Coast—installed oil burning apparatus on their locomotives; the advantage, even over coal produced at their own doors, being then decisive. With the swift advance, not only in first cost but especially in ocean freights which followed, conditions compelled a return to coal until a more normal relation between the two should be established. But wherever fuel oil is available its commercial progress as a power producer has been steady and continuous.

For sea use the advantages of oil are accentuated by two considerations which cannot apply (at least, in equal degree) to railways or factories. The latter must, within certain narrow limits, stand the waste of bringing fuel from the source of supply to point of demand. The deep-sea steamer owing to her mobility can and does save a large portion of this waste. Her fuel expense is an enormous proportion of operating cost and she will bunker where bunkering is cheapest.

With the spread of oil stations over the maritime map, and the growth of cheap transport in tankers the advantage

to the lines which have terminals near any oil fields, or to tramps which accept business all over the world, is obvious. They can obtain at a minimum cost that which constitutes their most expensive single item of operation; and can often bunker "for the round" with double advantage.

Gain in Cargo Carrying Capacity

This suggests a second special advantage which steamers find in the use of this class of fuel. If a vessel of 6,000 tons capacity uses 1,500 of this for fuel and stores, she has 4,500 tons capacity left for revenue producing cargo. But if she uses but 1,100 tons for fuel and stores, her potential revenue capacity is increased by 400 tons. Further, apart from dead-weight lift, coal will occupy a space of about 42 cubic feet per ton, which otherwise would be available for cargo; while oil can be placed in ballast tanks (or double bottoms) where it will utilize room which would otherwise be wasted, and leave a corresponding space for stowage of cargo.

Clearly this decision as to oil or coal must regard two main factors.

1. The relative costs per ton, of each, *"under the boiler."*
2. The revenue value of space and lift capacity released by the smaller bulk and weight of the oil.

The latter of course will vary with prevailing rates and market conditions. If cargo is so scarce that full capacity cannot be utilized, this factor may not influence the calculation. Otherwise it must, and frequently does, prove decisive when the price of oil is greatly higher than that of coal.

Reduction in Personnel and Betterment of Working Conditions

Again, the reduction in *personnel* which oil permits is not only important as reducing expense for pay and subsistence but should be welcomed as doing away with that imitation of perdition, the old-fashioned stoke hole. None who have not seen it can have any conception of its horrors; and probably no one can appreciate the suffering which it causes unless he has had personal experience. From the humanitarian point of view alone, therefore, the steady trend toward oil fuel is a subject for congratulation. Anything that tends to lighten the lot of the merchant sailor (none too bright at best) should be welcomed.

To return to the commercial side. It is far cheaper and cleaner to put oil into tanks through a pipe than to load and trim coal into bunkers by dumping and shovelling. The saving of a steamer's time also is of great importance and constitutes an important economy in itself. For bunkering at sea (as in the case of warships, or for relief of a vessel short of fuel) there is no comparison. Coaling at sea is impossible except under favorable conditions owing to obvious dangers. But sea transfer of oil has been easily and safely accomplished through flexible tubes in quite heavy weather.

Costs of Coal and Oil Compared

If a comparison be made as to relative expense of coal and oil on any given ship the compelling reasons which give preference to the latter can be seen at a glance.

If a cargo ship can make a given voyage complete in forty days on 1,500 tons of coal, or 1,000 tons of oil, carrying a cargo of grain at 25 cents per 100 pounds, her expense of fuel and stoking would be about as follows, (with oil 50 percent above coal in price):

Coal

Cost—1,500 tons coal @ $5.00 per ton......	$7,500.00
Wages and subsistence, 9 stokers, 40 days @ $1.85 per day	666.00
Loss in gross revenue, 1,500 tons @ $5.60...	8,400.00
	$16,566.00

Oil

1,000 tons oil @ $7.50 per ton	$7,500.00
Wages and subsistence, 3 fire tenders, 40 days @ $1.85	222.00
Loss in gross revenue 1,000 tons @ $5.60 per ton	5,600.00
	$13,322.00

Here is a direct saving of over $3,200, or say $80 per day. Counting 300 days as the steamer's active year, the direct gain would be $24,000, without counting the saving in bunkering and gain in turn-around.

This is a simple comparison for a small cargo steamer and the saving, while material, will not compare in amount with larger and swifter freighters, to say nothing of large express passenger liners. So far as the latter are concerned oil seems on the point of monopolizing the field; new construction running almost entirely to oil, while coal burners already in service are being rapidly converted.

Savings Effected on the Olympic As An Oil Burner

The latest of these, concerning which details are available, is the White Star steamer *Olympic,* the largest British built passenger ship afloat.

The daily coal consumption of the *Olympic* was about 900 tons. Of oil she burns 600 tons per day, making a saving of say 2,000 tons on her eastward voyage, or 4,000 tons on a round trip.

As a coal burner the *Olympic* carried 246 firemen, working under almost intolerable conditions. Under oil, 60 men attend to the burners under healthy and comfortable conditions. This means economy in human lives. Stokers under the old system were constantly collapsing, frequently under physician's care, and as a class were driven to dissipation, and often to suicide, in the vain effort to forget their miseries.

As to expense, the wages and subsistence of 186 men (say $4,000 on an 18-day round trip) are eliminated—an annual saving (counting 300 days' service) of about $70,000—even under the English scale and with sterling at a discount. But this is not all. The *Olympic* required about 9,600 hours' labor for coaling, and everything had to give place to this vital operation. At that it took between four and five days. She can now oil in eight hours with the labor of ten men, (80 hours' labor) without dust or dirt, and without interfering with any other work. It is merely a matter of pumping from a barge to the ship's tanks. The ship's tanks carry about 7,500 tons and, owing to reduction in quantity and compactness of stowage, the space saved is released for uses producing or directly tributary to revenue.

Economies Compel Use of Oil on Liners

All in all it is obvious that the new liners are being equipped with oil apparatus, and that old ones are being rapidly converted because the resultant economies are simply compelling. Even British owners, who have no home supply of oil and enormous supplies of cheap coal, realize that they cannot meet oil competition with coal. Among the large liners converted to oil are (in addition to the *Olympic*) the *Aquitania, Mauretania* and *Berengaria* of the Cunard Line; and, of new express passenger steamers now building, it is said that practically all are designed for oil. The *Scythia* and *Caledonia* are examples.

It therefore appears that oil has won the premier position through the regular processes of economic selection.

So much for the steamer, on which the test between the two fuels has been chiefly made. When, and if, the internal combustion engine shall supplant the steam engine for sea propulsion (a condition which appears probable) oil seems likely to hold the entire field. For the internal combustion engine can beat the oil burning steamer as badly as the latter has beaten her coal burning rival.

The innate conservatism of the trade has made it cautious in accepting the motorship as a proved success but the results of continuous demonstration must ere long be generally conceded. The motorship appears to loom up as the ocean vehicle of the future.

Growing Importance of the Motorship

It is not necessary to go into more figures. It is enough to say that the motorship, by using about one-third the quantity of oil, can achieve the same speed as an oil burning steamer of equal size. Without going fully into details of various well established records the history of a Swedish motorship (the *Stureholm*) may be quoted.

The ship is of 7,800 tons deadweight capacity and when bunkered for 10,000 miles has a net cargo capacity of 7,200 tons—600 tons only being occupied by fuel and stores. Three consecutive voyages showed an average speed of just under ten knots on a daily consumption of fuel oil of 10¼ tons. An oil burning steamer of the same capacity and speed would be doing well to get off with 35 tons of oil per diem, and her cargo capacity would be reduced, not by 600 tons but by at least 1,700 tons, to take care of fuel and stores.

Not that the internal combustion engine has yet reached a point of development where the road lies straight and clear before it. Expense of original installation, weight, excessive pressures and temperatures are all handicaps at the present stage; and the success thus far has been achieved in spite of these drawbacks.

Sir Owen Phillips (himself an owner of motorships) expresses the belief that the internal combustion engine, as we know it today, will not eventually prove able to hold the field; but that engineers will evolve something giving double the power for half the weight and size.

Economy in the Use of Oil Imperative

That the utmost economy in the use of the world's oil supply is imperative is the gospel preached by all whose opinions on this point are entitled to consideration.

Considering its constantly widening use for power and light and the fact that as a lubricant there is no substitute for mineral oil, estimates that the world's supply can last only thirty to fifty years are disquieting. But this is a far cry. The need of saving every dollar on operation is an immediate and imperative need of the shipowner of today. Fuel is his greatest and most important item. Therefore the important point for the moment is this.

In view of the demonstrated economy of oil as an ocean fuel, coal can hardly come back to its old supremacy until, and unless, the price difference in its favor shall be sufficient to offset the superior economy and efficiency of its rival. This condition may arise whenever from reduction of supply or increase of demand the first cost of oil shall be raised to a point which shall neutralize its advantages in other respects. No such situation is now in sight.

Supremacy of Oil Not Menaced

Fuel oil is really a by-product in the production of gasolene, naphtha, benzine and the other products which utilize the more volatile elements of the crude. With the immense increase of demand for these, the production of fuel oil must continue at a high rate under present conditions, even though steamers are lying idle in every great port of every maritime nation. The United States Shipping Board (for instance) is said to have about a thousand steamers laid up; while the Clyde and Forth are lined with dead tonnage.

As long as this continues oil is likely to be an even fiercer competitor of coal than in the past. With continued production and slack demand the prospects are for continued low and even lower prices.

For a present comparison, good bunker coal is now quoted at 32/6 per ton (say $7.15) at Dartmouth, England. At Hampton Roads the price is about $4.75, plus trimming in (say 30 cents per ton). At New York similar quality is obtainable at about $5.50, to which the cost of trimming must be added (say 60 cents) making the cost (trimmed in) $6.10 per ton.

At this level (New York) fuel oil at $9.00 per ton would involve no larger original outlay than coal, and all the incidental savings would be net. In view of the latter (and varying of course with the individual ship as well as other conditions) oil would have to go to 2½ to 3 times the per ton cost of coal before these advantages would be neutralized.

Should the present situation persist, it would not be surprising if the per ton price of fuel oil should crowd down much nearer to the price of coal than it has ever been before. The inevitable result on the fuel question is too obvious to require comment.

Shipping Board Seeks Cancellation of Contracts With Japanese Steamship Lines

THE preferential traffic contracts between the Chicago, Milwaukee & St. Paul and the Great Northern and Japanese steamship lines, covering export and import traffic to and from the Orient, which the Shipping Board is insisting that the railroads abrogate in order to give Shipping Board vessels a chance for a share in the traffic, were the subject of an informal conference at the Shipping Board offices on February 2 attended by Chairman Lasker and Commissioners Thompson and Lissner of the Shipping Board, Chairman McChord and Commissioners Campbell and Potter of the Interstate Commerce Commission, Ralph Budd, president of the Great Northern, H. E. Byram, president, and R. M. Calkins, vice-president, of the Chicago, Milwaukee & St. Paul, and representatives of the Seattle Chamber of Commerce.

The Shipping Board reaffirmed its position that all preferential contracts between railroads and foreign steamship companies must be abrogated and stated that it could not enter into a contract with the rail lines to take the place of the foreign contracts. The railroad officers expressed their desire to aid the American merchant marine but reaffirmed their previous position that the abrogation of the contracts would only deprive them of revenue with no assurance that the business would go to the American boats, because of the control of a large part of the traffic by the Japanese soliciting agencies and the probability that the contracts would be transferred to Canadian lines.

It is understood that Mr. Budd proposed as a compromise that the contracts be abrogated and that the road agree to turn over to the Shipping Board vessels one-half of the unrouted traffic, giving the other half to Japanese lines in return for the business which they can give to the road. Commissioner Potter is said to have taken the position that the railroad officers would not be warranted in voluntarily giving up the contracts and thereby sacrificing their revenues. Members of the board claim that they have legal authority to compel the cancellation of the contracts but have preferred to try to persuade the roads to cancel them. The railroad representatives were to meet again with members of the board on March 1 with a view to giving their final answer at that time.

The executive committee of the Tacoma Chamber of Commerce has sent a telegram to the Shipping Board in which it "views with alarm" the reported insistence of the board on the abrogation of the traffic contracts between the Chicago, Milwaukee and St. Paul and the Great Northern railroads and Japanese steamship lines.

The New Uniform Export Bill of Lading

Affects Property Transported by Rail and Ship from United States to Points in Non-Adjacent Foreign Countries

By Waldon Fawcett

POSTPONED for one month at the request of the carriers, there will become effective on March 15 a new export bill of lading prescribed by the Interstate Commerce Commission. This is the culmination of a movement initiated more than a year ago. Representations on the subject have been made to the Interstate Commerce Commission by various shipping interests and whereas the rules and regulations prescribing the form of the new through export bill of lading do not fully meet the approval of all interested parties there is reason to believe that the plan worked out at Washington is a fairly satisfactory solution in behalf of the standardization which is admittedly desirable.

The new through export bill of lading is designed for issuance by carriers subject to the Interstate Commerce Act for application to the transportation of property, in connection with ocean carriers whose vessels are registered under the laws of the United States, from points in the United States designated under the provisions of Section 25 of the Interstate Commerce Act to points in non-adjacent foreign countries. In due course, an order will be promulgated by the Interstate Commerce Commission designating points on the lines of carriers enumerated at which information relative to the handling of export shipments by common carriers by water in foreign commerce shall be maintained and at which will be issued through bills of lading in connection with ocean carriers whose vessels are registered under the United States laws.

In ordinary practice it is customary for carriers to furnish bills of lading in connection with transportation over their lines, although large shippers, as a matter of convenience, frequently provide their own. In Paragraph 11 of Section 20 of the Interstate Commerce Act it is specifically provided that any carrier receiving property for transportation "shall issue a receipt or bill of lading therefor." Confirming this obligation the Supreme Court of the United States said in the case of Atchison, Topeka and Santa Fe Railway Company versus United States: "Whatever transportation service or facility the law requires the carrier to supply they have the right to furnish." In this same connection the Commission has assumed that a carrier could refuse to use a bill of lading tendered by a shipper which was of an unusual size or style or did not correspond with the terms of the lawfully published and filed bill.

Reasons for Uniform Bill of Lading

The investigation by the Interstate Commerce Commission which led up to the promulgation of the new export bill of lading was inspired to a considerable extent by widespread expressions of dissatisfaction with the conditions heretofore existing. In the course of a recent hearing before the Merchant Marine Committee of the United States House of Representatives on the subject of theft, pilferage, non-delivery, breakage, etc., in import and export shipments there was, on the part of a number of witnesses, severe criticism of conditions governing bills of lading. At that hearing ocean carriers and especially the United States Shipping Board were accused of putting in their bills of lading provisions exempting them from nearly every sort of liability.

C. E. Dobson, managing director of the Southern Lumber Exporters' Association, declared that almost every ship operator has his own bill of lading and that no two of them are alike. Furthermore, he declared that they were changed from time to time. His comment was that, if the Shipping Board would prescribe a standard bill of lading for all its operators and use a special form for each of the principal commodities, eliminating the "excess verbiage" and "untenable provisions," it would be a great source of relief to shippers. Frank C. Overton, president of the National Association of Waste Material Dealers, ventured to hope that some day the nation would have a standard bill of lading, worded in accordance with the law and free from individual and arbitrary clauses. He particularly attacked the practice whereby a steamship company stamps on its bill of lading a clause in effect as follows: "Steamer not responsible for marks nor for numbers of bales and broken bales or short weight on account of spilling or breaking of bands during the transfer."

Multiplicity of Reservations Objectionable

Various commercial organizations have charged before the Congressional committee that, under stress of war-time transportation conditions, various shipping companies have inserted in their bills of lading reservations that are in open conflict with the Harter Act, approved February 13, 1893. This is the statute which declares to be null, void and of no effect any words or clauses inserted in bills of lading designed to relieve the shipping interest from liability for loss or damage arising from negligence, fault or failure in proper loading, stowage, care, delivery, etc. Spokesmen for the organization of shippers and receivers of goods urged that Congress, in the interest of avoidance of misunderstandings, exert influence to induce the steamship companies to adopt a standard form of bill of lading. Or, if, because of varying port conditions in certain countries it be not practicable to concentrate on one standard form, then, as an alternative, there should be several standard forms adopted designed to meet local conditions.

In the recent representations at the Capitol with respect to the rights that should be guaranteed to the patrons of ocean tonnage, it has been emphasized that whereas every shipper and consignee is not posted as to his legal rights under a bill of lading, nevertheless an ocean bill of lading is supposed by the average merchant to be a negotiable document. He accepts drafts and draws drafts with an ocean bill of lading as security, and, if the supposed obligations of such a bill of lading are not fulfilled, there is proportionate embarrassment to the shipper or receiver of goods who has placed implicit faith in the document. One argument put forth at Washington was that there is as much reason for a standard bill of lading applicable to foreign commerce as for a standard form of insurance policy such as is now in use in the United States.

At one of the sessions of the Congressional Committee on Merchant Marine there was sharp debate on the question whether steamship companies had, in recent years, with unwarrantable frequency and without proper notice changed their bills of lading. Friends of the shipping companies on the committee contended that diligent inquiry showed that no steamship companies have changed their forms of bills of lading in the last three years. The antagonists were not prepared to say that the printed forms had been altered but made the point that in recent years there has been an increase in the number of rubber stamp imprints placed on bills of

lading, such rubber stamp surcharges constituting, in their judgment, changes in the contracts.

Difficult to Interpret

Critical fire was also centered, in the course of the recent discussions at Washington, on the alleged complexity of bills of lading. It was charged that the complexity of the bills in use is increasing rather than diminishing and that there are incorporated a large number of clauses printed in very small type and difficult to interpret. In the course of remarks at the Capitol, Mr. Charles E. Herrick, representing the Institute of American Meat Packers, took the ground that a complicated bill of lading that attempts to defy the Harter Act really injures the shipping interests in that it discourages newcomers in the export field. He recounted that there are many beginners in export trade, located at inland points, who are not versed in the Harter Act and no more are their attorneys. Such persons are apt to accept as gospel all the exemptions that a shipping interest may write into a bill of lading. The shipper, thus confronted, is apt to swallow his loss, but he is also likely to abandon all further effort to cultivate export trade.

In the discussions in Congressional committee much has been made by spokesmen for inland shippers of the difficulties of procuring ocean bills of lading at interior points. Shippers in the interior have testified that they have repeatedly asked for copies of the ocean bills of lading that were to govern particular contracts and have been as often told that these cannot be furnished because the local transportation officials profess ignorance of what form of bill of lading is to be used when the goods reach the seaboard. The shipper feels therefore that he is compelled to accept a contract the terms of which he does not know and cannot know. The interior shippers demanded that there be some provision of law that the freight contract on a shipment from the interior shall govern the terms of the bill of lading rather than be governed by a bill of lading issued subsequent to the receipt of the goods on board the ocean carrier and when it is, of course, too late for the shipper to withdraw them.

Shipping Executives Believe New Bill Will Eliminate Friction

Representatives of the ocean carriers, notably Mr. F. A. Ryan of the International Mercantile Marine Company and J. E. Waldorf of Chicago, have taken issue in Congressional conference with the interior shippers who complained of inability to obtain copies of ocean bills of lading. It was insisted that a shipper located, say in Chicago, should have every facility to ascertain details as to bills of lading inasmuch as the Chicago agents of the shipping companies have on file not only copies of the ocean bills of lading but copies of the connecting line bills. Mr. Ryan stated that, if an interior shipper made a shipment on a through bill of lading, his through bill would provide that it was subject to all the terms and conditions of the local bill of lading in use at the time that the shipment was made. This, he thought, would automatically mean that the date of the through bill of lading would govern the conditions of the local bill of lading which are in force on the day on which the through bill of lading is signed. The shipping executives have further stated in recent conversations with leaders of Congress that they have hopes that all friction and resentment on the part of shippers will be eliminated by the new through bill of lading which is presented by the Interstate Commerce Commission and the form of which was carefully gone over by committees of various trade associations as well as by committees representing the steamship lines before it was submitted to the Commerce Commission.

The present move on the part of the Interstate Commerce Commission constitutes a second effort on the part of that institution to secure the acceptance of uniform bills of lading. On April 14, 1919, the Commission prescribed a uniform export bill of lading and likewise a uniform domestic bill of lading. Upon petition of interested parties this issue was enjoined by the district court of the United States for the southern district of New York, three judges sitting as the statute provided. The majority opinion of the court held that the Commission had no authority to prescribe bills of lading for either domestic or export traffic. An appeal was taken to the Supreme Court which held that the passage of the transportation act of 1920 made the case a moot one and reversed the order of the district court. The district court was directed to dismiss the petition but without prejudice to the rights of the complainants to assail in the future any order that the Commission might make prescribing bills of lading after the enactment of the new legislation.

Transportation Act Makes Standardization Possible

The amendment of the Interstate Commerce Act by the Transportation Act of 1920 conferred upon the Commission authority to make rules and regulations prescribing the form of a through bill of lading. Without loss of time the Commission took steps to bring about the contemplated standardization. Railway carriers and shipping interests were directed to confer with the object of drafting a uniform bill of lading and the Commission made arrangements to distribute 500 copies of the tentative bill to export shippers and other interested parties in order that suggestions and objections might be obtained and there be worked out a bill reasonably satisfactory to all the interests involved.

Not without considerable opposition did the Interstate Commerce Commission proceed with its project. A number of the rail carriers, particularly those in the eastern part of the United States, challenged the power of the Commission to do more than prescribe the "form" as distinguished from the substance of the bill of lading. And counsel for American ocean carriers operating in foreign commerce on the Atlantic Ocean made clear their belief that the Interstate body had no power to prescribe any condition applicable to them without their consent. A representative of the Shipping Board who was present at the hearings on the subject conducted by the Commission likewise voiced the belief that the Commission has no jurisdiction over water carriers. The Interstate Commerce Commission has insisted, through it all, that inasmuch as the act to regulate commerce specifically requires carriers to issue bills of lading it has unquestionably power to prescribe as to the issuance, form and substance of bills of lading. Incidentally the Commission called attention to the fact that the rules and regulations constituting the forms of bills of lading affect the value of the service rendered to the shipper or consignee.

Convinced that it was the intent of Congress to require a uniform through export bill of lading and to have the terms prescribed by the Interstate Commerce Commission the latter proceeded with its task and to that end considered forms laid before it by numerous interests such as the prominent carriers, the National Industrial Traffic League, etc. The forms placed in nomination showed wide diversity and sharp variations in the wording of the embodied provisions. In the drafts put forward by shippers there was sought the benefit of full common-carrier liability from the time a shipment is delivered to the initial rail carrier for transportation until it is delivered to the consignee or his order at destination. Carriers, on the other hand, have naturally sought to restrict their liability to what they account reasonable limits.

Provisions of New Bill of Lading

With this ample fund of suggestions as a working basis the Interstate Commerce Commission evolved the new uni-

form bill which provides in effect that the shipment involved is subject to the terms and conditions of the local form bill of lading not inconsistent therewith. Certain physical features of the new bill will presumably meet with general approval inasmuch as there was substantial unanimity of demand for them on the part of both shippers and carriers. For example, there is provision of a bill of lading of a width convenient for use in an ordinary typewriter. Also to be cited is the stipulation of a form which permits all the printed matter to appear on the face of the sheet. This is a minor detail that is important because the number of copies which must be made in a set of export bills of lading is so large that it is desirable to use thin paper. No requirements have been made as to the size of type or color of paper.

Such has been the demand for specimens of the uniform through export bill of lading that the supply of the Interstate Commerce Commission has been exhausted. Copies can be obtained, however, upon payment of 5 cents each by addressing the Superintendent of Documents, Washington, D. C., specifying I. C. C. 7230 (No. 4844). The Contract Terms and Conditions attached to the new standard form make a rather voluminous document, subdivided into three sections. Part I covers the service of transportation until delivery at the port of embarkation. Part II deals with the service after delivery at the port first mentioned and until delivery at the port mentioned second—the port of debarkation. Part III is with respect to service after delivery at the port second mentioned and until delivery at ultimate destination, if destined beyond that port. The form has been prepared with due recognition on the part of the Interstate Commerce Commission of the limitations upon its jurisdiction over the ocean carriers.

This limitation is reflected in the disposition of some of the requests made by shippers. For example, the shippers urged that provision be made specially at a number of places in the bill of lading for notice to the shipper or consignee, or both, of changes which would otherwise be unknown to them, such as change in vessel. Most of the railroad interests are represented as not objecting to giving such notice, but, on this count, the Commission came up against a stone wall in the form of objection by the ocean carriers, exception being taken to the plan on the score of the clerical labor that would be involved in the case of shipments transported in a vessel other than that for which they were originally intended. The new through export bill of lading stops short, in certain other respects, of the desires of shippers at inland points because the Interstate Commerce Commission holds that the Cummins amendment, so called, does not apply to transportation from a point in the United States to a point in a non-adjacent foreign country.

In connection with the order of the Commerce Commission anent the new bill of lading, the Commission has disapproved a number of requests that have been received for permission to use old bills of lading or forms with no conditions printed thereon. The Commission feels that the use of makeshift bills would occasion much confusion in banking circles and among persons not dealing constantly with bills of lading. Moreover with uniform bills of lading in use throughout the country there will be little need for resort to irregular bills.

Pacific Coast Pool Discussed With President and Shipping Board

THE committee representing the various ports on the Pacific Coast, which has been working on a tentative plan for the acquisition of the combination passenger ships owned by the Government and operated in the Pacific, came to Washington on February 8, called on President Harding, and subsequently met with Chairman Lasker and the Shipping Board.

President Harding told the comittee that nothing concerned him more in domestic legislation than providing proper aids to establish an American merchant marine, and that it was one of his earnest hopes to see such aids provided. The President bespoke his deep interest in the formation of a company, the stock of which should be popularly owned by the people of all the Pacific Coast, for the development of the American merchant marine in the Pacific, with the hope of using the united assets of all to develop each port in the interest of the whole.

Chairman Lasker reviewed the needs of the United States on the Pacific Ocean, and pointed out that if ruinous competition prevailed between ports and companies there would not be that opportunity for the development of the American flag in shipping in the East that there would be through a popularly owned company, uniting all the ports of the Pacific Coast, thus cutting down overheads, which might make it possible for some ports to operate ships of certain types, the trade for which otherwise could not be developed.

The Shipping Board made no basis of proposal as to the price at which it held its combination passenger-and-cargo ships, but did stress that, in line with the Jones Act, it was its duty to make sure that the ships passed into private hands at the earliest moment compatible with the Government receiving a proper price. Until the President has delivered his address on government aid to private shipping to Congress, and Congress has taken action on same, the Board did not feel in a position to name a price. Immediately after Congress has expressed its will on merchant marine legislation, the Shipping Board desires to dispose of its Far Eastern passenger ships, feeling that through private operation the trade with the Orient can be much better developed than through Government operation. On behalf of the Board, Mr. Lasker asked the committee to bring about agreements in principle that would iron out the difference between competing ports and make the formation of such a company possible at that time.

Mr. Lasker made it plain that there was nothing in the suggested company that precluded any and all ports and all individuals purchasing any cargo ships desired, on the identical price and terms that any company, including the proposed one, could obtain. Mr. Lasker also pointed out that if a higher bid for the passenger ships other than the bid of the contemplated company was received, the higher bidder would, of course, obtain the ships; but he expressed the fear that unless such a company as contemplated was brought about, there might be no group strong enough to acquire the vessels, and therefore it became the duty of the Shipping Board to attempt to create a customer if none existed. In the creation of such a customer however the Shipping Board could only contemplate one that represented all the people of the Pacific Coast organized in the national interest.

The representatives of the coast ports were unanimous and enthusiastic in subscribing to the Shipping Board's belief that a company such as is proposed was essential for the country, for the Pacific Coast, and to carry out the purposes of the Jones Act. The only reservations were that each port should be free to reach its maximum development, and that the parent company should be so formed as to protect the interest of each port. The committee felt sure that this could be achieved. The committee stressed that while any new company that was formed desired to pay all that the ships were worth, any purchase would have to be based on the ships being acquired at a price that made proper earnings possible, if capital was to be attracted.

Developments in Marine Insurance

Standard Open Policy Drafted—Marine Business Picking Up—Oil Storage Hazards—Cleaning Tanks by Rule—Shipowners' Liability in the Courts—Proposed Lloyds' Legislation

By "Bordereaux"

AN important forward step has been taken by the American Institute of Marine Underwriters in endorsing the report of a special committee, recently submitted, on the much-discussed subject of a standard open cargo policy form. This is the reform that the banks have been clamoring for, that the decision of the English High Court of Justice necessitated, if the time-honored insurance certificate were not to lose caste altogether, and which a large number of progressive underwriting offices have been agitating for. To secure it there has been a great deal of hard work done for nearly a year by the special committee of the Institute, and now that it is finally achieved there is a rather disconcerting suspicion that the powerful brokers may bar its general adoption—such, unfortunately, is the influence of "big brokerage" in these United States. The banks will, undoubtedly, welcome it; their association has it under consideration.

This piece of real constructive work sweeps away practically all of the misunderstandings and obscurities connected with the archaic phraseology of the venerable marine policy, so that it will no longer require an expert in occultism to determine just what is covered and how; it clarifies and simplifies the contract and all of its involved clauses, and supplies a standard, uniform, brief but comprehensive document of all the salient terms and conditions. It is, we repeat, a distinct forward step; something that has been needed and that ought to be in general use. But, alas, custom is strong with the older offices, as self-interest is with the brokers, and it may be pigeon-holed after all.

Singapore Losses

A CONTINUOUS run of serious losses on craft in the harbor of Singapore has led underwriters to inaugurate cooperative action through a special committee for purposes of investigation. Unseaworthiness and over-loading are generally given as the chief causes of these reverses. It is now suggested that a surveyor be appointed to supervise craft at Singapore, the expenses to be met by the interests concerned. American underwriters are less involved than British.

Marine Writings Are Picking Up

WHILE it is admittedly under pre-war volume there are decided indications that the marine insurance business is on the gain. This is accounted for by the encouraging increase in export trade, which last year was but slightly under the normal; the heavy overstocks of American manufactured goods accumulated by foreign buyers during the frenzied purchases of 1919 and 1920 are being worked off, and normal requirements are being filled in a sane and healthy manner. Refined sugar is moving in large quantity to Europe, and food and other supplies for Russian relief are going forward steadily through both Baltic and Black Sea ports. Gold bullion, in considerable amount, is moving from Swedish ports to the United States—probably Russian gold sent by the Soviet government, or by private interests of that country, for the purchase of supplies to supplement the shipments of the United States. A glance at the manifests will show that imports from Europe are steadily improving in volume. The outstanding unfortunate feature of the times, from the viewpoint of the underwriter, is the very low rates quoted by both British and Continental offices. Their motto appears to be, "Get the Business."

Peril in Oil Stowage

UNDERWRITERS have been greatly interested in the recent decision of a British court awarding heavy damages to an American company, owner of the cargo of oil lost when the *Clan Gordon* capsized off Hatteras in 1919. There was a deep cloud of mystery surrounding this disaster, for the vessel left New York in apparently seaworthy condition and turned over in calm weather. By the finding of the Court the steamship company was at fault in failing to instruct the captain to provide water ballast, thus permitting the vessel to sail in unseaworthy condition.

The important point to this case is that care has to be exercised in the proper stowing of a cargo. The average layman is of opinion that the only requisite in loading a ship is to get all the cargo possible on her. The truth is that both the loading and discharge must be scientifically managed, for not alone is it possible by poor loading to impair the stability of the vessel, but by improper discharge the ship may be so strained as to do serious injury to the hull.

Rules for Cleaning Oil Tanks

VALUABLE constructive work has been done by the Marine Fire Hazards Committee of the National Fire Protection Association, and its findings, resultant from more than a year of conscientious work, have been embodied in a report just submitted by a sub-committee. These findings suggest practical ways of combating the fire hazard to vessels, and are based upon the best judgment of recognized experts from the United States Bureau of Mines, the United States Army and Navy, the Shipping Board, and of leading oil companies and dry dock establishments.

The sub-committee's report, while not applying to urgent emergency repairs, gives careful consideration to proposed regulations for the freeing of oil tanks, bunkers and compartments of flammable and explosive vapors previous to entering for any purpose or making repairs. It is proposed to impose a prohibition against making repairs of any kind to any tank, compartment, bunker or other container or space previously containing explosive and flammable liquids, until the requirements hereinafter outlined have been complied with.

The process of freeing such containers of vapor shall be as follows:

1. (a) Tanks shall be closed and live steam blown into the tanks or space to be cleaned and all pipes leading thereto or therefrom for a period of time to be governed by the conditions and the nature of the oil carried. Vent pipes shall be proved and left open. Inasmuch as the time for

steaming will be determined by the foregoing no definite rule is laid down to cover all contingencies, but a carefully worked-out table accompanies the report, and is recommended for use as covering average general conditions. By this table the time of steaming is arrived at by taking the number of hours given in the table, under the actual size of steam connection corresponding to the value given for the volume in cubic feet of the compartment to be steamed. These calculations are based on a steam pressure of 100 pounds per square inch. In steaming tanks the last one-fifth of the steaming period should be carried out with manhole plates or tank lids open to the atmosphere.

Upon completion of this operation the tank or space must be ventilataed thoroughly by means of wind sails, forced or induced draft. Thereafter, specimens of air shall be taken from the tank by a competent chemist, vouched for by the American Bureau of Shipping, and shall be analyzed or tested by him; and should the presence of explosive or inflammable gases still be detected the steaming and ventilating process shall be resumed and continued, after subsequent tests, until the air is pronounced pure.

There are also rules for cleaning tanks for shipyard repairs; also with respect of ventilation, use of tools and lights and gas masks, and the precise kind of permit the foreman must have over the signature of the superintendent.

The National Fire Protection Association is to pass upon these suggestions at its annual meeting next summer. It is more than probable that they will be adopted substantially as they stand.

Loss on the Northern Pacific

LONDON underwriters sustained a loss of $1,200,000 when the Admiral liner *Northern Pacific* was burned and sunk off Cape May on February 9. It is generally reported in the New York market that the rate was ⅜ percent for the trip to Chester, Pa., and for builders' risk while repairs were effected at the yards there. The insurance was captured by London at a rate under what our underwriters were willing to accept, and the heavy penalty falls entirely on the British insurer, less such reinsurance as may have been secured.

The fact that this vessel was one of the fleetest and finest under the American flag, equipped with the most approved safeguards to safety, renders the cause of her destruction peculiarly interesting to underwriters everywhere. If it turns out to have been the dreaded "flare back"—a peril too closely associated with previous losses of oil-burners—there will probably be promptly inaugurated investigations looking to the introduction of safeguards for the reduction of this hazard.

Oil Tank Overflows

AT the risk of appearing to give undue space to oil perils we venture to call attention to the singular problems arising out of the overflowing of the fuel oil tank of the *Cardiganshire* when she was taking on her oil supply at Colon recently. She was bound from Seattle to the United Kingdom. The tank was allowed to overflow in the operation, and considerable damage was done to cargo in the 'tween decks. Who is going to be held responsible? The courts will doubtless be called upon to decide, but, in the meanwhile, there is much speculation on the subject.

Filling fuel tanks is certainly connected with the management of a vessel, and yet the courts will undoubtedly again construe the Harter Act in a way to relieve the carrier of liability, although the consequences of the negligence of one man's servant will thus have to be borne by an innocent party. The underwriter can scarcely be held responsible, for a careful survey of the usual form of the "perils clause" will fail to disclose any mentioned hazard which seems broad enough to include oil damage; certainly not negligence in the filling of oil tanks. It would therefore appear that the unfortunate cargo owner is to be without redress; and that is a hard thing, because he, of all others, was innocent of the cause of the damage, and yet he may be obliged to sit by and see those who were responsible pass scathless through the meshes of the law.

Proposed Lloyds' Legislation

IN view of the long-continued and often acrimonious discussions anent the placing of insurance on American risks with Lloyds, London, and other unauthorized insurers, it is important to note that, as a result of numerous recent conferences between the conflicting interests and the New York insurance superintendent, a tentative form of a marine insurance bill has been drafted that is acceptable to both brokers and representatives of admitted foreign companies. When finally corrected and agreed to by the marine conferees the bill is to be given full publicity and all interests in any way concerned are to be invited to have a part in criticizing and improving it. The Insurance Department takes no position in the matter, either for or against, and only desires to have all interests advised of what is under way and to have a part in the proposed legislation.

Shipowners' Liability in the Courts

UNDERWRITERS have been much interested in the decision recently handed down by United States Judge Jeremiah Neterer, of the Western District of Washington; and for better reasons than that it represented a reversal by his Honor of himself, as of court record of but two months previous. It had under consideration the celebrated case of the steamer *Princess Sophia,* wrecked October 25, 1918, and it grew out of the defense of the ship's owner, the Canadian Pacific Railway Company, against damage suits brought by two hundred claimants because of the loss of three hundred and forty-three lives and much valuable baggage and cargo. The defendant was allowed by the court to plead limitation of liability for loss of life, baggage and cargo. The vessel herself being practically worthless, the claimants will find themselves limited to approximately $8,000 aggregate damages. The captain of the vessel had refused aid when offered by other steamers standing by; but this action, the railway company insisted, it had no hand in. On the question as to whether insurance might be regarded as an interest in the vessel Judge Neterer decided that it could not, citing in support of his position the decision of the Supreme Court in the case of the *City of Norwich,* to wit: "We are not only satisfied that the law does not compel the shipowner to surrender his insurance in order to have the benefit of limited liability, but that a contrary result would defeat the principal object of the law."

Launch of Steamship Matiana.—The steamship *Matiana,* built for the British India Steam Navigation Company by Messrs. Barclay, Curle & Company, Ltd., was launched on January 26 from the firm's West Yard, Scotstoun. The vessel is of the intermediate cargo and passenger type, 485 feet by 58 feet 3 inches by 36 feet, with a gross tonnage of 8,970, and will be propelled by twin screws driven by Parsons double reduction geared turbines, capable of developing a sea speed of 14 knots. The boilers and bunkers are so arranged that the vessel can work either on coal or on oil fuel. Accommodation is provided for 105 first class and 41 second class passengers, the Inchcape system of inner room being adopted so as to give the maximum lighting to living spaces.

Shipping and Shipbuilding In Great Britain

Capital Plentiful for Shipping—High Costs and the Shipping Depression—Shipbuilding Prospects Gloomy But Not Entirely Hopeless

By W. H. Wendon

THE most remarkable feature of the British shipping industry at the present time is the rapidity with which new issues of capital are being subscribed by the public. Three very well-known companies—the Union-Castle Line, the Clan Line and the African Steamship Company—invited the substantial amounts of £2,000,000, £1,500,000 and £1,500,000 respectively. Despite the depressed condition of the freight market and the poor position of trade generally, the new capital was acquired with consummate ease. It is no exaggeration to say that, had the total sum invited by these three companies been ten times what it was, it would still have been forthcoming. As I have hinted, the reasons for this rush to invest in shipping securities are rather obscure, and the fear is already being expressed in responsible shipping circles that, emboldened by this glut of money for liner company issues, tramp concerns of the mushroom type will take advantage of the situation and float wild-cat companies similar to many which were born during the war and post-war boom. Many companies have steamers standing in their books at far above their present values, and investors are being urged to view the solicitations of the managers of these concerns with something amounting to suspicion.

Seamen Accept Cut in Wages

The most significantly optimistic note which the shipping trade enjoys at the moment is in regard to wages. Sailors, firemen and stewards in foreign-going vessels have agreed to a reduction of £2 a month, the cut in the wages of coasting employees being ten shillings a week. This is in contrast with the shipowners' original proposal of a reduction of £3 a month and fourteen shillings a week respectively. Both parties appear to be well satisfied with the settlement. Higher ranks will receive proportionate reductions. A feature of the new scale is that thirty shillings of the £2 will be knocked off on March 1, and the remaining ten shillings two months later. In the words of the official statement: "The settlements are conditional on there being no general and very appreciable improvement in the chartering rates of steamers between January 1, 1922, and the dates on which the reductions fall due."

The position of British shipowners *vis à vis* their Continental competitors is arousing a good deal of interest, and no small comment. The matter has been brought to a head by the President of the Chamber of Shipping of the United Kingdom (Sir Owen Philipps) and deputy chairman (Sir Frederick Lewis) receiving an influential deputation of iron and steel manufacturers on the subject of freight rates on metals. Iron and steel industrialists declare that all costs of production have been reduced very considerably, and at the conference referred to, it was maintained on their behalf that a point had been reached where it was found that the question of freight was the deciding factor whether business should be placed in this country or on the Continent.

Freight Rates on Metals

Sir Owen Philipps, in his reply, pointed to the heavy fall in freights, which he described as being in some cases little more than barely living rates. Fifteen to twenty percent of the whole tonnage of the British Empire is now laid up, and over 1,000 modern steel steamers owned by the United States Shipping Board are out of commission on account of freights being so abnormally low, and, moreover, many British vessels at present engaged in trading are not doing so at a profit. Bearing these salient facts in mind, Sir Owen Philipps said it was desirable to consider whether the f.o.b. prices at which British manufacturers offer their commodities for sale compare reasonably with f.o.b. prices of their foreign competitors. He instanced the fact that, in the case of one recently placed great steel contract, the difference in prices tendered was so enormous that, even if the British shipowner had been satisfied to carry the material for nothing, the British manufacturers' prices would not have been accepted. There was no question of advantage or otherwise in regard to freight charges, as, in the South African trade, the rates of British ships from the United Kingdom and the Continent were identical. Moreover, the British lines, in order to assist the British manufacturers, offered to carry the cargo at whatever rates were taken by foreign lines.

In concluding his spirited reply, Sir Owen Philipps maintained that there was no denying the fact that Continental countries had in some cases got ahead of us. There were many factors which had contributed to this result, such as longer working hours and cheaper labor, the exchange and generally lower cost of production. He believed that British trade, commerce and shipping were faced with very difficult times for the next few years, and the closer they worked together the better.

Economical Ship Operation Vital

High costs and the shipping depression generally were the subject of some interesting remarks by Mr. A. D. Mearns, director and general manager of the Cunard Line at Liverpool. Analyzing the situation, he pointed out that at a recent date there were over fifty million tons of shipping looking for employment—a figure so vast that it was difficult to comprehend. A large amount of this tonnage is tied up in the ports of the world, but, notwithstanding this, Lloyd's Register's latest returns show that at the beginning of the current year there were over 1,000 vessels under construction, with a gross tonnage of nearly 4,500,000. This tonnage, said Mr. Mearns, must be absorbed before they could look for profitable trade, but it was clear that for a long time there would be a floating element of tonnage which would have a detrimental effect upon the profitable operation of the remainder.

The question resolves itself into one of costs, and the ship which can be operated most economically and provide an efficient service is the one that will get the business. The proposition is a simple but vitally important one. With the price of construction three or four times above the pre-war figure, it is obvious that new tonnage is under an immediate disability with its competitors. The sequel is to be found in the idle shipyards of the country, where contracts have been cancelled and thousands of tons of shipping is suspended.

Sir Walter Runciman, who created a certain amount of sensation by repurchasing eight of the steamers which he sold at the top of the boom to the unfortunate Western Counties Shipping Company—taking them back, of course, at a fraction of the sum which he received for them—has just had delivered to him the initial steamer of six which are to run

in conjunction with the re-purchased eight. Messrs. William Doxford & Sons, of Sunderland, are to build these six boats, and the last is to be delivered by June. As to the depression, Sir Walter Runciman is too wise to attempt to predict the length of it, but in his judgment we have a long way to go before we reach rock bottom. He does not think it will be this year, or even next year. He ascribes the reason for his and his colleagues' re-entry into shipowning as being due to the fact that they prefer to manage their own money than leave it in the hands of the Government "to waste."

Shipbuilding on the Clyde Slack

Clyde shipbuilders, in common with those in other great construction centers, continue to look to the future with anxiety. In this connection it is noteworthy that in some quarters—notably in the lay press—false deductions are being drawn from the fact that in January the Clyde placed into the water the record total of 56,414 tons gross, representing nine vessels. Prior to this the highest tonnage launched on the river was 39,910 tons in January, 1920. The reason for the figure climbing to 56,414 tons is, of course, that it included such large vessels as the P. and O. liner *Bendigo*, of 13,100 tons, and the *Athenia*, of 12,000 tons.

Far from there being a "boom," as is suggested by the uninitiated, the launching of these and other vessels simply means that so many additional berths are rendered vacant. The most important new contract—indeed, almost the only one worth recording this month—is the twin-screw steamer to be built by Scott's Shipbuilding and Engineering Company, of Greenock, for Messrs. Alfred Holt and Company's Blue Funnel Line. Her dimensions will be 400 feet, by 52 feet, by 32 feet, and her most interesting feature is that she will be propelled by Scott-Still engines, which represent the latest development in marine propulsion, and embody a new principle consisting of a combination of an oil engine and steam engine. The boat's twin-screw machinery will develop 2,500 brake horsepower and particular significance is attached to this decision to install an entirely new class of machinery.

Holt Liner To Have Still Engines

Details of the "Still" system are not devoid of interest. It appears that rather more than a year ago Scotts' Shipbuilding and Engineering Company acquired a license for the manufacture of the Still engine, and built an experimental set, upon which prolonged trials were carried out. The results are said to have definitely proved that the "Still" engine has a lower consumption than any other type of prime mover now being manufactured commercially. In the new vessel for the Holt Line, two of these motors, each of 1,250 horsepower, will be fitted. It is claimed that a thermal efficiency is reached some 15 or 20 percent in excess of that of the ordinary four-cycle Diesel engine. Although this will be the first ship equipped with "Still" engines, a great amount of experimental work has been carried out in the past ten years.

New Liner for Glasgow-Canadian Service

The passenger and cargo steamer *Athenia*, to whose launching I have already referred, is to engage in the Anchor-Donaldson Line's Glasgow Canadian service. She has been constructed by the Fairfield Shipbuilding and Engineering Company, of Glasgow, is of the shelter deck type, with straight stem and cruiser stern, and has two steel masts. Her principal dimensions are 520 feet, by 66 feet, by 42 feet, her gross tonnage is 12,000, and her loaded draft 27 feet 8 inches. The propelling machinery consists of two sets of Brown-Curtis double reduction geared turbines. Steam is supplied by three double-ended and two single-ended boilers, arranged to burn oil, and with a working pressure of 210 pounds per square inch. Accommodation is provided on the bridge deck amidships for 354 cabin passengers in staterooms arranged for one, two and four berths. On the shelter deck, which extends almost the full length of the ship, accommodation is provided amidship for 162 cabin passengers. The third-class passenger accommodation is situated on the upper deck and main deck, the cabins being fitted for two and four passengers in each room.

Shipping and Shipbuilding Prospects Not Hopeless

On the occasion of the launching of the *Athenia*, Sir Alexander Kennedy, managing director of the Fairfield Shipbuilding Company, referred at some length to the shipping and shipbuilding depression. He maintained that, while the immediate prospects are not bright, the position is not entirely hopeless. In pointing to the seriousness of the depression, he recalled that in 1908—the worst pre-war year within recent times—the total tonnage commenced was 787,500; in 1909 it was 1,165,000 tons; in 1910 1,349,000 tons; in 1911 1,904,000 tons; in 1912 2,099,000 tons; and in 1913 1,855,000 tons. Passing to the war period, we find that, in the artificial boom of 1919, there were commenced vessels representing 2,391,000 tons, and in the continuation of that boom throughout 1920 there were 2,351,500 tons. But in 1921 the total was only 518,300 tons. The slump last year came with startling suddenness, and of vessels commenced the total was practically one-third less than that of the previous worst year. Turning to costs and values, Sir Alexander Kennedy declared that there would have to be a full realization of the actual facts, and a determined effort on the part of everyone to bring values and costs into closer relationship.

Labor Troubles

At the time of mailing this review, the labor outlook in the engineering industry in Great Britain is a dubious one. Negotiations are in progress between the masters and the men, but the results are so far unsatisfactory. The position is as follows: During the war and since, it has been the common practice for the unions in the engineering shops to say exactly what overtime should be worked. Not unnaturally, the employers wish to alter this. As the result of a conference between the Engineering and the National Employers' Federation and the representatives of the workers, proposals were put forward which in effect gave each employing firm the right to dictate the circumstances in which overtime should be worked. These proposals, endorsed by the executive of the Amalgamated Engineering Union, went to a ballot of the men. In the result, 35,525 voted in favor of the proposals and 50,240 against, or a majority of 14,715 against accepting the terms. The position at the moment is that the decision has been officially reported by the union to the employers, who are considering what next step can be taken.

Scandinavian Shipping

The statistics recently issued by the Norske Veritas show that the Norwegian merchant fleet at the beginning of this year comprised a total of 2,500,000 tons, or an increase of 200,000 tons as compared with last year.

The Swedish mercantile marine with a total of 1,090,000 tons shows a net decrease of 10,000 tons.

The Danish mercantile marine has increased during the last year by 85,000 tons, making a total at the commencement of the present year of 870,000 tons.

At the end of 1921 there were under construction in Sweden 38 ships of 86,640 tons, in Denmark 38 ships of 82,233 tons, and in Norway 53 ships of 77,330 tons. However in all three countries work has been suspended on a large number of vessels.

The New White Star Liner Homeric

Magnificent Express Steamer for High Class Transatlantic Travel Arrives in New York on Maiden Voyage

THE *Homeric* of the White Star Line should be of particular interest to the marine field because she is the type of steamship that is most needed today. Her success as a business venture is practically assured. Whatever may be the losses suffered in the carriage of freight, due to the world surplus of cargo ships, it will be some time before there are enough passenger ships to take all of the ever-increasing traveling public. Passenger fares are higher than they ever were and the *Homeric*, due to her superior accommodations, will be able to command the maximum rates.

Designed with a definite view of providing the greatest possible degree of personal comfort to each and every passenger, yet ranking as one of the greatest transatlantic liners, the *Homeric* is a ship of distinctive character. The facilities of a private yacht exist in her for rendering intimate, personal service to the individual, the family, or the tourist party. In her bedrooms the old-time upper berth has been eliminated, and with it generations of tradition; in her dining rooms small private tables, in varying sizes, predominate.

(From a painting by Charles Dixon)

White Star Liner Homeric

Principal Characteristics

Length	777 feet 0 inches
Beam	83 feet 0 inches
Depth, bridge deck to keel	100 feet 0 inches
Horsepower, reciprocating engines	28,000
Speed, normal	20 knots
Gross tonnage	33,526
Displacement, tons	42,000
First class passengers	491
Second class passengers	422
Third class passengers	1,740
Crew	750

Upon the completion of the *Majestic*, the world's largest ship, the White Star Line will have three vessels on the weekly service between New York, Cherbourg and Southampton, having a total tonnage of (*Majestic*, 56,000; *Olympic*, 46,439; *Homeric*, 33,526) 135,965 gross tons.

Interior Arrangement

A distinctive feature of the *Homeric* is the size of her public rooms which in some cases are larger than similar rooms on the *Olympic*. The lounge, for example, is considerably larger than the lounge on the *Olympic*. The arrangement of the public rooms, which are on the upper deck, is in the form of an imperial suite, each room being distinguished by an impressive and marked character.

At the forward end of the deck, under the navigating bridge, is a drawing room, with large plate glass observation windows. Next comes a reading and writing room, and next the lounge. Beyond this is a music room, and still further on the smoking room with a glass enclosed sun veranda completing the group. The view down the full length of the rooms, at the sides, from drawing room to sun veranda, presents an unbroken vista of 340 feet.

The Lounge

The architectural design and adornment of the lounge on the *Homeric* reminds one of the interior of a Roman mansion. Its length is 94 feet, its width 47 feet, and its ceiling is 20 feet high, with a great central dome of amber glass through which the light comes as through champagne.

On either side of the room is a colonnade of fluted Doric pillars, with bases and capitals richly gilt—a commanding decorative feature, with tall windows between, from which the light falls through harmonious draperies.

The color tone of this sumptuous room, ivory and gold, is relieved by blue. The ceiling has deeply carved panels in gilt against a ground of old blue. A carpet of wonderfully deep pile has large circular designs of blue and old rose on a ground of gold. The central part of this carpet is removable, uncovering a ballroom floor inlaid in a design of stars, in two kinds of walnut. This space has a capacity for 300 dancers. When the dancing space is not in use the entire lounge is arranged with tasteful groups of beautiful furniture, each of a distinctive style of period, and noteworthy for its rich and varied upholstery.

At either end of the room are large canvases, one portraying Columbus landing on the soil of the New World, the other his reception by Ferdinand and Isabella. Smaller panels, at the corners of the room, represent in classic figures the elements—earth, air, fire and water.

Library and Dining Room

The reading and writing room is just forward of the lounge. Book cabinets are installed along the forward wall. Double writing desks of mahogany with ebony ornaments are placed along the sides in recesses lighted by casement windows. The arm chairs for the desks, which revolve on ball bearings, have their bases fixed.

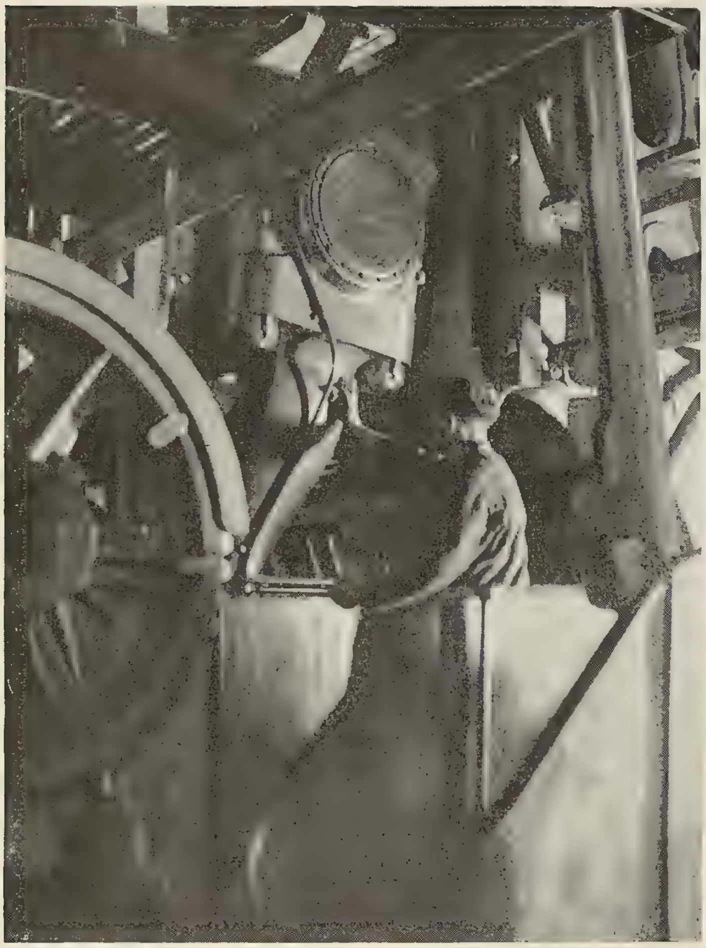
A green marble fireplace, having winged seats, is fitted on one side of this room. In the center of the room is a great round reading table located under a skylight. The color tone of this room is ivory and olive green with a touch of old rose in the carpet and hangings.

Next forward of the library is the drawing room, reached through two square arched openings. This is a charming observation post, giving a wide view ahead, through broad plate glass windows. Everything here is light and airy, like a summer garden. The furniture is chiefly in white enamel—graceful chairs and settees, cushioned in green velour; circular garden sets in lattice, for palms and ferns, and small round tables, with choice marble tops. The hangings are in delicate solid colors.

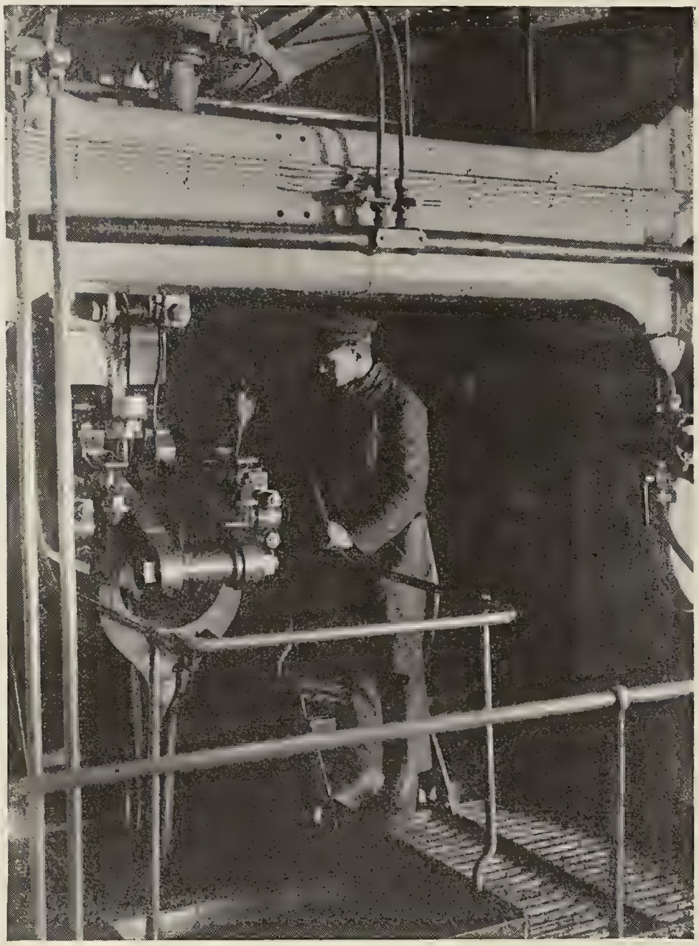
The Music Room

The special feature of the music room is the light touch with which the joyous character of music is expressed in its decorations. The carpet is very delicately colored with great nosegays of pink rosebuds on a ground of soft gray while the border is a pale blue.

On the walls are two large paintings, done in the manner of tapestries, with scenes from Mozart's opera "The Magic Flute"; on one hand is the sleeping princess approached by the Moor; on the other, the elfin bird catcher making magic music to his fantastic little lady love. This room has a mantel in delicate marble with bronze ornaments and mirrored panels surmounted by symbolic ebony carvings on a gold ground.



Crosshead End of Connecting Rod



Showing Link of Valve Gear

The Smoking Room

The smoking room is a lofty rectangular apartment, 38 by 50 feet, its high walls wainscoted to the top in small panels of dull-finished walnut, and with a ceiling of carved wood, done in flat white, the room conveys at first glance a message of dignity and repose.

The greater dimension is across the ship, terminating on either side in bow windows 18 feet high, hung in silk curtains of buff and olive, in perfect harmony with the ripe tone of the walls and the opulence of the massive overstuffed pieces, some in colored wool tapestries, others in deep green morocco, with which the room is furnished. Beside each window is a tall-backed winged chair in red morocco, and on either side of a marble fireplace is a great tapestry armchair, promising the ultimate in comfort. In suitable positions are small, marble-topped tables.

Let into the upper walls are four laıge panels done in oils in the Dutch manner, still life studies of fruits, flowers and game, flanked by carvings symbolic of sports, while over the mantel is a large painting of a young woman mounted for the hunt.

Beyond the smoking room, and reached from it by an arched exit, up three broad steps, is a glass enclosed sun veranda, from which a clear view astern may be obtained.

The First Class Dining Saloon

The dining saloon, which is situated on *D* deck amidships, has a seating capacity for 500 persons. A great inverted dome of crystal pendants, which reflects the brilliancy of hundreds of concealed electric bulbs, centered in a ceiling of white and gold, is fitted over the lofty central portion.

There are galleries on both sides from which an impressive view of the room below may be had. The color tone of the dining room is jade green, ivory and gold. The tables are mahogany, the arm chairs mahogany frame with seats and back cushions of morocco.

Staterooms and Baths

On this ship the staterooms might be more properly called bed rooms. The oldtime upper berth has given place to twin metal beds with box springs and hair mattresses. The smaller rooms have single metal beds either of the conventional or berth bed type. Many of the rooms have a shower bath and toilet attached and a large number have fixed wash basins with running hot and cold water. The suites are fitted with private bath rooms and there are also an unusual number of public bath rooms.

Special Features

The following are among the special features with which this ship is equipped: A complete telephone system supple-

Striking Interior Views on White Star Liner Homeric

ments the usual installation of electric bells for service calls; two electric elevators are situated in the first class quarters and one in the second class; a gymnasium for both men and women; an electric ray bath; hair dressing parlors; a dark room for amateur photographers and a typewriting room.

The *Homeric* was built at the Schichau yard in Danzig, Germany, and was just about ready for service when the war broke out in 1914. She remained in Danzig until 1919, when she was taken to Hamburg, where the interior work necessary for her service in the White Star fleet was finished.

Oil Tanker Fort McHenry Launched

THE tanker *Fort McHenry* was launched at the Baltimore Dry Docks lower plant, Locust Point, Baltimore, Md., of the Bethlehem Shipbuilding Corporation, Ltd., on February 1. Mrs. John Philip Hill, wife of Congressman Hill, of Maryland, sponsored the vessel.

The vessel is classed at American Bureau of Shipping rating A-1-E and at Lloyd's rating 100-A-1, both with the

Tanker Fort McHenry Just After Launching

notation "carrying petroleum in bulk." The construction and equipment are in accordance with the latest rules of the United States Supervising Inspectors of Steam Vessels.

The principal particulars of the *Fort McHenry* are:

Length, overall, 354 feet 6 inches.
Length, between perpendiculars, 340 feet 0 inches.
Beam, molded, 49 feet 0 inches.
Depth, molded, 28 feet 7 inches.
Load draft, 23 feet 6½ inches.
Deadweight tonnage, 6,050.
Speed, 10 knots.
Type of engine, triple expansion.
Size of engine, 23 inches by 39 inches by 65 inches by 42 inches stroke.
Indicated horsepower, 2,000.
Number of boilers, 2.
Type of boilers, single end, Scotch.
Size of boilers, 15 feet 6 inches by 11 feet 5¾ inches.
Kind of fuel, oil.

The vessel is built on the Isherwood system of longitudinal framing, with a straight stem and semi-elliptical stern. The machinery is aft. The cargo space consists of 14 main cargo oil tanks and 8 summer oil tanks separated by oil-tight transverse and longitudinal bulkheads. A deep tank is fitted between the pump room and fore peak for fuel oil, with the hold and 'tween decks above the tank available for dry cargo.

The *Fort McHenry* will be completed, ready for service, about April 1.

Non-Toppling Block for Boat Falls

IN compliance with a recent ruling of the United States Steamboat Inspection Service that "when more than one lifeboat is served under one set of davits means shall be provided that will prevent the davit tackle from twisting or capsizing and that will permit the tackles being readily rounded up for the purpose of launching the remaining lifeboat under such davits," the Steward Davit and Equipment Corporation, New York, has developed a non-toppling and non-twisting block to be used for lifeboat falls.

The principle evolved to prevent these blocks from capsizing or toppling lies in definitely confining the path of each rope in the upper part of the lower block and also by providing a very wide mortise, easy running sheaves and by

The Conventional Blocks

The Steward Blocks

keeping the center of gravity of the block low down. The sheaves are mounted on large bearing pins and, although they are bronze bushed, provision is also made for lubrication.

By flaring the upper portion of the side plates of the lower block, it has been possible to utilize the rivets and spacing pieces as runners to insure a line entering and leaving the block without binding or toppling. Just sufficient clearance is provided for an easy run out of the block on the opposite side. A heavy well-proportioned swivel link is supplied in the bottom of the lower block for attachment directly to the release gear in the lifeboat.

On the side of the lower block, the non-twisting arrangement is fitted. This consists of a flat bar attached to the block to which is shackled a length of light wire rope connected to a similar pendant attached to the opposite block at the other end of the boat. This arrangement prevents twisting of the blocks and has been recommended by the British Board of Trade as well as having been accepted by the United States Steamboat Inspection Service.

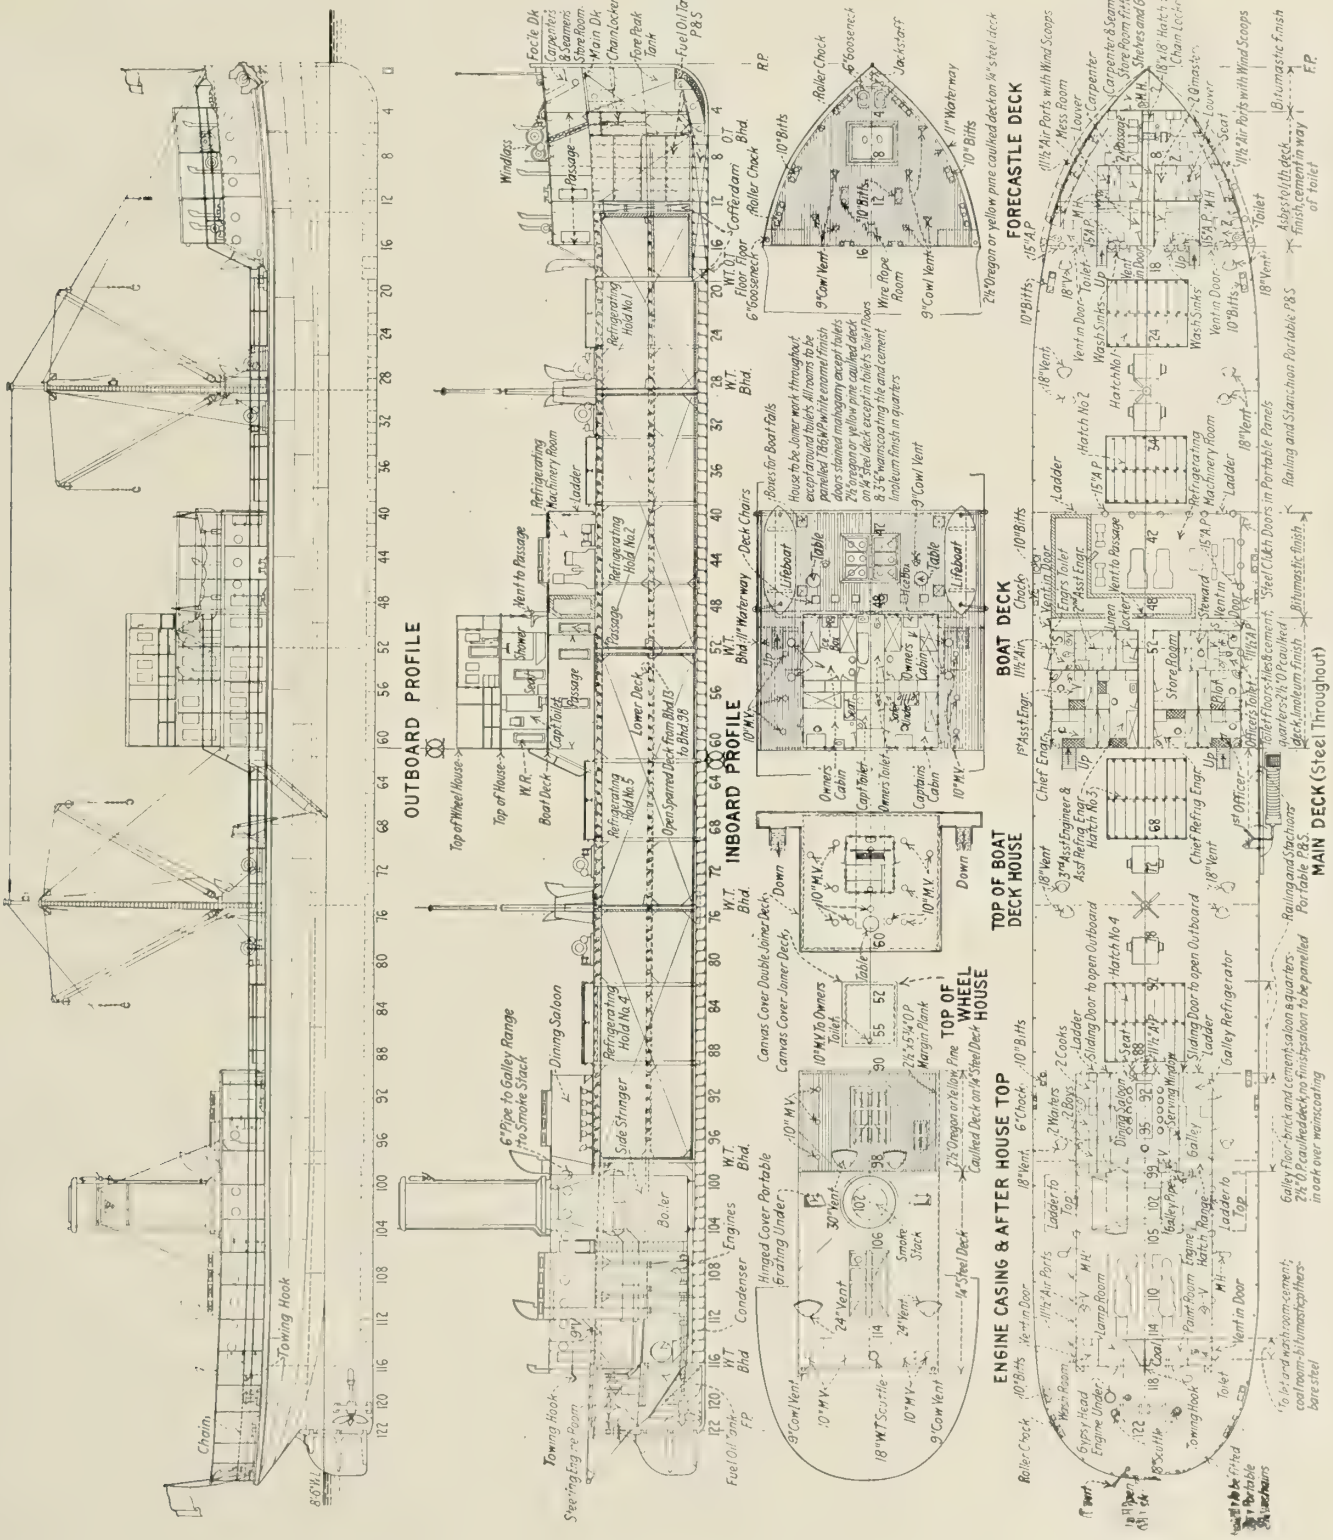
Shallow Draft Refrigerator Steamers

Vessels Built for Service on South American Rivers—The First American-Built Steamships to Fly the Paraguayan Flag

TWO twin screw shallow draft refrigerator steamers have recently been built at the Moore plant of the Bethlehem Shipbuilding Corporation at Elizabethport, N. J., for the International Products Steamship Company, of New York. These vessels are of the single deck type with a raised forecastle and are designed for service on the rivers Parana and Paraguay in South America.

Cargo Equipment

Cargo is carried in four holds which are insulated



General Arrangement Plans: Shallow Draft Refrigerator Steamer

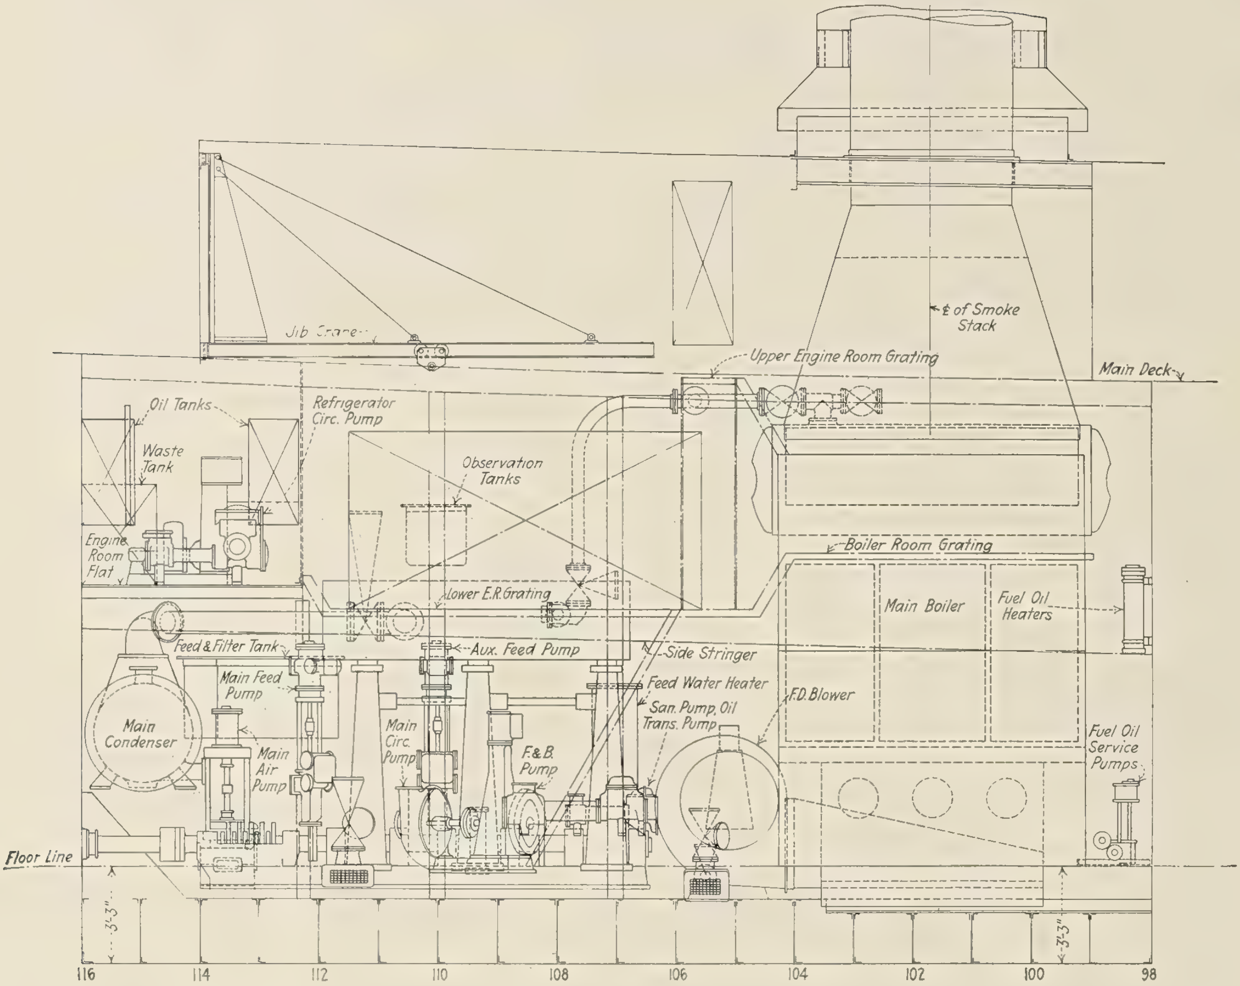
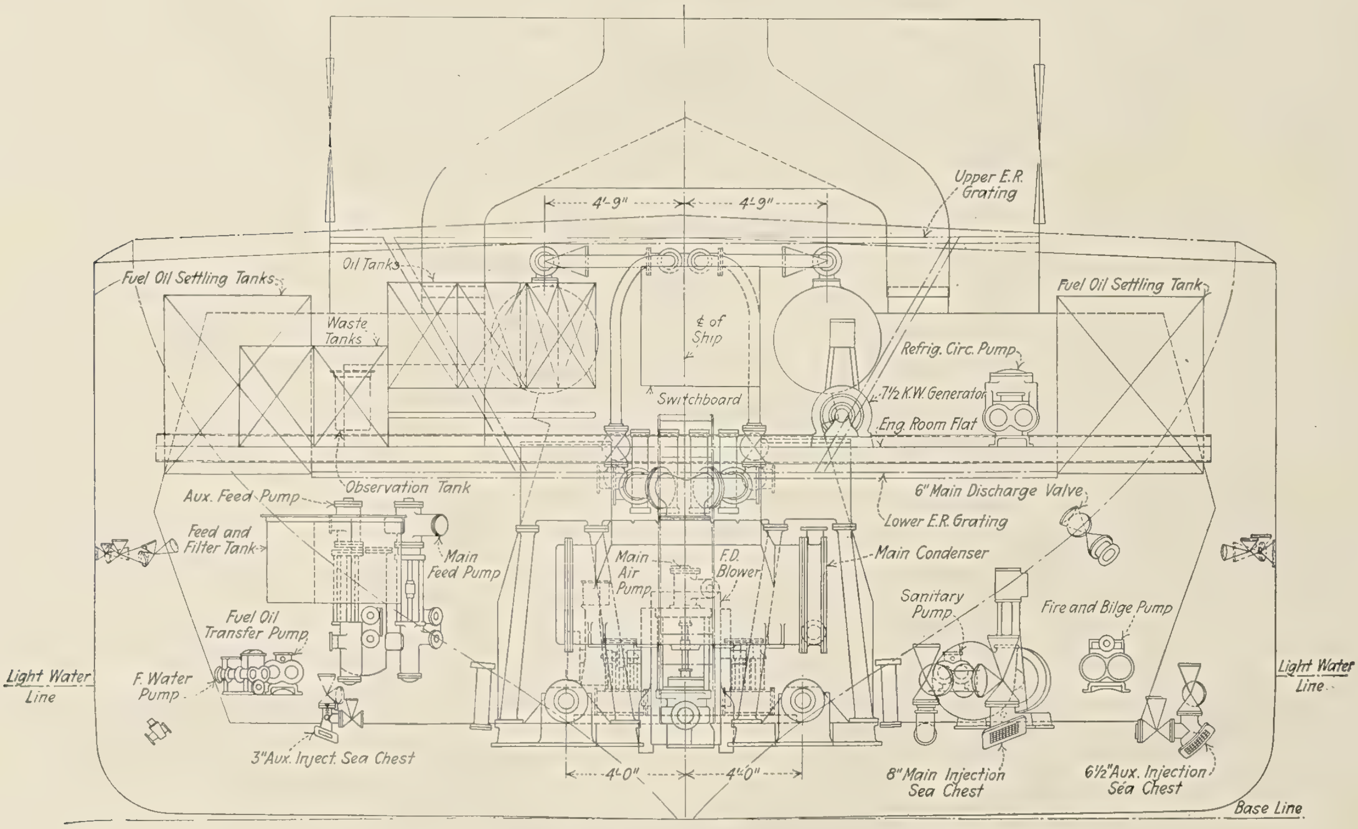
Midship Section of Shallow Draft Refrigerator Steamer



ELEVATION



CROSS SECTION AT FR. NO. 116 LOOKING FOR'D

Sections Through Engine and Boiler Rooms: Shallow Draft Refrigerator Steamer

throughout for transporting frozen or chilled meats from the company's plant at Asuncion to Buenos Aires. The refrigerating machinery consists of two 15-ton ammonia machines and is installed in a steel house on the upper deck forward of the officers' accommodation. During tests a temperature of 13 degrees F. was easily maintained in all holds.

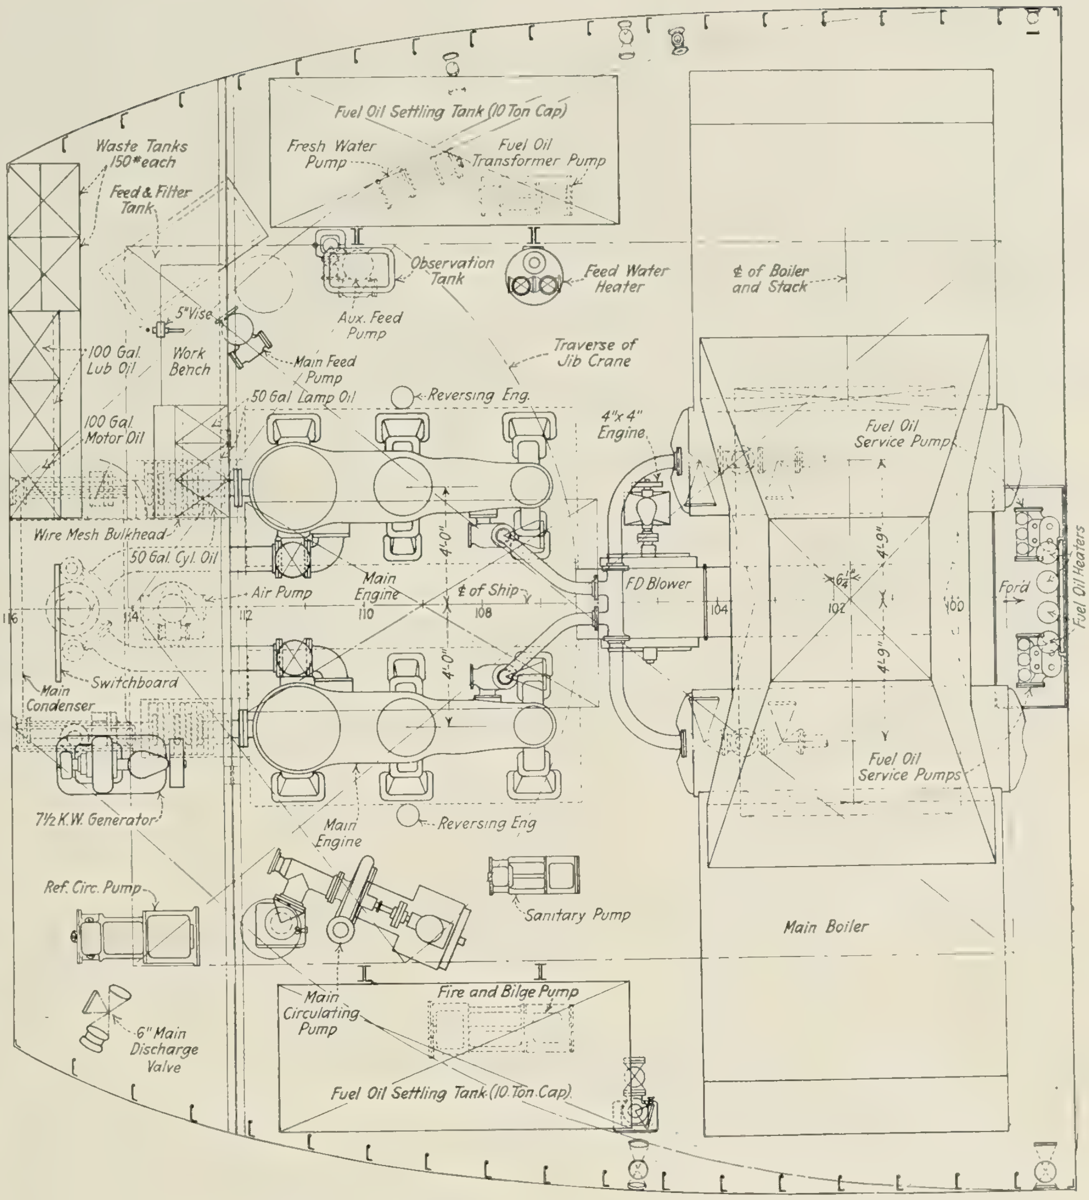
Each cargo hold is served by one winch and derrick for handling cargo overside into the ocean-going steamer or barges alongside.

Accommodations

Great care has been taken in laying out quarters to provide ample ventilation for the hot weather. Officers and engineers are quartered in a house amidships, all these rooms being outside. On top of this steel house accommodations are provided for the captain and owner. The owner's staterooms have all modern conveniences.

The crew are berthed in the raised forecastle.

A large dining saloon is provided in a steel house aft just forward of the stack, with the galley arranged on the starboard side and accommodations for the cook and steward on the port side.



Plan of Engine and Boiler Rooms: Shallow Draft Refrigerator Steamer

The propelling machinery is placed aft and consists of two triple expansion engines capable of driving the vessel at a speed of 12 miles per hour. Steam is supplied by two Babcock & Wilcox oil burning watertube boilers. The boilers are designed to work under natural draft, but forced draft has been installed to take care of any and all conditions of weather encountered on river service. Three Lodi type burners are fitted to each boiler.

These steamers are the first to be built in this or any other country to be registered under the Paraguayan flag.

Plan of Relief for Pioneer Purchasers.—The Shipping Board on February 9 announced that it had decided upon a plan of extending some relief to the "pioneer" ship purchasers, who paid or agreed to pay high prices for their tonnage, providing they will purchase for cash additional tonnage of the ships the board now has for sale, on a basis that will enable them to average down or equalize the price of their total tonnage to a basis of present replacement cost, the price to be determined in accordance with the individual circumstances existing in each case, so that the capital charge will be reduced to a figure that will enable them to compete. The pioneer purchasers acquired some 150 ships aggregating 1,000,000 tons.

Individual High-Voltage Motors Operate Successfully on Tietjen and Lang Floating Dry Dock

Although 2,400-volt motors had previously been used on floating docks using a single motor to drive all pumps on a side where geared centrifugal pumps or bucket pumps were used, the Tietjen & Lang Dry Dock Company, Hoboken, N. J., was unable to locate satisfactory references of the use of individual pump motors for voltages higher than 440 when considering new equipment in 1920 for their No. 6 dock, which had been in operation since 1900 with steam driven bucket pumps.

It was decided to change this to a complete system of electrically controlled pumps and motors. This installation, which was supervised by W. H. Reed, electrical engineer for Tietjen & Lang, has now been in service about one year and offers an interesting service record of completely satisfactory performance under unusual conditions.

Description of the Dock

The dock may be briefly described as consisting of sections or pontoons each 80 feet long with an extreme width of 111 feet. Each pontoon is divided into three compart-

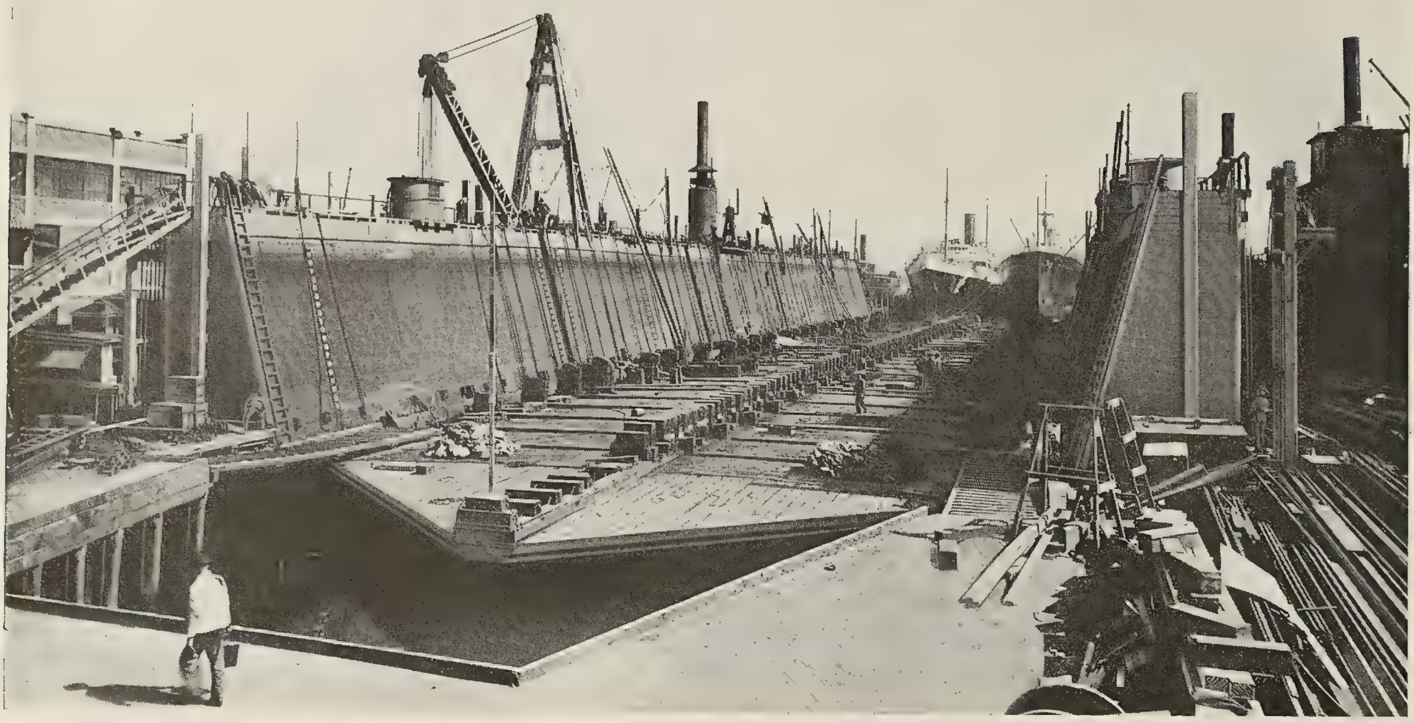


Fig. 1.—Tietjen and Lang Floating Dry Dock No. 6

ments of equal size by longitudinal bulkheads. The depth of the pontoons is 12 feet 3 inches and the height from the deck of the pontoons to the deck of the wing is 29 feet. These pontoons when placed together form a dock having an overall length, including outriggers, of 468 feet. A photograph of the dry dock is shown in Fig. 1.

The pumping equipment formerly consisted of twelve plunger pumps in each pontoon. These pumps were actuated through reduction gears by line shafts which extended along the decks of the wings, one on each side, and were driven by upright steam engines which, with their boilers and auxiliary equipment, were located on the decks of the wings of the center pontoon.

After considerable investigation of the type and form of apparatus best suited to meet the particular requirements, the pumping equipment of the Alberger Pump and Condenser Company, New York, and the electrical equipment as manufactured by the General Electric Company, Schenectady, N. Y., were selected.

The New Pumps and Motors

The pump equipment was somewhat unusual in that self-alining guide bearings on the intermediate shaft, as recommended by the manufacturer, were used with complete success in avoiding any strains on the shaft from the slight distortion occurring in a wooden dock. All pumping equipment was manufactured by the Alberger Pump and Condenser Company, one pump being located in the center compartment in each wing of each of the five sections, a total of ten pumps, each with an individual motor, permitting the utmost flexibility in control. The suction lines leading from each pump are terminated by foot valves which bring the suction within a few inches of the bottom of the pontoons. The vertical shafts of the pumps have been extended up through the wing spaces and steadied by self-alining bearings, and end in flexible couplings on a level with the decks of the wings. Just below the flexible coupling thrust bearings of the roller type are placed, which sustain the weight of the pump shafts and impellers.

The electrical equipment consists of ten General Electric vertical, squirrel cage type, 360 revolutions per minute, constant speed induction motors, designed for 75 horsepower capacity in 150 horsepower frames and for use on 2,400-volt, 2-phase, 60-cycle alternating current circuits. The motors are coupled by means of flexible couplings to the shafts of the pumps.

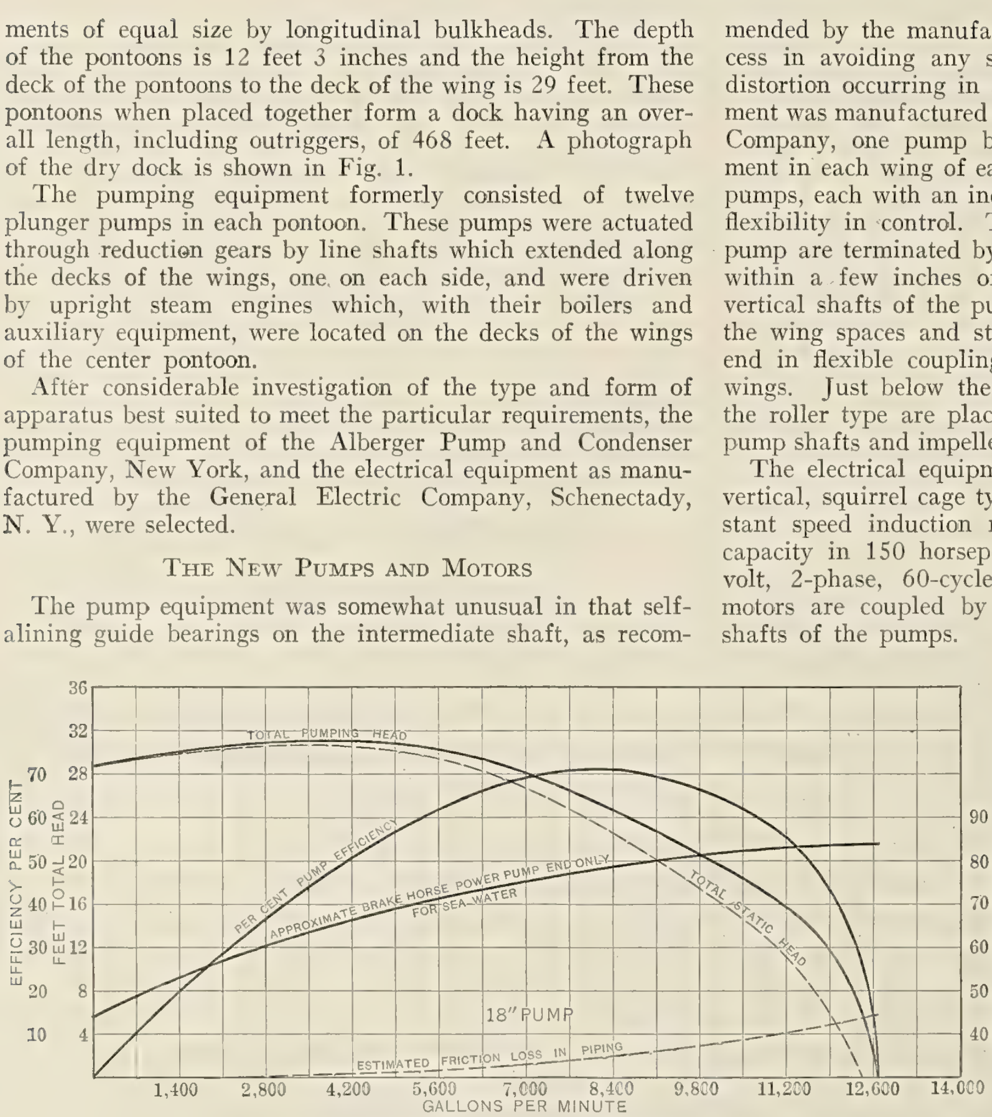

Fig. 2.—Pump Characteristic Curves

The motors are housed in wooden structures which are arranged to be heated electrically to prevent condensation through temperature changes which might otherwise affect the life of the motor insulation, due to "breathing."

Push Button Control

The control equipment for the motors has been installed in a fireproof brick structure near the head end of the dock. The equipment consists of ten push button control automatic starting compensators, each having a capacity of 75 horse-

power. These compensators are banked together to form a five-panel switchboard and have their disconnecting switches, current limiting and overload relays on the front of slate panels with the contactors and compensation coils mounted on iron pipe frame work.

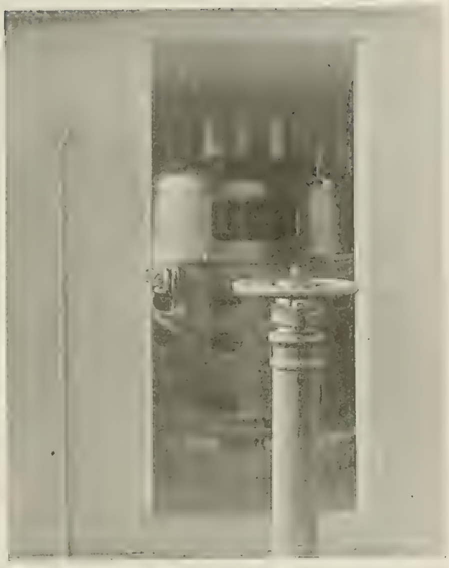

Fig. 3.—One of the Pump Motors

The push buttons controlling the starting and stopping of the motors are grouped on a slate panel which is twenty-four inches square. This is shown in Fig. 4.

When the dock is being operated the push button control panel is in charge of an operator who receives his instructions from the dock master. As the motors are of constant speed, his duties consist of starting and stopping the motors as directed. A bell system for signalling from the outboard end of the dock has been arranged for transmitting instructions from the dock. At other times the operator receives manual signals from the dock master at the inboard end of the dock.

Electric Circuit System

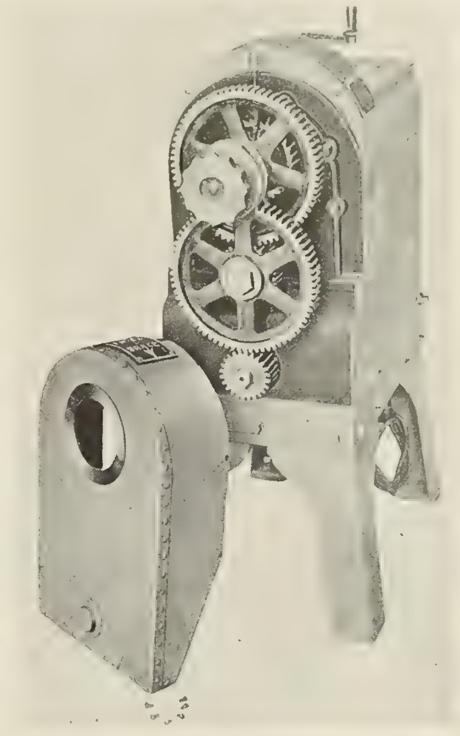
The electric circuit system can be described briefly. Each motor is on a separate circuit and all circuits originate in the control building. Iron conduits are installed from the control house of two wood structures. One of these is on the inboard end of each side of the dock. Rubber-insulated, lead-encased cables designed for 5,000 volts service are used. To make connection between the wood structure and the dock special extra flexible cable, known as "dry dock cable," is used. The circuits are carried along the outboard side of the dock in iron conduits and terminate in brass connection boxes at the ends of the section. The connection boxes are arranged with fiber spacers and filled with insulation compound. Connections between the sections are made with "dry dock cable." Particular attention has been given to making the wiring system watertight and special precautions taken to have all parts of the system "grounded" where required.

Fig. 4.—Push Button Control Board in Dock Master's Office

It is of additional interest to know that a portion of this equipment was installed during the time that the dock was still being operated by means of the old steam equipment and bucket pumps, the dock being out of service to complete the installation of the new pumps, piping and electrical equipment only sixteen calendar days until the first lift was made with the new equipment, this time being sufficient also for the removal of the old steam equipment and its pumping gear. The new equipment was put into complete service on October 26, 1920, and has operated with complete satisfaction.

Rotary Brake Sounding Machine for Depths Up to 100 Fathoms

SOUNDINGS up to a depth of 100 fathoms without decreasing the speed of a vessel or losing the lead and wire have been made with a new Lietz rotary brake type sounding machine which consists of a mechanical sounding device driven by a General Electric one horsepower motor. A special feature of the machine, which is an improved type of a former design, is the brake mechanism which consists of a mounted shaft having a hollow portion on which the reel for the wire revolves. The brake clutch is rigidly mounted and is operated through the hollow portion of the shaft by means of a screw which, engaging with the rolling members in the hollow portion of the shaft, causes expansion and contraction of the brake clutch which rotates with the reel and shaft while winding in.



Lietz Rotary Brake Sounding Machine

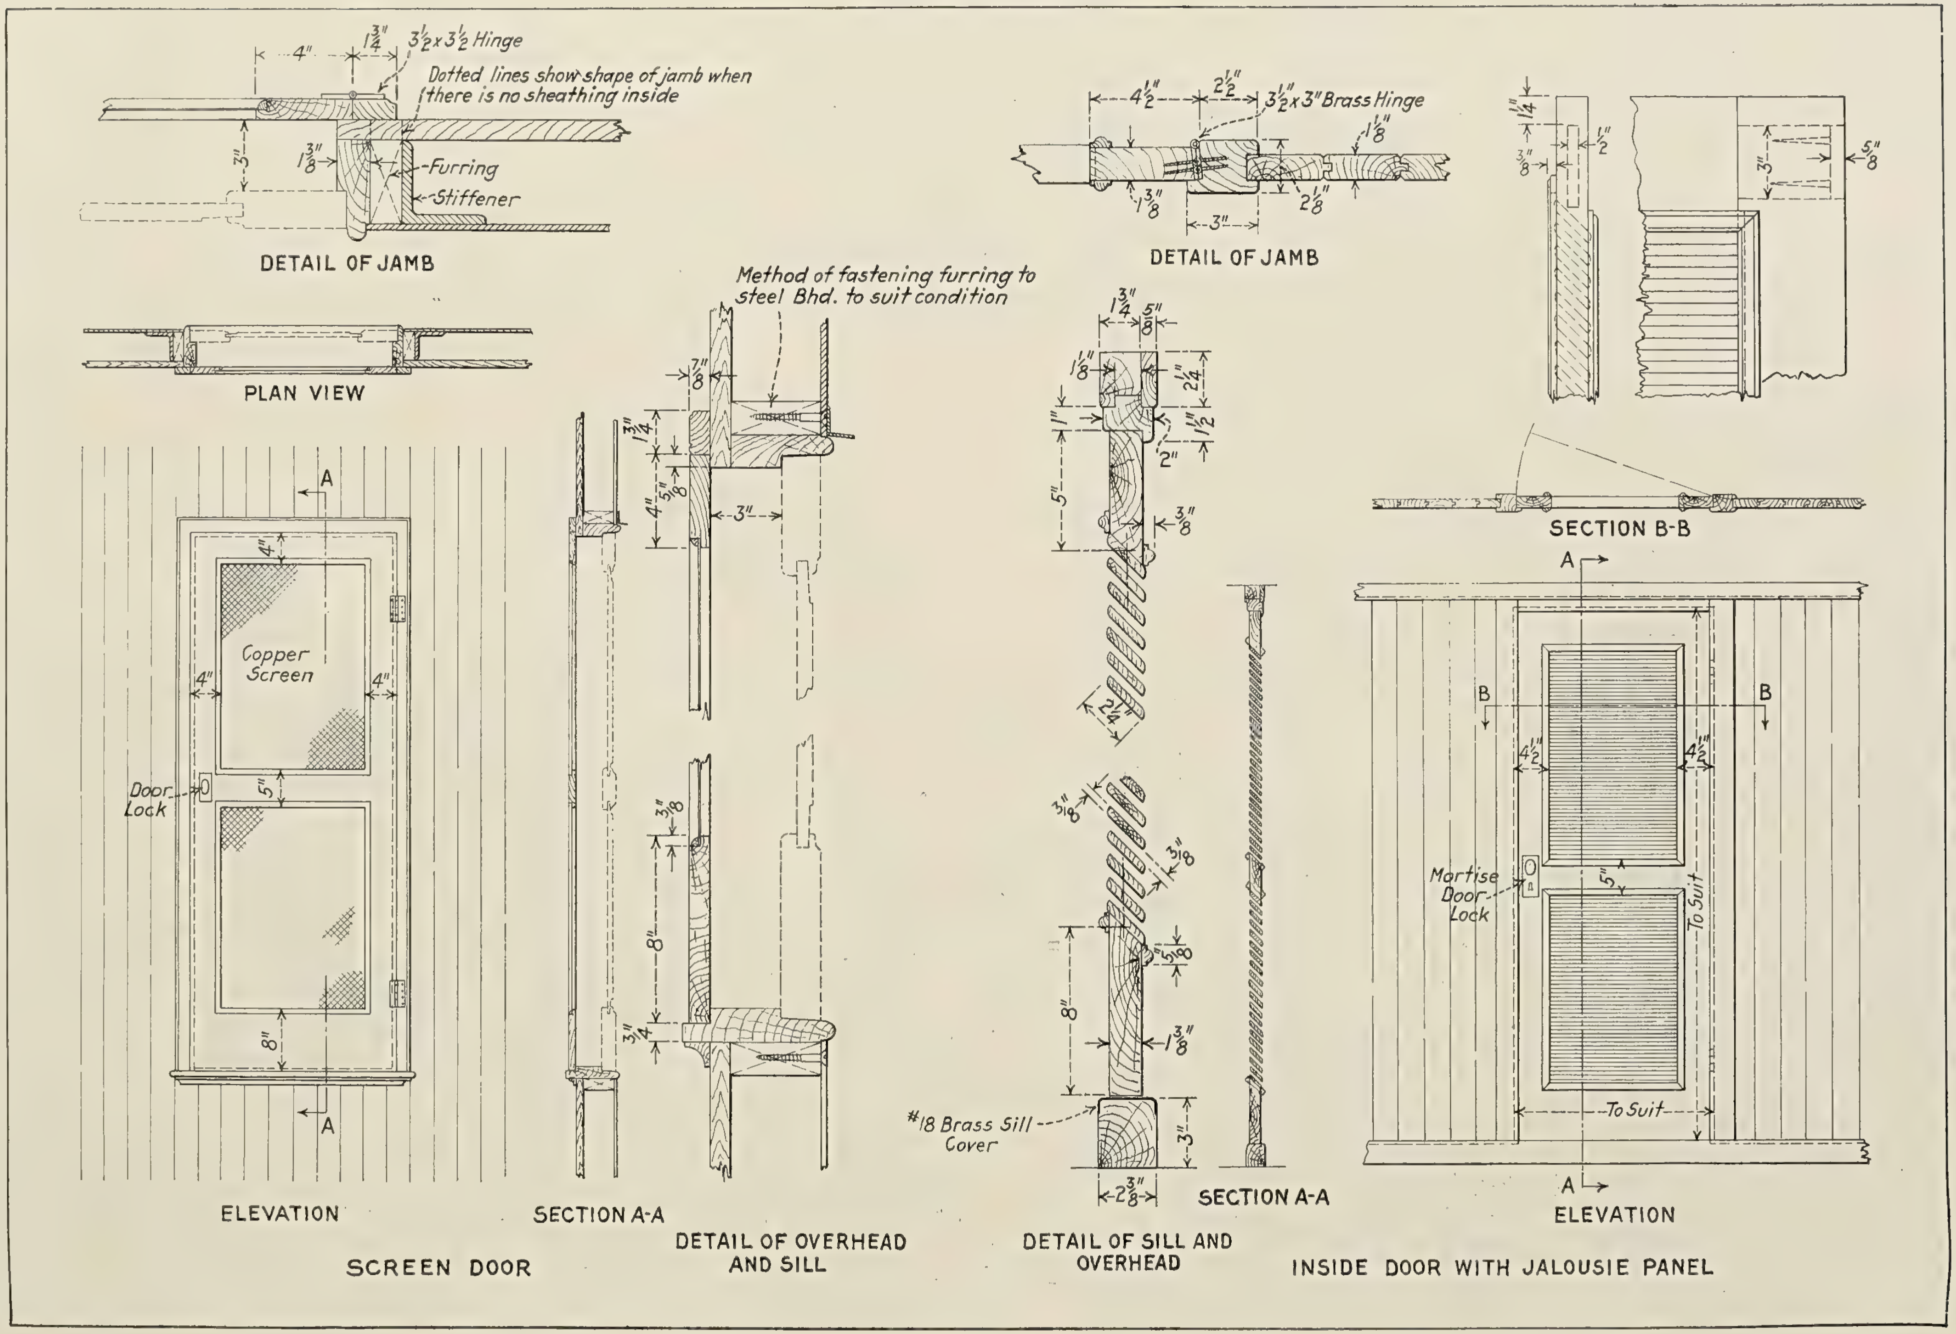
The braking mechanism is actuated by a brake wheel on the outside of the casing and acts on the reel gradually, preventing its stopping suddenly with the consequent loss of the wire and lead. An indicator is located on the case near the brake wheel which shows which way to turn it to free the reel and let out the wire or to brake the wheel for winding.

Although normally designed for operation by a one horsepower motor, the device is arranged so that it can be worked manually if desired. In this case disconnecting the motor from the gearing is unnecessary as the motor armature acts as a flywheel. All parts of the machine are easily accessible for inspection or repair.

Munson Line Gets New Ships.—A. J. Frey, vice-president of the United States Shipping Board Emergency Fleet Corporation, in charge of operation, has announced that the *Pan-American,* formerly the *Palmetto State,* has successfully completed her trial trip and has been delivered to the Munson Line of New York, which will operate her in the South American service. Mr. Frey also announced that the *Western World,* formerly the *Nutmeg State,* now in process of completion at the Sparrows Point yard of the Bethlehem Shipbuilding Corporation, will also be delivered to the Munson Line the last week in April, to be placed in the same berth. With the completion of this vessel the Shipping Board construction program will come to an end.

Ship Joiner Plans

Inside Doors



Munson Liner Munargo, Built for Passenger and Freight Service to the West Indies

New Munson Liner Munargo Goes Into Service

Fifteen-Knot Geared Turbine Passenger Steamer, Built by New York Shipbuilding Corporation, Added to Munson Fleet

THE latest addition to the increasing fleet of the Munson Steamship Line, New York, is the passenger and cargo ship *Munargo,* recently completed at the plant of the New York Shipbuilding Corporation, Camden, N. J. The new vessel is 414 feet long and 57 feet 6 inches beam, with a draft of 23 feet 8 inches. She has accommodations for 185 first class, 60 second class, and 52 third class passengers with a crew of 119, and in addition has a cargo capacity of 2,000 tons.

Driven by reduction geared turbines of 5,800 horsepower, supplied with steam from five boilers, fired by fuel oil, the *Munargo* will maintain a speed of 15½ knots in service. The boilers are of the Scotch type and the turbines of the Parsons type driving the propeller through DeLaval reduction gears.

The staterooms are replete in modern conveniences, including specially designed dressing tables, beds, electric fans, etc. The old type of berth has been largely superseded by specially designed enamelled beds. The suite rooms on the promenade deck are finished in a light natural grey toned to match the hangings while the trim is either mahogany or French walnut, according to the period of the furnishings. The suite rooms, as well as the special rooms on the bridge deck, have their own private bath rooms connecting.

The public rooms are numerous, light, airy and exquisitely finished. They include a social hall, lounge and music room, smoking room, library and writing rooms, entrances and galleries. A sun and dancing deck for first class passengers has been provided on the boat deck over the smoking room.

The dining saloon is located on the shelter deck, over the center of which is located a large dome and light well opening into the music room. Tables are arranged for small and large parties. Specially designed buffets, etc., blend harmoniously with the surroundings.

Lounge

Smoking Room

An extensive refrigeration plant is installed with separate compartments for meat, fish, vegetables, butter and eggs, etc., and is of ample capacity for any emergency.

Ventilation and heating throughout the ship have been cared for in a very complete manner, insuring comfort at all times whether in the intense heat of the tropics or the extreme cold of the North Atlantic.

Separate complete hospitals are provided for passengers and crew, fitted with modern appliances.

Accommodations for the second and third class passengers are all aft and far surpass the accommodations furnished in older ships. Public rooms, including a social hall, smoking and music rooms, are provided to insure comfort at all times.

Accommodations for the officers and crew are for the most part located on the boat deck with enclosed companion ways for access, so there is no need of coming in contact with the passengers.

The ship has been built on the transverse system of framing and to take the highest class in the American Bureau of Shipping and Lloyd's Register. The *Munargo* starts her career as an oil burner, but is so designed that conversion to coal will not be a difficult matter should it become desirable.

Dining Room

Together with the other additions to the Munson Line this class of ship will go a long way towards eliminating the absence of passenger vessels under our flag in the West India and South Atlantic services.

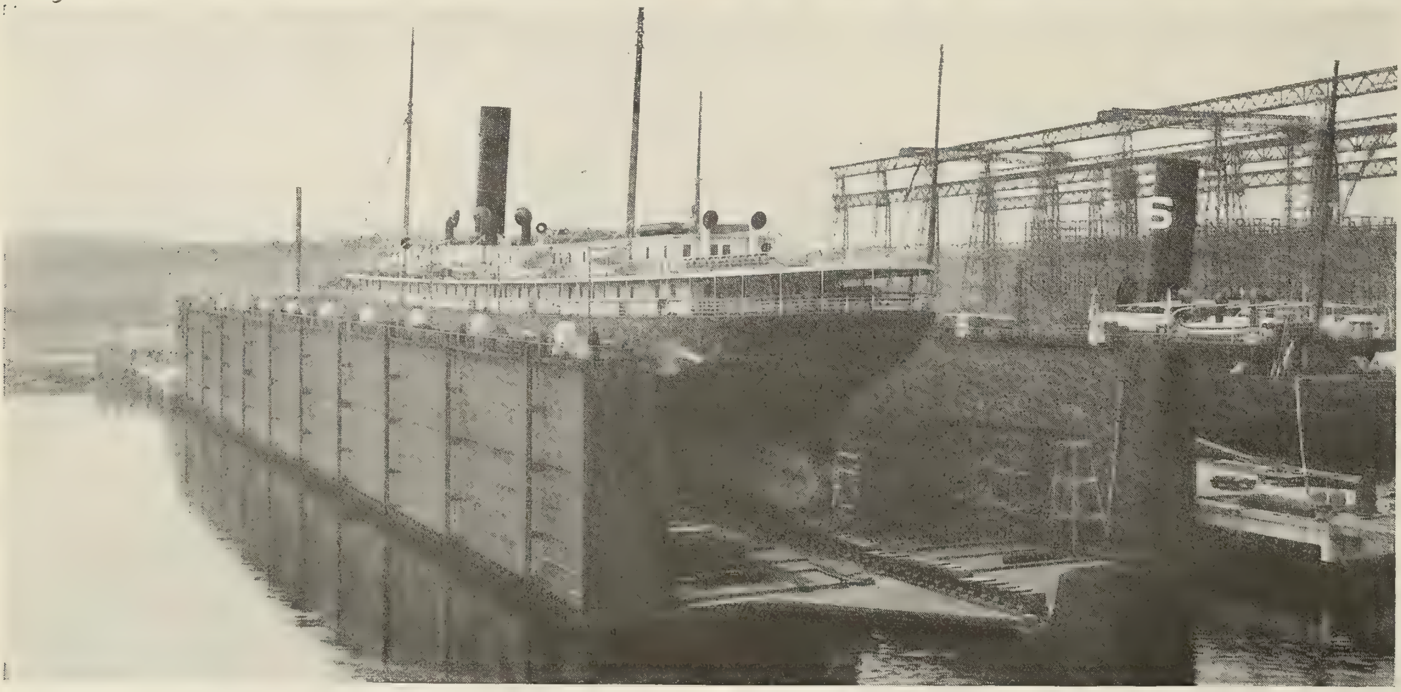
New Floating Dry Dock at Fore River Shipyard

Bethlehem Shipbuilding Corporation, Ltd., Installs a 10,000-Ton Dry Dock of the Donnelly Type at Its New England Plant

THE only floating dry dock on the Atlantic coast between Halifax and New York City is located at the Fore River plant of the Bethlehem Shipbuilding Corporation, Ltd., Quincy, Mass. Supplemented by the large machine, boiler and plate shops of the shipbuilding plant, this dock offers excellent facilities for serving the port of Boston.

The dry dock is of the well-known Donnelly type and has a capacity of 10,000 tons. In order to give berthing space to vessels requiring attention without the necessity of docking, a repair basin is provided adjoining the dock. Transportation facilities and crane service for vessels in either the dock or repair basin are carried on a mooring pier that is 50 feet wide and 616 feet long, measured from the bulkhead line.

On this pier are located two standard gage railroad tracks and the track for a 15-ton tower crane. The standard gage tracks are imbedded in the concrete in order to leave a clear roadway for motor trucks and other vehicles. The third rail for the crane and the pipe lines are placed in trenches along the sides of the pier, so arranged as to make T-beams of the adjoining crane stringers. In order to allow for shrinkage and expansion due to changes in temperature, two transverse expansion joints are provided in the deck of the mooring pier. Projections of the sliding floor beams, which engage corresponding recesses in the stationary floor beams, prevent the pier from getting out of alinement. The columns supporting the mooring pier located nearest the shore rest on piles



Donnelly Type Floating Dry Dock of 10,000 Tons Lifting Capacity at the Fore River Shipyard

while the columns located in deep water rest on bed rock.

The dry dock consists of ten wooden pontoons under continuous steel side wings. A timber outrigger projects from each end pontoon. Two shore bridges leading from the head pier to the deck give access to the latter, and a swinging ramp connects the port wing wall to a steel landing tower near its in-shore end. The vertical motion of the dock due to the tides and when submerging or rising is guided by side and end moorings anchored to the concrete piers.

Each pontoon is 116 feet wide and 40 feet 10 inches long. The wing walls are 418 feet 9 inches long and 35 feet high, tapering on the inside from a width of 13 feet at the bottom to 8 feet 6 inches at the top. Connection between the pontoons and wing walls is made by means of links. Each link engages two pins, one of which is attached to the pontoon and the other to the wing wall.

The pumps for discharging the water from the pontoons and wings when the dock is raised are electrically operated from a control house on shore. Electrical connections are such that by means of individual switches the pumps of any pontoon can be operated independently of the others or, by means of a master switch, the pumps of all pontoons can be operated simultaneously.

This feature provides means whereby the stresses in the vessel being docked may be equalized by utilizing the individual control and bringing decreased or increased upward pressure to bear on certain pontoons, as required.

The first vessel docked was the *Miller County*, on February 12, 1921. The completion of the dock has filled a long-felt want in providing vessels entering the port of Boston with convenient and modern facilities for having repairs made to hull or machinery.

The British Shipbreaking Industry

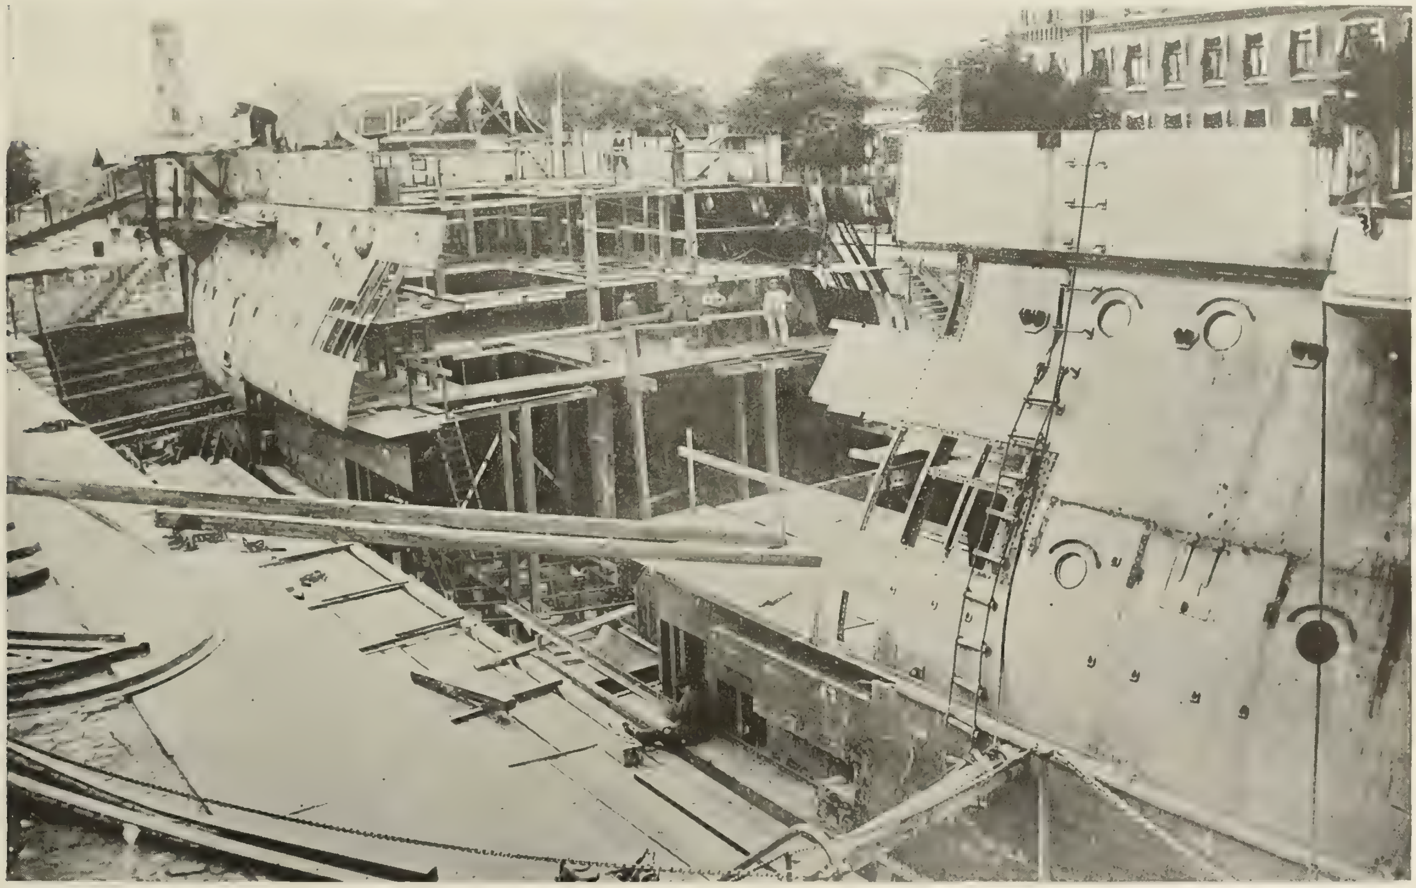
Non-Ferrous Metals Are Most Valuable—Hardwoods Sold for Furniture—Steel Cut Up for Melting

By Our London Correspondent

THE shipbreaking yards of the United Kingdom are at the present time veritable hives of industry. During the war, when tonnage was so precious, every vessel, no matter what its age or condition, was able to secure its freight and the shipbreaking trade fell into abeyance, but, with the cessation of hostilities and the flooding of the market with new vessels, the industry entered into its own, with the result that probably every shipbreaking yard in the country has enough work to keep it going at all events for the current year. And in the background looms the Washington Conference, with its gigantic scrapping of warships to add to the mercantile marine break-up.

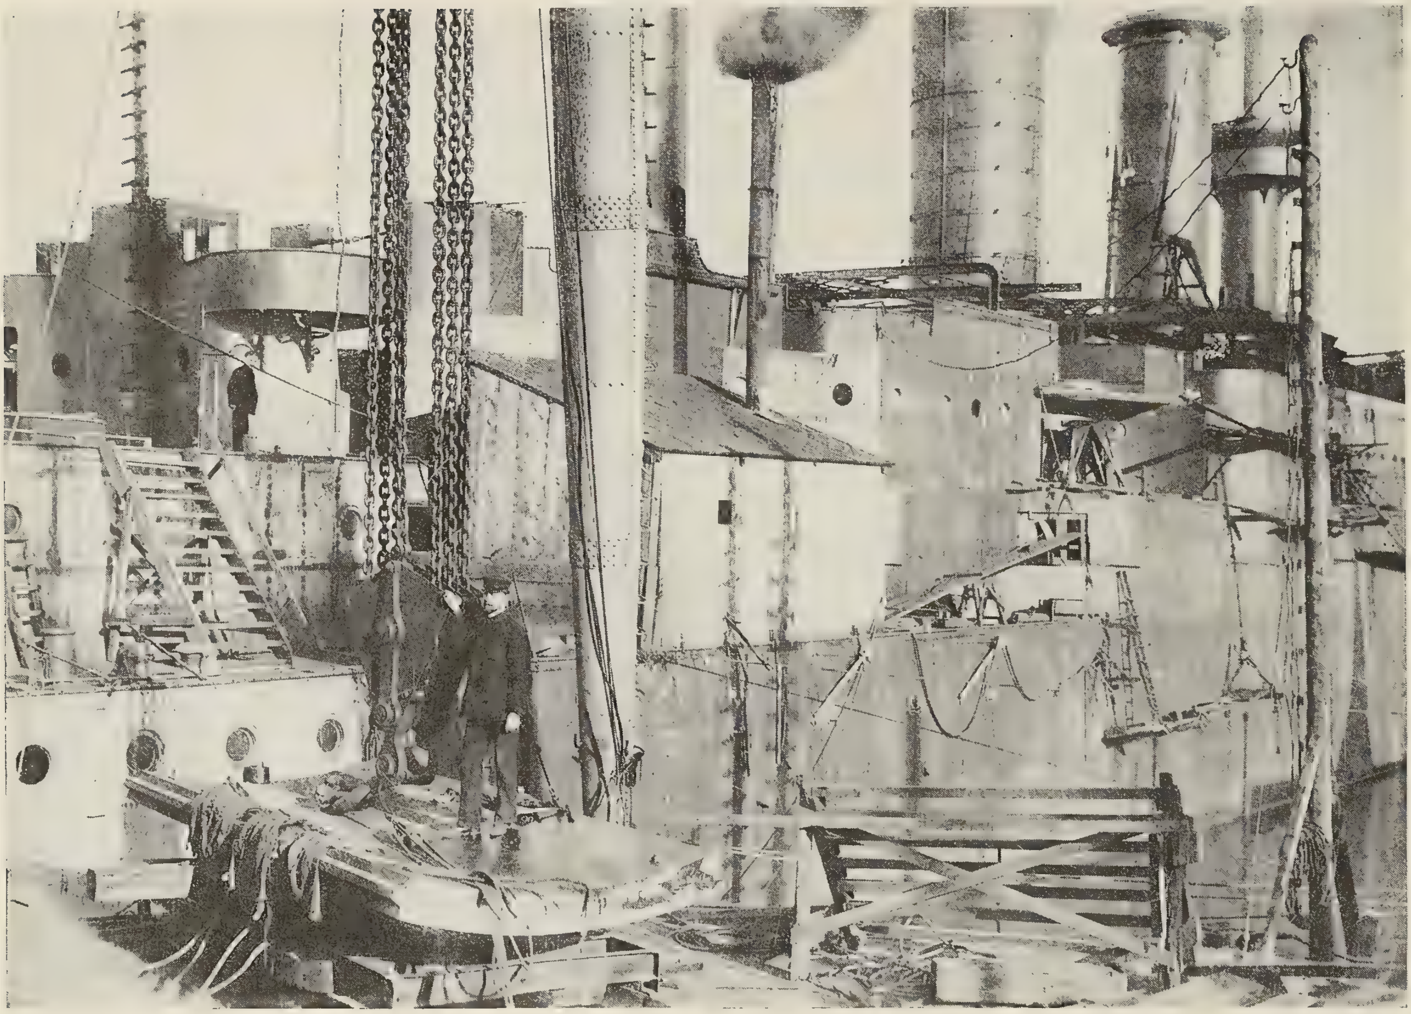
Process Adopted by Thos. W. Ward, Limited

One firm, the introduction of whose name into an article of this description needs no apology, is Thos. W. Ward, Lim-



(Photograph copyright by Kadel & Herbert News Service, N. Y.)

Breaking Up a German Warship in a Dry Dock



(*Photograph copyright by Kadel & Herbert News Service, N. Y.*)

Removing Armor Plate from German Warship While Afloat

ited, of Sheffield. The process adopted by Messrs. Ward in destroying a warship is a highly developed one. The first operation is to remove the deck fittings, and then comes the difficult operation of taking up the deck. At this point I should make it clear that it is not the practice to take out the engines and boilers in the early stages of breaking up, this being left until the upper portions of the vessel have been dealt with. The engines and boilers are thus easier to get at. For the deck lifting operation, oxygen and acetylene are combined to eject from a pipe a flame of great intensity. Large squares are cut out of the decks and swung by crane on to the quay. With the disappearance of the decks, the engines and machinery come to view and with wrench and hammer the breakers detach large portions for the crane to lift clear. Then come the compartments, the officers' quarters, the boilers and the shaft. Having come to the empty shell, the oxy-acetylene flame gets to work again, and the sides of the hull are cut into squares. On the quay, steam shears cut pieces of steel into sizes that will fit the furnaces for which they are intended, most of the steel finding its way to South Wales, where it is melted down.

A Stripping Method

The method adopted by another well-known firm in demolishing vessels is to strip them of their metal, machinery, fittings and equipment, but, before selling the metal, this is cut up into crucible sizes, as there is a more ready market. The teakwood is removed very carefully and is usually sold to people in the furnishing line. With regard to the hulk, this is also cut up into furnace size by means of the oxy-acetylene burning plant. At present, owing to the slump in the scrap trade, this is hardly a paying proposition but a little improvement on current prices would certainly make it so.

A firm which does not break up iron and steel ships, but limits its work to old wooden battleships, tows them from the dockyards to its shipbreaking wharf, where they are demolished, the timber being converted into whatever it will make. Americans, I am told, are buyers of old ship oak for building purposes, where the antique design is carried in this material.

Pitfalls Await the Inexperienced

The pitfalls for those about to establish shipbreaking businesses are many, even for the wary, and the advice of Mr. Lawrence Levy, one of the most experienced men in the shipbreaking industry in Great Britain, is, similarly to that of *Punch* to those about to marry—"Don't!" *En passant,* it is interesting to note that the company of which Mr. Levy is managing director—the Shipbreaking Company, Limited, of London, Swansea, etc.—has dealt with all types of vessels during the past quarter of a century, and since the armistice has undertaken the demolition of no fewer than twenty-five ex-German submarines, in addition, of course, to other craft.

To those embarking on breaking up submarines Mr. Levy tells me that the first essential point to bear in mind is to clear the vessels absolutely of oil—whether fuel or lubricating. His firm strips the boats to their very bottoms, for the simple reason that, if the steel were not stripped entirely, a considerable quantity of metal would go to waste. It is not

the custom to take the hulk out and sink it; but, by the time the breakers have achieved their work at the wharf the portion of the vessel remaining is negligible and it is then finished on the beach. In the big battleships there is, it is true, a certain amount of teak and so on to be salvaged but in the majority of cases there is little of real value beyond the scrap non-ferrous metals. Mr. Levy emphasizes that, when engaged on submarines in docks, it is advisable to have somebody on board—as, for example, an ex-naval officer—to supervise the dismantling.

Wages an Important Factor

As I have indicated, Mr. Levy does not regard the profession of shipbreaking as a means to easy and plenteous wealth, more particularly at the present time when wages and most other charges are high and the value of the metals obtained stands at only a tithe of their figure during the war, consequent on the trade depression and the superabundance of new metal at low costs. With regard to wages, Mr. Levy instances that, whereas in this country shipbreakers' employees receive about £3 for a week of forty-seven hours, in France the corresponding wage is equivalent, at the present rate of exchange, to about seven shillings for a ten-hour day. The wages cost alone in Great Britain represent, therefore, nearly double those just across the English channel; so the value of the steel portion of the vessels does not cover the cost of recovering the steel scrap.

In view of the depreciated rate of exchange in Germany, it is scarcely surprising that some of the contracts in the hands of British shipbreakers have been transferred to German yards, to the mutual advantage of the contractors and sub-contractors.

Motorship Building in Europe

Motorships Without Auxiliary Compressors—Geared Diesel Vessels—New Types of Engines

By Our Special London Correspondent

SCARCELY a month passes without bringing forth some striking innovation in motorship machinery. Having apparently convinced shipowners that the modern marine oil engine is equally as reliable as a steam plant, manufacturers are tending towards simplified construction, mainly with the idea of reducing the cost of building. At present the machinery of a motorship costs some 20 to 25 percent more than that of a corresponding steamer equipped with reciprocating engines and shipowners are demanding that this somewhat considerable difference should be reduced. So far as can at present be gathered, the tendency will be towards simplification and therefore cheapening of auxiliary machinery, the development of compressorless Diesel engines and more efficient standardization in manufacture. By this means various firms are hopeful that within the next two or three years, the engine room installation of a motor vessel will cost no more than that of a steamer.

An example of this line of thought is seen in the motorship *Handicap*, which sailed on her maiden voyage at the beginning of the year. The propelling plant of this vessel is in any case a noteworthy installation, embodying as it does the first examples of the new Sulzer two-stroke engine using turbo scavenging blowers instead of large piston pumps driven direct from the engine crankshaft. A fully illustrated description of this arrangement was recently published in MARINE ENGINEERING AND SHIPPING AGE and need not be repeated. It may, however, be remarked, surprising as it would appear, that by installing two turbo blowers in the engine room each driven by a 150 brake horsepower electric motor, there is an actual saving in weight as compared with similar engines driving their own scavenging air pumps as are usually installed.

These turbo blowers occupy very little space, being arranged in enclosed compartments in the wings of the vessel and the engines, being naturally reduced in length by the elimination of the scavenging pump, allow of an engine room

1,350-Ton Single Screw Motorship Balzac, a New Type for Service in European Waters

probably shorter than that of any vessel equipped with machinery of equal power (2,700 brake horsepower).

What is most remarkable in this ship, however, is that there is no auxiliary air compressor. The air required for starting and maneuvering purposes is supplied wholly from the blast injection compressors on the main engines and on those used for driving the dynamos. This system has never previously been employed and although the cost of one or two electrically driven compressors is avoided it is somewhat doubtful whether the plan is desirable. The builders claim that there is plenty of compressed air available above that required for the fuel injection, and that it is unnecessary to install two further maneuvering compressors. It is improbable that any British shipowner would agree to take the risk thus involved, the vessel being Norwegian owned. Indeed it is somewhat doubtful whether an installation of this sort would pass Lloyds. Nevertheless, if it is perfectly successful, it may have a far reaching effect for the result is an engine room of extreme simplicity, comparing favorably with most other installations.

Geared Diesel Ship for the Hamburg-American Line

Whether there is a future for the geared Diesel ship as some shipbuilders and shipowners appear to imagine is a controversial question and the Hamburg-American Line has shown some temerity in putting two such vessels in service. The second ship, the *Munsterland*, was completed early in February. She is exactly similar to the first vessel of this class, being 465 feet in length and having a deadweight capacity of nearly 11,000 tons. There are two ten cylinder four cycle engines installed, which run at 230 revolutions per minute although originally designed for a much higher speed. They develop 1,650 brake horsepower each, and drive the propellers through a reduction gear of 2.7 to 1 so that the propellers turn at 85 revolutions per minute.

Whatever may be said regarding the reliability of engines of this type the Hamburg-American Line has undoubtedly acquired motorships costing less than any other vessel of their size built during the past few years. It is understood that the engines, which were originally designed for large German submarines, were obtained at a very low figure and, owing to their lightness, the deadweight capacity of the vessels is larger than almost any others of corresponding dimensions.

New Types of Diesel Engines

Unanimity of Diesel engine design seems as far off as ever. Several new types have been brought out during the past month or two. The first Beardmore Tosi engine has been completed and installed in the 2,500-ton motorship *Pinzon*. This motor is noteworthy chiefly from the adoption of a combined inlet and exhaust valve which, it is claimed, overcomes exhaust valve trouble and avoids the frequent cleaning necessitated with the ordinary design.

Another new engine is a 1,200 brake horsepower set, constructed by the Atlas Diesel Company of Stockholm, of the two cycle type which goes one better than the Sulzer and provides a design in which each cylinder cover has only one valve, namely the fuel valve. Scavenging air enters, and the exhaust gases are discharged, through ports in the cylinder liner and starting is effected by enclosing the bottom of the cylinder and causing the lower section of the cylinder below the piston to act as a maneuvering engine when starting and a scavenging pump when the motor is running. This naturally involves a somewhat complicated system of air distribution and it is questionable whether the system is an improvement upon the Sulzer method with the starting valve in the cylinder cover. The scavenging air supplied in this way from the six working cylinders below the piston is not sufficient for the requirements of the engine so that there is an additional scavenging pump driven by a beam lever from one of the crossheads. This engine has just passed through its trials for installation in a single screw 5,000-ton cargo vessel.

Another German Design

The third new type is that developed by the Deutsche Werke in Kiel at the old Royal Naval Dockyard. The first examples of the engine are about to be installed in an 8,000-ton motor tank ship. Like so many other German builders, the Deutsche Werke decided to adopt the four-cycle principle and there is little that is original in the construction except that each engine is made self-contained with its air compressor, lubricating oil, circulating water and general service pumps, driven by levers off the engine crossheads. This again has been adopted with the idea of reducing the cost of construction and of minimizing the number of auxiliaries in the engine room.

Something of a revolution is predicted in Diesel engine construction in the near future although a great deal of secrecy is observed at the present time. A new engine is being built by two or three of the leading Continental manufacturers, the main advantage of which is the elimination of the compressor. This is effected, not by employing mechanical injection at very high pressure as has already been adopted in several successful engines, but by another device which enables the fuel to be pumped through the fuel valve at a pressure of only a few pounds per square inch. It is expected that the new design will be placed on the market in the very near future and a very considerable reduction in cost of construction compared with the air blast type is anticipated.

14,000-Ton Motorship

The Royal Mail Steam Packet Company has just taken delivery of its first motorship, a vessel of 14,000 tons deadweight named *Lochkatrine*. This is the largest type of oil engined vessel afloat, equipped with twin screw machinery of 6,400 horsepower built by Harland and Wolff of the usual Burmeister and Wain design. The fuel consumption of this ship when carrying a full cargo at a speed of about 13½ knots is about 20 tons daily.

Another interesting new vessel is the *Dominion Miller*, built by Doxfords for the Furness Withy Company and representing the second ship equipped with the remarkable 3,000 horsepower Doxford opposed piston oil engine. Incidentally it may be remarked that the manufacturers of this type are so satisfied with its performance that they are now quoting for single engines up to 6,000 brake horsepower. In order to demonstrate that the opposed piston engine can run on boiler fuel oil a seven days' trial was recently made, using Mexican fuel oil (.95 specific gravity), the results of which were, it is stated, completely satisfactory and the fuel consumption no higher than when utilizing high grade Diesel oil.

Combination Portable Drill and Grinder

A NEW portable combination machine for hand drilling and grinding operations has been developed by the Wodack Electric Tool Corporation, Chicago, Ill. The tool is so designed that the motor has the correct speed for both drilling and grinding. The drilling capacity is ⅛-inch to ⅝-inch holes in steel and when used as a grinder it is fitted with a 6-inch by ¾-inch wheel. The complete weight of the machine is 18 pounds and the motor under service develops ½ horsepower.

Boiler Scale Investigation.—The Bureau of Mines has undertaken, at the Pittsburgh Experiment Station, an investigation of the mechanism of scale formation in steam boilers. The object of the investigation is to determine if the character of the precipitates forming in boilers may be made to assume a form in which they do not attach themselves to the walls, and also to ascertain if the material in the boiler wall exercises any influence.

Effect of Vacuum Upon Economy in Marine Practice*

Vessel's Income Depends Upon Securing Maximum Ton Miles Per Ton of Fuel, Which Is Largely Influenced by the Vacuum Obtained

By Frank V. Smith†

As the income of a ship depends upon ton miles, it must also depend upon the speed of the vessel and the number of days actually at sea. Any condition that delays a ship in port, or delays its speed at sea, means just so many less ton miles and, therefore, less income.

An engineer is very apt to say that he cannot see that his job affects the income of a ship in any way and that the running of the ship, that is the executive end of it, is all done in the office and, therefore, all he has to do is to follow orders. We will consider one item to bring out more clearly why the engineer of a ship has a great responsibility and in what way he holds in the palm of his hand the making or breaking of the merchant marine.

Consider a turbine ship of the type that we are most familiar with—a 2,500 shaft horsepower turbine with double reduction gears. The power derived from a pound of steam depends upon the initial steam conditions, that is, pressure and superheat, or, taking the two items collectively, the total heat of the steam and the final pressure or vacuum. The difference in the heat content of the steam in its initial and final state, therefore, becomes the direct measurement of power. In a theoretical sense it does not matter what the initial and final pressures are as long as the same definite quantity of heat has been utilized and converted into power per pound of steam.

The steam consumption of a turbine, regardless of the power extracted by the turbine itself, is dependent upon the initial pressure, superheat and nozzle area. If we assume a case where the power derived from the same quantity of steam at the same initial pressure differs on account of the difference in vacuum obtained and know definitely how this power affects the speed of the ship, it presents an interesting analysis, for it directly affects the ton miles per year and, therefore, the income.

One Inch of Vacuum Equals About 75 Pounds of Initial Pressure

One inch of vacuum will roughly amount to from five to seven percent of the fuel, but do not think for one minute that this additional fuel is being used to make up for the loss in vacuum for it is not. With the loss in vacuum the fuel consumption is remaining the same, for the steam consumption is the same and will remain the same unless the initial pressure is increased to make up for the deficiency in vacuum so that the same pound of steam could liberate the same amount of heat. This, to my knowledge, has never been done on any of our ships. To make up for a loss of even one inch of vacuum it would be necessary to raise the initial pressure 75 pounds or more, and it is not at all likely that any engineer who has been in the habit of carrying a boiler pressure of 210 pounds gage would immediately upon the loss of one inch of vacuum raise the boiler pressure to almost 300 pounds. The fuel consumption is remaining the same as long as the initial pressure is the same and it simply means that there has been less power liberated for the same amount of fuel. Figured in terms of fuel per shaft horsepower hour, facts of this kind soon become evident in the analysis of the various reports.

Generally speaking, a typical cargo vessel, in order to pay operating expenses, with only a fair return on the capital investment, must average from 60 to 70 percent of a cargo when operating from 35,000 to 40,000 miles per year. Under this condition the average income should be, when figured on a knot basis, from $11.00 to $14.00 per knot, varying slightly with the valuation of the vessel. As a basis for future estimates on the value of vacuum, power and speed on a ship of from 7,800 to 9,000 tons deadweight carrying capacity a very fair average of $13.00 per knot will be used.

Assuming the same steam consumption, pressure and superheat and, therefore, the same fuel consumption, a variation in the vacuum will affect the power, speed and knots per year approximately as shown in the following table:

Effect of Vacuum

Initial pressure, 200 pounds, gage; 75 degrees F., superheat.
No. of nozzles open, 12.
Assumptions: (a) Designed speed of ship, 11.5 knots at 2,500 shaft horsepower.
(b) Value of ship at sea, $3,600 per day or $13.00 per knot.

Vacuum in Inches	S.H.P.	Knots per Hour	Knots per Day	Knots per Year 150 Days	Loss in Knots per Year	Loss in Dollars per Year at $13.00 per Knot
28	2500	11.5	276	41400	0	0
27	2285	11.16	267.84	40176	1224	$15,912.
26	2120	10.88	261.12	39168	2232	29,016.
25	1980	10.62	254.88	38232	3168	41,184.

Another interesting analysis would show that if the original vacuum of 28 inches was maintained instead of 27 inches the same power might be had with one-sixth less steam per hour or in round numbers about 5,000 pounds of steam per hour. This amount of steam per hour represented in terms of fuel, providing the boiler efficiency remained the same would be approximately four tons of fuel oil per day. If the oil was worth $12.00 per ton and the ship was steaming 150 days a year this would amount to $7,200 per year.

There are two ways then in which you might have saved money. The first was to get the better vacuum, therefore full power and speed, make a greater mileage per year which is the true representation of the ship's earning value and in the typical case shown represented nearly $16,000 per year in increased earning capacity, or in the second case get the better vacuum, shut off two nozzles, save five thousand pounds of steam per hour or four tons of fuel per day and amounting in a year's time to $7,200.

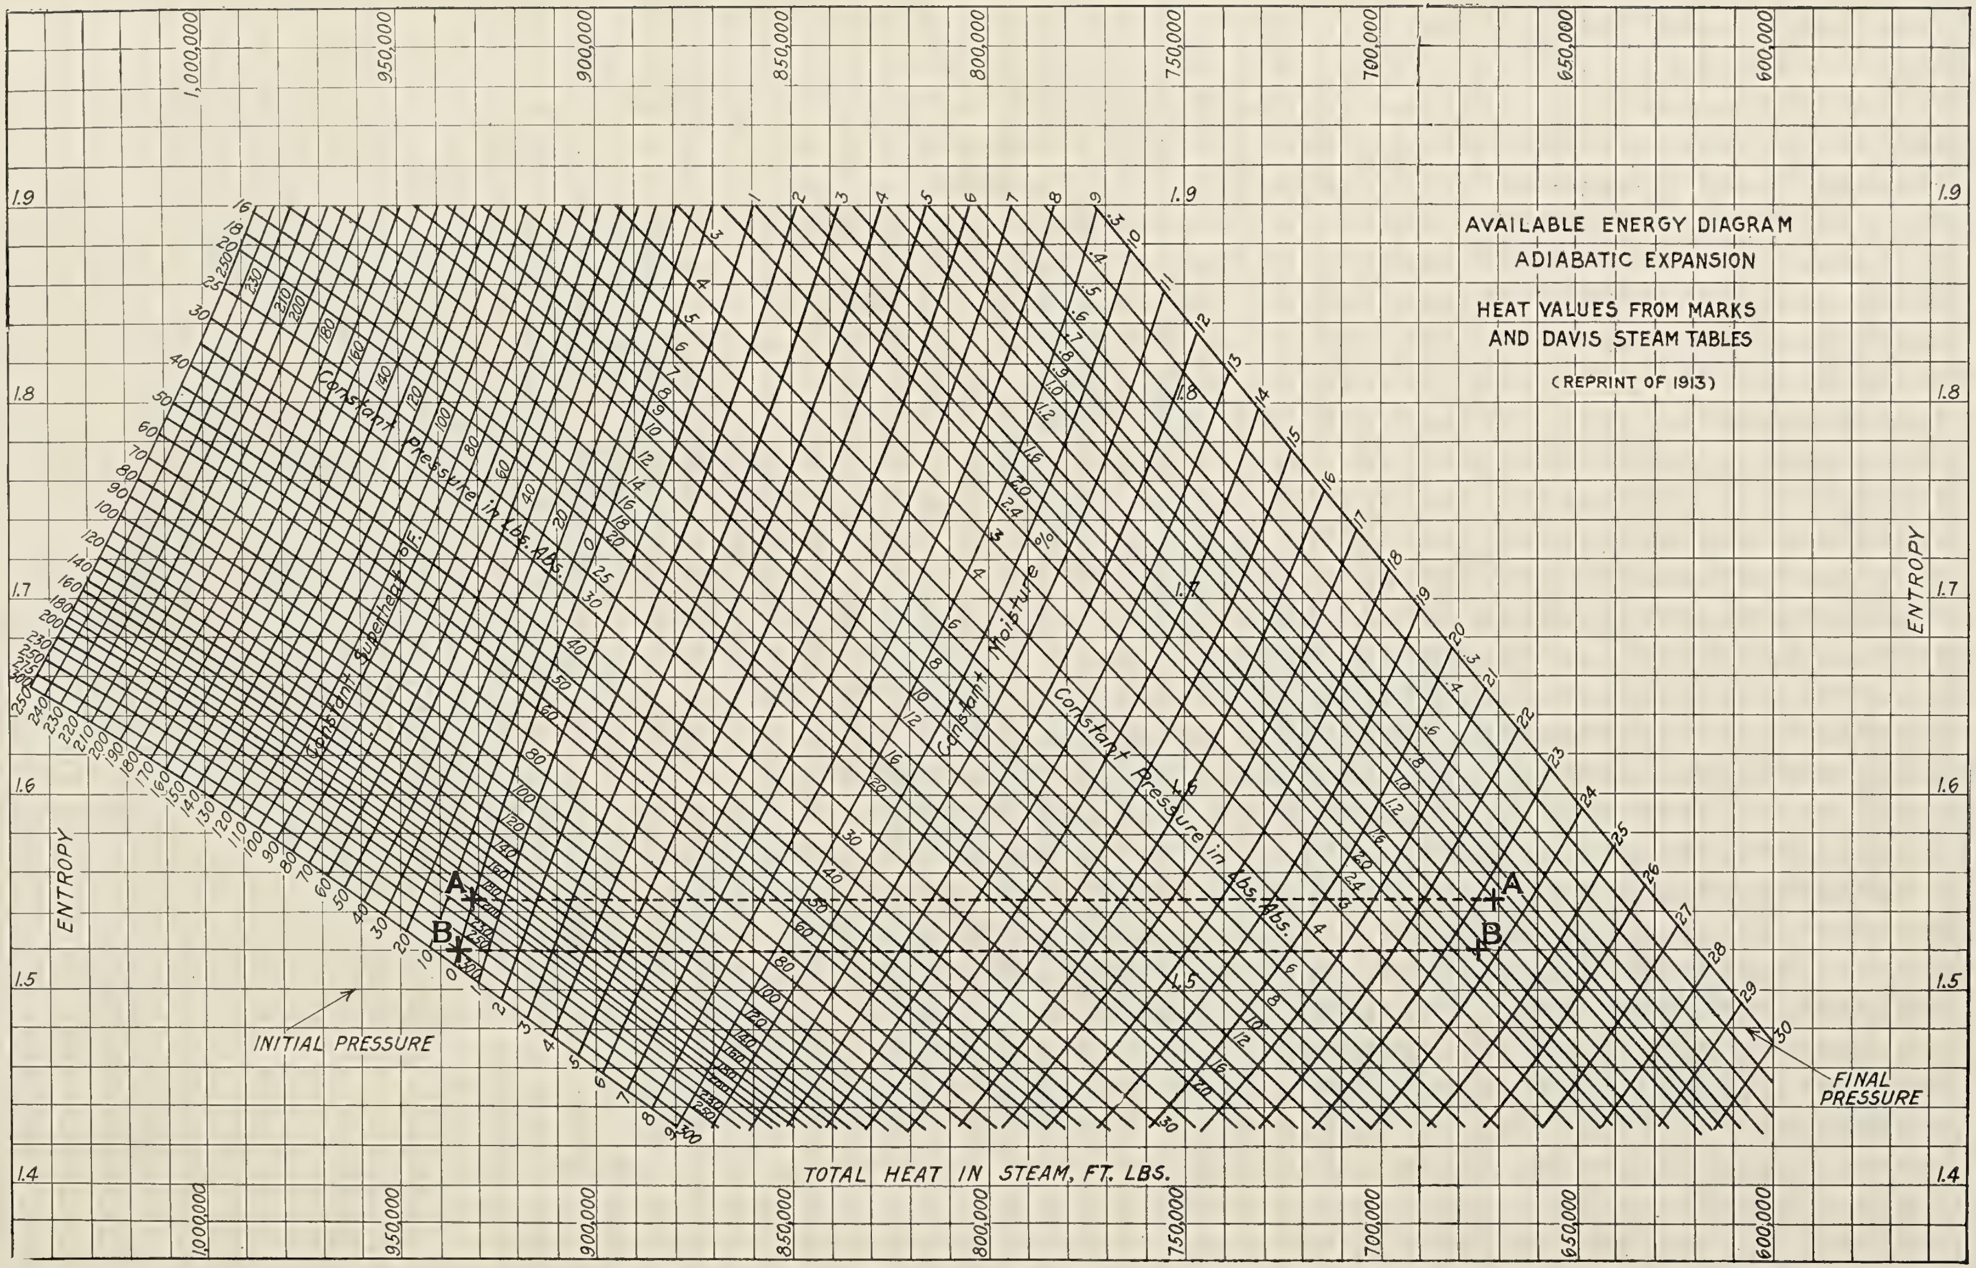
Value of Trained Engineer

You can readily see that in either case an engineer who does not fully understand the value of high vacuum in connection with turbine installations is a costly investment to any operating company. He not only wastes fuel that is worth more than his salary but also decreases the speed of the ship unnecessarily and places it in a field where it cannot possibly meet the keen competition of today, and which means either bankruptcy for the operating companies or the immediate tying up of the vessel to avoid loss. You have seen enough of the evidences of the latter movement so that it will not be necessary to go into the details regarding this feature.

When you consider the fact that if only ten men a year, who were trained at the Shipping Board schools, which were maintained at the various manufacturing plants, were successful in maintaining the proper vacuum on these ships that it would either increase the earning capacity of the same number of vessels $160,000 (an inch to the man) or result in the saving of $72,000 per year in fuel, you can gain some idea as to the value of a trained engineer.

*Abstract of paper read before a meeting of the Marine Engineers' Beneficial Association, New York, January 23, 1922.

†Marine Engine Department, General Electric Company, Schenectady, N. Y.



A—Initial Pressure, 200 Pounds Absolute; Vacuum, 28 Inches; Absolute Back Pressure, 1 Pound; Available Energy = 932,000—670,000 = 262,000 Foot Pounds
B—Initial Pressure, 275 Pounds Absolute; Vacuum, 27 Inches; Absolute Back Pressure, 1.5 Pounds; Available Energy = 935,000—675,000 = 260,000 Foot Pounds

Appendix

The mathematical calculations of steam are quite complex. As a general rule in turbine calculations the "Total Heat"—Entropy Diagram ("The Mollier Chart") is used and the work done graphically as far as possible. These charts are obtainable with Marks and Davis' "Steam Tables." In our work, however, we go a step further by using a chart in which the total heat is multiplied by the mechanical equivalent of heat (1 B.T.U. = 777.5 foot-pounds) in order that the result may be in foot-pounds and the theoretical water rate be more readily obtained.

Example: (1) Initial pressure, 200 pounds, vacuum 28 inches —(2) Initial pressure 275 pounds, vacuum 27 inches—are marked respectively "A" and "B" and worked out on the accompanying Available Energy Diagram and also by mathematical calculation.

Formula for Calculation of Available Energy

The formula for calculating the available energy of steam expressed in foot-pounds, either dry or superheated, when expanding adiabatically to any back pressure, is seldom found in handbooks or textbooks, and when such formulas are found they are rather complex and difficult to use. The formula can, however, be made very simple when expressed as the difference between the total heat input and the heat left in the liquid together with the latent heat in the mixture at the lower pressure. The formula then becomes:

Available energy in foot-pounds =

$$778\ [H_1 + C_p t_1 - (q_2 + x_2 r_2)]$$

H_1 = Total heat of saturated steam at intial pressure p_1.
C_p = Specific heat of superheated steam.
t_1 = Degrees F. superheat at pressure p_1.
q_2 = Heat of the liquid at lower pressure p_2.
x_2 = Quality of the steam at pressure p_2.
r_2 = Latent heat at pressure p_2.

All of these quantities are found in any steam table except x_2 (dryness factor) which is, however, easily calculated from the fact that the entropy is constant before and after the expansion.

Entropy of superheated steam is:

$$C_p \log_e \frac{T_1 + t_1}{T_1} + \frac{r_1}{T_1} + \phi_1$$

Entropy of moist steam is:

$$\frac{x_2 r_2}{T_2} + \phi_2$$

By making these equal and solving for x_2 there results:

$$x_2 = \frac{T_2}{r_2}\left(C_p \log_e \frac{T_1 + t_1}{T_1} + \frac{r_1}{T_1} + \phi_1 - \phi_2\right)$$

T_1 = Absolute temperature at pressure p_1.
T_2 = Absolute temperature at pressure p_2.
ϕ_1 = Entropy of water at pressure p_1.
ϕ_2 = Entropy of water at pressure p_2.

Available Energy of One Pound of Steam Expanded Adiabatically

Steam Conditions and Calculations

		"A"	"B"
1.	Initial pressure, lbs. abs.	200	275
2.	Total heat initial pressure, B. T. U., ...	1,198.1	1,202.9
3.	Entropy of steam, initial pressure	1.5456	1.5199
4.	Final pressure, lbs. abs.	1.0	1.5
5.	Total heat, final pressure, B. T. U.	1,104.4	1,110.5
6.	Heat of water, final pressure....	69.8	83.7
7.	Entropy of water, final pressure..	.1327	.1573
8.	Entropy of steam, final pressure..	1.9754	1.9417
9.	Entropy of complete evaporation = (8-7)	1.8427	1.7844
10.	Entropy of evaporation to condition at end of expansion = (3 — 7)	1.4129	1.3626
11.	Final quality = (10 + 9)	.765	.763
12.	Heat at end of expansion = 6 + [11 x (5 — 6)]	861.27	867.15
13.	Available heat (H_1 — H_2) = (2 — 12)	336.83	335.75
14.	Available energy in ft. lbs. = (H_1 — H_2) × 777.5	261,885.0	261,046.0
15.	Theoretical water rate per H. P. hour = $\frac{1,980,000}{(14)}$	7.6	7.6

16. Actual water rate per S. H. P.

$$= \frac{(15)}{\text{Turbine Efficiency}}$$

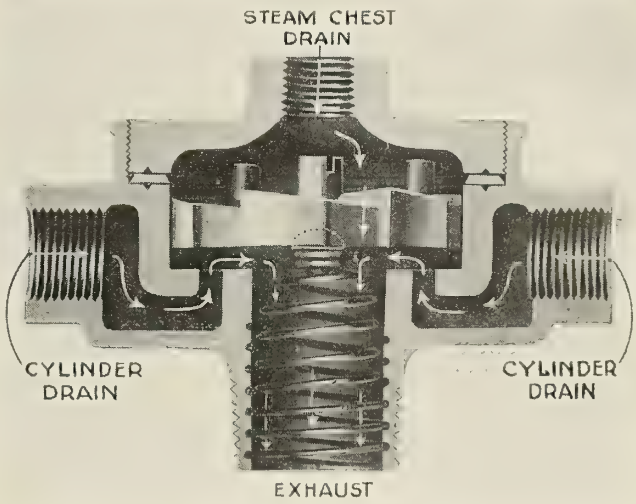
From the above calculations it is obvious that the amount of available energy that may be transformed into useful work in a turbine is practically the same in both cases (less than 1/3 of 1 percent difference and in favor of the lower initial pressure and higher vacuum).

All heat values were taken from Marks & Davis' "Steam Tables."

Automatic Drain and Relief Valve for Steam Reciprocating Equipment

For draining condensate and water from the cylinders and steam chests of reciprocating steam operated equipment the automatic relief valve being distributed by the Diel-More Sales Company, Inc., Philadelphia, Pa., has, in a wide application to equipment of this kind, tended to decrease the maintenance and repair costs by permitting the oil to function properly.

The valve is made entirely of brass and includes but one moving part—a self-grinding disk valve. The spring which supports the disk valve is adjustable, which feature permits



Sectional View of Automatic Drain and Relief Valve

considerable latitude in the pressure necessary to actuate the valve. When the engine or pump on which the valve is installed is at rest, the adjustable spring raises the disk valve thereby permitting the water to escape through by-passes to the waste pipe which eliminates the possibility of the operator neglecting to open the ordinary hand operated drain cocks after stopping the engine. Positive drainage is thus provided which prevents water remaining in the cylinder and freezing in the event of a shut down in cold weather. When the engine is operating, the disk valve is seated by the pressure carried in the steam chest (which pressure is constant).

The by-pass feature mentioned is claimed to be advantageous for direct connected engines (such as locomotives). With ordinary cylinder drain cocks exhausting hot air alternately to the atmosphere cold drafts of air are sucked in with each stroke of the piston. This air is objectionable and dangerous to hot cylinders, frequently causing warping or even cracking. Since the new valve does away with all ordinary drain cocks the liability of warping or cracking from this cause is also eliminated.

The valves are supplied with steam chest connections from ¼ to 1 inch diameter with either two or four parts and exhaust pipes from ½ to 1½ inches in diameter.

The Most Interesting Job in the Yard

Previous issues of MARINE ENGINEERING AND SHIPPING AGE *have contained letters from a machinist in the engineering department, an engineer in the engineering office, an engine erector and a draftsman in the hull department—all giving substantial reasons why their particular jobs are the most interesting in the yard. This month these claims are disputed by a ship joiner. How about YOUR job? Tell us about it.*

As a ship joiner, who served his apprenticeship in the shop, on the ship and in the drawing room, I would like to tell about the most interesting job in the yard—ship joinery. What could be more interesting than taking the rough lumber and fashioning it into beautiful and comfortable furniture for dining saloons, smoking rooms, staterooms, etc., for the passengers and at the same time turning the cold ship into a *home* for the men who "go down to the sea in ships?" There is so much to joiner work that I will briefly outline but a few things.

Starting first in the joiner shop drawing room (it may seem odd but joiners are proud of their draftsmen and consider them always as joiners), let us assume that the yard has a large passenger ship to build. The draftsman receives a plan of the arrangement of quarters, the specifications and all necessary reference plans, such as plans of steel deck houses, casings, bulkheads, shell plating, framing, decks, transverses, stanchions, heating and sanitary systems, fire mains, ventilation, sounding pipes and electrical plans.

In the Joiner Shop Drafting Room

As an example, let us take a public room, say the smoking room, and draw the deck plan of the ship to scale, say three-quarters of an inch to the foot. After we have laid down the center line and outlined the steel bulkheads and casings around this room, we spot the stiffeners and figure on fastening our furring. Then we can indicate the tongued and grooved lining and decide on the size of the room, face to face of the lining.

We next work up the different sections through the room to find interferences, such as brackets, girders, pipes, etc. Then the design of the room is laid down, always bearing in mind to work in with all piping and ventilator systems, and the electrical wiring, etc. We work the cornice over the steel brackets, unless the brackets are too large and spoil the design. In that case we get the hull men to cut the brackets out on a curve, which does not impair the strength, and also makes a better job of the joiner work.

The girders we case in, bearing in mind that all steel work must be covered so that a person on coming into the finished room sees everything in line and symmetrical. The windows, likewise, will have to be located to suit the joiner work. We always work as near to the steel plans as we can; then fight with the hull drawing room to have a stiffener shifted, if necessary (on the plan, never on the ship).

Now we are started and each section of panel work, the columns, cornice, beams and girder casings, moldings, tongue and groove, furring, window and door trim, sash, screen, blinds, doors and furniture are detailed, each on a separate sketch and sent through the shop to be manufactured.

These sketches first go to the shop leader, who lists all material, and then the lists go to the cut-out sawyer, who cuts out all material in the rough, then to the jointer, planer, sticker or lathe, according to the operation to be performed, then to the layer out, who lays out the lumber for mortising, tenoning, ploughing, rabbeting, fluting or carving, or to be glued up, then to the various machines, then to the sander or scraper, then to a bench hand to be assembled, hand sanded and scraped, then to the hardwood finisher or painter for the finishing. Finally, the hardware is installed in place, if called for.

Now the finished material is ready for the ship. We go out on the ship with steel tape, chalk line and camber board—checking up the steel so as to get the joiner work installed *exactly*. We find that the room is about 1½ inches smaller in length than the steel plans called for—the deck has sagged in places. Now we have to use our heads for the finished room must be correct, so we take up (steal, the joiners say) a little here and a little there until the panel work, cornice, etc., line up so fair that even the old time joiner inspector, who squints one eye and swears he can see anything fifty feet away that is out of line one-sixteenth of an inch, passes the room as O. K.

The Work on the Ship

The room is now shaping up and beginning to look good. You have a force of say twenty joiners in this room. You know what every man is capable of doing and what particular work he can best perform. The old joiners are expert in all the work, and so are some of the young ones, who served their apprenticeship before the war. You put Bill at fairing up the cornice, Joe at hanging doors and Tom at fitting sash and screens. You notice with pride how neat and efficient they are at work, how Bill never hits the moldings without using a block, how careful Joe is that he does not split out the wood when he cuts out for the lock and hinges and how particular he is that the slots in the screw heads line up so they will not annoy the eye of a good joiner when he sees them. And there is Tom just taking enough off the sash or blinds so they will not rattle and annoy the passengers and at the same time give them enough clearance so they will work. Every piece of wood seems to have life. The men take pride in their work. They would sooner lose a finger than have it said their work was not right. It is the most interesting job!

The Critics Arrive

It is noon. The men sit down and eat their lunch right on the job. Between bites they glance around the room to see if their work looks perfect from other points of view. The crowd starts in to see the joiner work—a couple of draftsmen or clerks from the main office, here a riveter, there a bolter or driller, a few machinists and plumbers, a ship carpenter and electrician. It is interesting how it draws all of them.

You slip away to make up your time book and meet the other foremen and you just have to say what a good joiner Low is or Charlie is.

(And Mr. Editor, if this article is printed, it will be the first time to my knowledge that any article about "Ship Joinery" was printed, as ship joiners, for some reason, will never write anything about their trade. It is a secret art. During the war, thousands of men worked at ship joinery and now they think they are joiners—but it takes the "old timers" to build an elliptical front paneled pilot or deck house, and to develop the sills and plates, moldings, paneling, sash, etc., where they have camber, sheer, rake and a radius all running together, or to build the fancy wooden skylights, etc., they used to build.) I trust that the old joiners will forgive me for writing this—but let us hope that this will wake " 'em" up, so they can mark time with the iron trades and finally pull ahead. JAMES T. STRAHAN.

West Collingswood, N. J.

Ferryboats Can Be Operated On More Economic Basis

Outline of Method and Sketch of Arrangement of Machinery for Eliminating Waste on Double Ended Boats

By H. Schreck

THE uneconomical propulsion of double ended boats led the writer to make a careful study of this condition, which finally resulted in a device which will eliminate the waste of power encountered on the present day arrangement of these boats. This problem has for years been a subject of calculations and tests in order to establish the amount of said waste of power.

This type of boat is in general laid out with one triple expansion engine or two compound engines in tandem arrangement in the middle body of the boat. The shaft runs to each end of the boat and carries one propeller at each end; one of these propellers pushing the vessel ahead and the other pulling the boat. When the boat is reversed the engine is reversed and in turn also the respective working of these two propellers. Some boats are driven by two through shafts in which case the above described plant is simply duplicated.

It is well known that the low propulsive efficiency of these boats is due to the dragging of the forward screw and to the hydrostatic pressure of the water column, which the forward screw builds up on the bow and on a great part of the forward length of the hull. It is readily seen that in this manner a large part of the energy which is put into the forward screw is very largely lost and the output of the engine must be increased by the amount of said increased resistance of the boat in comparison to an ordinary ship with one screw aft.

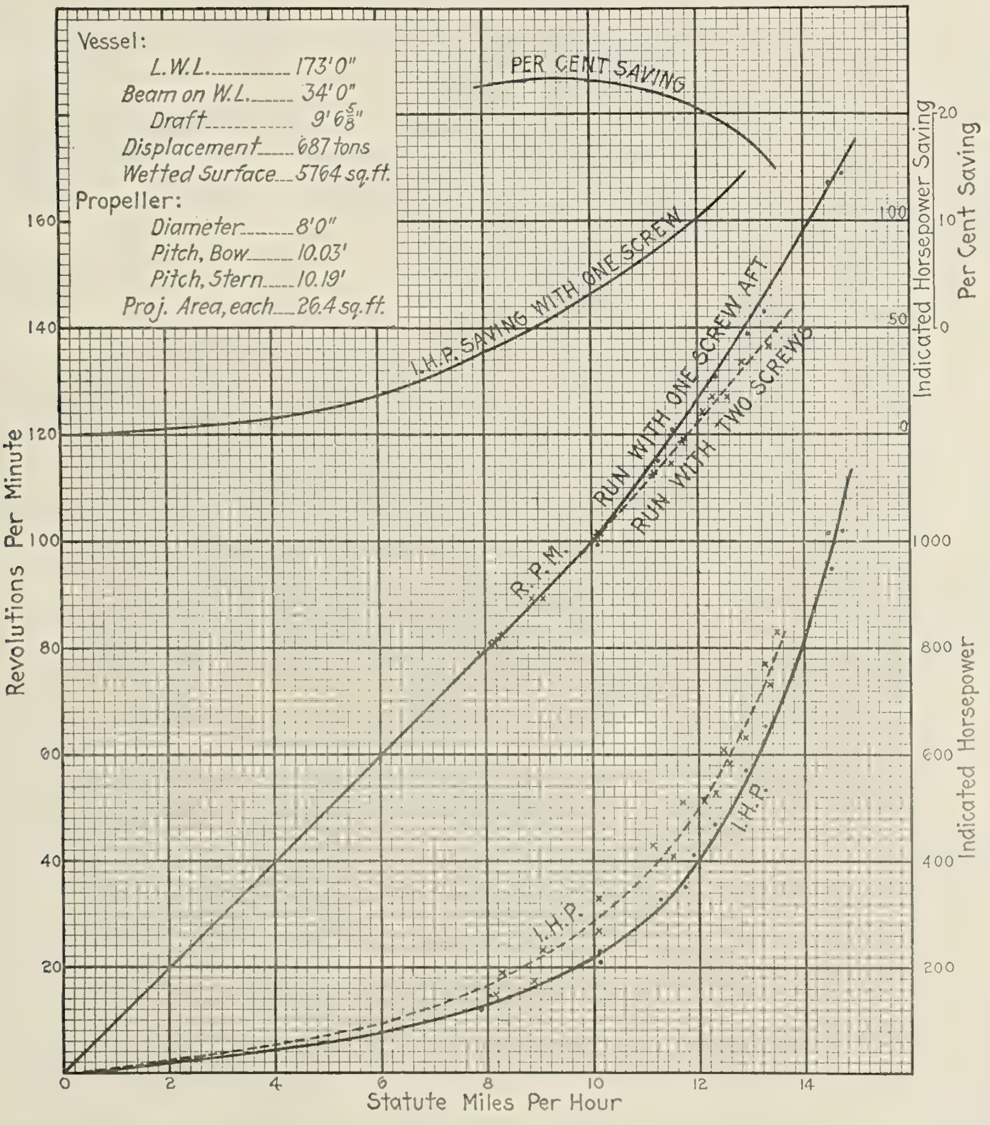
Tests

The experiments and calculations, to which reference was made in the introductory paragraph, have been carried on in an elaborate and painstaking manner on many existing ferryboats by prominent engineers for the past twenty years, and the studies by such men as F. L. DuBosque, Col. E. A. Stevens, Commander S. M. Robinson and others will remain of permanent value to the marine engineer.

In the accompanying chart the results of the progressive trials of the *Edgewater* were plotted from the test sheets, which were made and published by Col. Stevens in 1902 in the Transactions of the Society of Naval Architects and Marine Engineers. These tests were run in three ways: first, with both screws in place, one forward and one aft; second, the forward screw removed, the boat being pushed only by the aft screw; and third, the aft screw removed, the boat being pulled by the forward screw. The latter results are not plotted in the chart on account of the extreme losses and because they are of no commercial value.

Although this chart hardly needs any explanation, it may be shown by one example how to read the chart. Assuming the boat is to run twelve miles an hour, we follow the twelve-mile line and find that at this speed the vessel requires, when driven by two screws, 502 indicated horsepower and driven by one screw 400 indicated horsepower, which would mean for the latter case a saving of 20.3 percent.

These losses or waste of energy will, of course, vary on various ships with the shape and speed of the vessel and location of the screws in relation to the hull and the characteristics of the propeller. A few other results may be quoted as follows:



Results of Progressive Trials of Ferryboat Edgewater

Line — and points designate I. H. P. when boat is driven by screw astern only.
Line - - - and crosses designate I. H. P. when boat is driven by screw ahead and astern.

On the *Cincinnati,* of the Pennsylvania Railroad, the loss of power due to the forward screw at eleven miles speed was measured to be 20 percent. The results of another ferryboat were published in the December, 1920, issue of this paper. At a speed of 12.75 knots an increase was required in effective horsepower, due to the forward screw, of 37 percent and an increase of total indicated horsepower of 23 percent. In the May, 1921, issue of *Pacific Marine Review,* the tests of a large ferryboat on the Pacific Coast were published. This boat required at a speed of 14.77 knots, with both wheels, 3,010 indicated horsepower, and with the forward wheel taken off 1,740 indicated horsepower, which represents in the latter case a saving of 42 percent.

Suggestions have been made and followed out to overcome this waste by using a propeller without backing power. Propellers which embody this demand, as much as possible, are running on some ferryboats. It is claimed, however, that the maneuvering of the boat is very unsatisfactory.

Trend of Eliminating this Waste

There are three characteristic methods of propulsion of double ended ferryboats and in illustration some of the figures of a previously mentioned publication by Commander Robinson will be utilized.

If we consider his boat of 191 feet length, 44 feet beam, and running at a speed of 10 knots, the total towing power with two screws of 680 effective horsepower and with only the after screw 496 effective horsepower the following three arrangements may be investigated for this boat:

1. The present day arrangement, that is, one main engine.
2. Two motors, each transmitting about half of the power. However, each one can be turned at its respective most favorable speed.
3. Two motors, one at a time transmitting the full power for pushing the boat, while the other motor turns the screw over at about the speed of the boat, but without doing any work. This condition is reversed for running the boat in the other direction.

	I		II		III	
Screw	Aft	For'd	Aft	For'd	Aft	For'd
R.P.M.	116.9		114.7	119.8	131	117
I.H.P.	656	389	564	460	838	38
I.H.P. Total	1045		1024		876	
Gain over I					16%	
Gain over II					14.5%	

* Clutch

It can be readily seen that the gain of case 2 over 1 is very little, which is evident from the fact that in case 2 the forward propeller still throws the column of water against the bow of the vessel. A marked gain in propulsive efficiency is, however, made in case 3, in which the forward propeller does no work, but is merely turned over. The turning will require only about 4 percent of the power, as it is only necessary to overcome the frictional resistance of the propeller blades and of the shafting.

This arrangement is, as to propulsive economy, practically equal to an ordinary ship with the screw aft. The first cost is, of course, very much higher since it requires two full power motors and in addition a generating set, and the overall efficiency is lowered by 15 to 18 percent of the power due to the electric transmission by generator and motor.

A part of this electric loss is offset by the fact that the generator set can be a high speed turbine, which works more efficiently than the reciprocating steam engine. With this arrangement Diesel engine generator sets would produce far greater substantial saving.

Suggestion of the Writer

In order to accomplish the maximum propulsive efficiency, the writer suggests an arrangement which will combine the advantages of cases 1 and 3 at the smallest cost of installation and the possibility of building it in on existing boats (a patent on this combination is pending).

The suggestion is to interpose a clutch at each end of the main propelling unit between same and the two propeller shafts. This clutch, which may be a magnetic or hydraulic one, will allow varying the power transmitted and the speed of the after shaft in relation to the forward shaft; that is, when the boat is going ahead almost the full power of the main engine will be transmitted to the aft screw, while the forward screw will be merely turned over at about the speed of the boat, but without doing any propulsive work. Clutches that fulfill the above requirements have been investigated and are being built.

Expected Savings

An example may be cited which will allow the reader to form a conception of the savings which can be effected by providing a ferryboat with the suggested improvement. Taking, for instance, a ferryboat of 1,400 indicated horsepower, the following results may be obtained:

Thirty percent saving in propelling power = 420 indicated horsepower. Assuming the boat to run 10 hours a day for 300 days of the year. Take the cost of coal at $9 per ton and the coal consumption, including auxiliaries, at 2 pounds per indicated horsepower.

$$\frac{420 \times 2 \times 10 \times 300 \times \$9}{2,240} = \$10,120$$

Reduced cost in handling of coal and reduced boiler repair bill, estimated	3,500
Saving per year..............	$13,620

It will be noticed, that the estimates are made very conservatively. The saving of 30 percent is taken as an average of actual tests. Also 10 hours' operation is very little, since most ferries run for 14 to 16 hours and some of them for 24 hours. Very conservative also is the figure of 2 pounds of coal per indicated horsepower for compound engines, but the writer has tried to make all his statements as carefully as possible.

National Foreign Trade Council Urges Adoption of Hague Rules

American shipowners and operators are urged by the National Foreign Trade Council to issue, as soon as possible, bills of lading drawn in conformity with the Hague Rules, 1921. The following statement represents the views of the executive committee of the council, of which Mr. James A. Farrell, president of the United States Steel Corporation, is chairman.

"The committee believes that these rules embody as favorable a readjustment of the distribution of liability between shipper and carrier, as can at present be secured. While fully cognizant that these rules do not satisfy many of the demands of shippers, the committee is of the belief that their adoption will constitute a substantial step in the right direction and will, in fact, confer very real benefit on the foreign trade of the United States."

Deck Coverings

By Horace Holden Thayer*

Continuation of a series of articles containing information regarding shipbuilding materials and their uses that is not readily obtainable from shipbuilding handbooks and other generally available sources. The articles are not intended to be a complete exposition of the subject but will be found to contain items of value to the various classes of workers in this field who have to deal with these materials from the materials point of view.

THIS article is concerned with special forms of deck covering that are frequently met with. It is not concerned with the usual run of wood decks, canvas, paint, or those bituminous coatings whose principal purpose is to act as a preventive of corrosion. As a number of the deck coverings are put forth under trade names which do not clearly define their character, such names of American products as the writer has come in contact with will be presented in order that the reader may be advised as to what class of product they belong. No attempt will be made to compare proprietary coverings of the same nature with one another.

Ship specifications generally state the types of deck covering that are to be used in various locations, but there are usually a variety of points to be considered before the specific covering is finally determined upon. In making these determinations classification society requirements should not be overlooked.

The principal points to be considered in the selection of deck coverings are below listed, and the type determined upon for any location should be the one which is best in those features that are of most importance for that particular service and for the main governing circumstances. The preparation of a typical schedule of general application is impossible.

Weight
General durability
Appearance
Wearing qualities
Resiliency
Waterproof and sanitary properties
Non-slippery
Quietness
Warmth
Cleanliness
Fireproof
Probability of failure
Cost

In laying deck covering it can be stated as a general requirement that the deck should be absolutely dry and clean, and free from scale, oil or other foreign matter.

Alundum Tile

See "Tile" Class (b). This tile is particularly slip proof.

Asbestolith

See "Composition."

Beaver Tile

See "Cork Composition Tiling."

Bitucrete

See "Bitumen Deck Coverings" Class (c).

Bitumen Deck Coverings

These are heavy coverings for hard usage such as the truck ways of ferryboats or on troopships. The material is also of value for the bottom of chain lockers. They are of four general classes and various special types all of which have asphalt as the binder. Asphalt is a black bituminous hydrocarbon, semi-fluid to hard in consistency, which is the heavy residuum from some petroleums or occurs naturally. As made up for use it is usually called asphalt cement. The four usual classes of covering are:

(a) What is commonly known as asphalt, which is a mixture of native or prepared asphalt cement and stone dust.
(b) The same as (a) but with larger stone, slag, coke or other aggregate in it.
(c) A covering made by coating the deck with the pure asphalt cement and then laying down a layer of hot stone which draws the asphalt up through it.
(d) A covering made by the use of cork bricks, bituminous bricks or other material of that nature laid in the standard bituminous solution and enamel coating and with the enamel poured between the cracks and over the top, and the top sanded.

In all four cases the deck should be first coated with a bituminous paint as a binder, and with class (c) a 2-inch mesh wire fabric welded to the deck is desirable.

Class (a) is laid hot, sanded on top and rolled or tamped, then the excess of sand is brushed off, Portland cement is sprinkled over the surface, and it is again rolled or tamped. The composition is usually about—

Asphalt cement	10	percent
Stone passing 200 mesh	13	percent
Stone passing 80 mesh	23	percent
Stone passing 40 mesh	27½	percent
Stone passing 10 mesh	26½	percent
	100	percent

It weighs about 102.5 pounds per square yard per inch of thickness.

It can also be laid upon a bottom course containing still less asphalt and with stone up to one mesh in size, or can be laid on a backing of other material.

Class (b) material is also laid hot but some of the mixtures do not require rolling. It can be made lighter than class (a) by using coke or other light aggregate. The stone in class (c) is usually small, up to ⅛ inch and the coating is rolled.

Bitumen deck coverings demand an asphalt cement of high melting point, ductility and cementing power and low penetration, the latter being a measure of the distance a weighted needle will sink into it during a specified time at a specified temperature. It also demands skilful mixing and laying. If not of proper quality and well laid, it is subject to cracking and pulling away from bounding angles, etc., to disintegration, scaling and very easy marking and displacement. It is always subject to cracking when not in constant use because there is a gradual passing off of volatile matter which results in the materials soon becoming dead unless the surface is kept alive by the traffic over it.

An asphalt deck covering was developed by the Concrete Ship Section of the Emergency Fleet Corporation which called for the use of an asphalt cement having a melting point from 104 to 140 degrees Fahrenheit, a penetration of 80 to 90 at 77 degrees Fahrenheit, 100 grams, 5 seconds, and which did not specify the ductility. The covering was made from this asphalt and stone particles 100 percent of

*Member of the firm of Rossell & Thayer, naval architects and marine engineers, Philadelphia, Pa.

which would pass a $\frac{1}{4}$ inch sieve and not over 5 percent of which would pass a 100 mesh sieve. It was found to be too soft and the specifications were revised to call for an asphalt having a melting point from 135 to 150 degrees Fahrenheit, a penetration of 40 to 60 and a ductility of not less than 20 centimeters. The sand was as before and a mineral filler was called for of any fine material such as Portland cement, limestone dust or silica, 85 percent of which would pass a 100 mesh screen. The requirements with regard to mixing and application were:

Formula for mixing—Asphalt cement—10 to 15 percent
Mineral filler 20 percent
Sand or other aggregate 70 to 65 percent

The sand or the mixture of the sand and mineral filler and the asphalt cement shall be heated separately to about 300 degrees Fahrenheit and when the aggregate is dry and the asphalt cement completely fluid, they shall be thoroughly mixed. If limestone dust is used, it shall be mixed cold with the hot sand just before incorporating it with the asphalt cement.

The hot mixture prepared as above shall be spread on the deck previously coated with a priming coat which has become tacky and shall be smoothed out with suitable hot iron and rolled. Before rolling, the surface should be sprinkled with Portland cement or limestone dust.

The properties of natural asphalts and typical asphalts from Mexican and Californian crude oils are of interest in this connection. Pennsylvania crude is a paraffin base oil and cannot be made to produce asphalt.

	Natural		Oil	
	Trinidad	Bermudez	Mexican	Californian
Bitumen, percent	56.0	94.	99.5	99.5
Mineral matter, percent	36.8	2.	.3	.3
Melting point, degrees F.	190	180	140	140
Penetration	.5	2.5	55	40
Ductility			45 cm.	2 cm.

The natural asphalts are considered to be the best. They can be modified to have any desired penetration, with corresponding change in the other properties. In some cases the melting point of oil asphalts is raised and the penetration lowered by blowing air through them during manufacture but this is at the expense of ductility and cementing power, and such asphalts are of no value for flooring purposes.

Breylite

See "Bitumen Deck Coverings." Class (b). This coating with a stone or slag filler weighs about 27 pounds per square foot, $2\frac{1}{2}$ inches thick.

Brick

The use of brick as deck covering is confined principally to the galley, oven rooms, etc., and red pressed bricks are most favored. They are laid on Portland cement thick enough to take care of all irregularities and also to have sufficient body in itself to keep from breaking up.

Brick Tile

Brick tile are used where bricks are used, and also in pantries, bar rooms and other locations where frequent washing is desirable and where bricks are not quite good enough.

Their wearing qualities are shown in the comparative table in the section on "Composition."

They should be laid in Portland cement, a 1 to 2 mix, about $1\frac{1}{2}$ inches thick, and grouted with Portland cement grout.

Cement Deck Covering

This is a mixture of Portland cement and sand and as a complete covering is of principal value in crews' washrooms and toilets, laundries, sculleries, storerooms and similar service.

The surface under wear produces a fine powder. Surface waterproofing compounds can be used to harden the surface and reduce this trouble, but are not required for the usual shipboard service of this covering.

As will be seen from the wear resistance table in the section on "Composition" a mixture of one part cement and one part sand is most desirable. When used in connection with a surface covering of some material a mixture of one part cement to two parts of sand will usually answer. The Navy Department requires a 1 to 1 mix under tiling.

This deck covering weighs about $12\frac{2}{3}$ pounds per square foot per inch of thickness.

Composition

A deck covering which is essentially a magnesium oxychloride cement is designated as a composition deck covering. It is one of the best and, therefore, extensively used.

The most valuable features of a composition deck covering are that it is durable, sanitary and vermin proof, free from splintering and from the sanding out that is frequent with Portland cement, allows of good color effects and beauty of finish, and is non-slippery. This material is also of relatively light weight and is watertight when in good condition. It is comparatively noiseless to the tread and quite efficient as a thermal insulator.

The chief disadvantage of a composition deck covering as developed to date is that it does not retain its strength and soundness when subjected to continued wetting, that it cracks when subjected to the excessive heat sometimes found above boiler rooms and other heated spaces, that, if there is any excess of magnesium chloride in it and water penetration between it and the steel deck, rapid corrosion of the steel will result, and that it does not bond firmly to smooth steel plates. For these reasons one of the classification societies during the height of the wartime shipbuilding activities sent out the following excerpt from their published rules to deck covering manufacturers:

"Deck Composition may be laid on steel decks which are not exposed to weather, excessive moisture or heat, provided the material is not destructive to steel or is effectively insulated from the steel by a non-corrosive protective covering, which is proof against attack by chlorides. Samples taken from the composition by the surveyors, while it is being laid, are to be subject to independent analysis at the cost of the manufacturers. The steel plating is to be thoroughly cleaned with alkaline solution before composition is laid. Large areas of deck are to be divided by cabin sills, angles, etc., or holdfasts are to be fitted not more than 3 feet apart."

Roughing up the steel deck or curling up chips of it, with air tools, is allowed by the classification societies in lieu of the above mentioned holdfasts, but the latter have much to commend them. The non-corrosive protective covering referred to, which is generally recommended by classification societies, consists preferably of two coats of a bituminous solution that will permanently adhere to the steel deck without cracking. With some makes of composition this covering is definitely required. In locations where the composition would be exposed to excessive heat, if laid in the usual way, it can be used with safety by the interposition of a layer of cork slabs between it and the steel, the steel first being coated with the above mentioned bituminous covering. It is held down by properly placed holdfasts extending above the cork.

On wood decks the practice is to lay down heavy insulating paper over which expanded metal or heavy galvanized poultry wire is securely nailed. The composition is then applied.

Reliability of Manufacturer Important

The writer is of the opinion that the best specifications for composition deck covering which can be devised will not safeguard the shipbuilder and owner like *the selection of a manufacturer whose product has been proved to be good*

and who has a reputation to maintain. A selection of the material on a competitive price basis alone, under such specifications as are usually met with, is suicidal. This may be readily seen by those who are sufficiently interested to follow along with the discussion of this material, which includes many of the findings and the conclusions derived therefrom of the Dow Chemical Company of Midland, Mich., which has done a vast amount of very valuable research work on this product for use both as stucco and as floor covering.

True magnesium oxychloride cement without the special ingredients required for floors consists of:

Aggregate, which is usually "silex" or powdered silica, crushed from quartz and consisting almost entirely of sharp and irregularly shaped particles.
Sand, relatively fine.
Calcined magnesite, powdered.
Magnesium chloride solution.

The aggregate, sand and magnesite are first mixed together in the proper proportions and then sufficient magnesium chloride is added to produce a material of the right consistency. This combines with the magnesite to form magnesium oxychloride which then acts in the same manner as Portland cement acts in Portland cement concrete. Magnesium chloride may be dissolved in water to form a solution of any strength from zero to 36 degrees Baumé, at which point the solution is practically saturated at 70 degrees Fahrenheit. At this temperature one gallon of 22 degree solution will contain approximately 4½ pounds, and one liter will contain approximately 530 grams of solid fused chloride. It is not safe, however, to depend upon any weight-volume ratio when making up a solution; it should be tested with a hydrometer that is accurate and easily read. The Dow Chemical Company has adopted a method of determining consistency by use of a series of flat ended rods of equal weight but of widely varying diameter which are applied to the surface of the deck covering immediately after mixing. Standard consistency is set by them at the point where a No. 20 rod (250-gram, 1¼-inch diameter) just fails to enter the product. This closely duplicates the consistency of the best deck covering practice.

The silex is what is known as a 120 mesh silex (95 percent to 100 percent passing a 120-mesh screen), and one sample tested by the Dow Company and considered by it to come very close to meeting the theoretical and practical requirements of the average sand to which it is to be added as a void filler had 54 percent passing a 200-mesh screen, another 41 percent passing a 120-mesh, and the remaining 5 percent passing an 80-mesh. If the silex or other aggregate is too fine difficulties will be encountered as will be seen later.

According to the Dow Company the ideal sand is one of which one-third will pass an 80-mesh screen but be retained on a 120-mesh, another third will pass a 40-mesh, and the balance will pass a 20-mesh; or one of which one-fourth will pass an 80-mesh screen and be retained on a 120-mesh, another fourth pass a 40-mesh, another fourth pass a 20-mesh, and the balance pass a 10-mesh. A commercial sand 90 percent of which passes a 20-mesh screen may be expected to be of about the proper fineness.

Composition of Magnesites

The composition of commercial magnesites varies within wide limits. The Dow Company gives the following as the average of a large number of commercial magnesites tested by it in 1919 and states also that it believes this to represent a satisfactory grade as far as chemical composition is concerned. To total up 100 percent the quantities will have to be all slightly reduced.

Ignition loss	5.0 percent
Silica	6.0 percent
Iron and aluminum oxides	1.0 percent
Calcium oxide	3.5 percent
Carbon dioxide	2.5 percent
Magnesium oxide	84.5 percent

It is necessary that the magnesite be properly calcined and not under burned or over burned.

The average fineness of commercial magnesite is about as follows:

Passing 100 mesh	95 percent
Passing 150 mesh	86 percent
Passing 200 mesh	76 percent
Passing 275 mesh	42 percent

Chemical analysis is an entirely satisfactory guide to the quality of magnesium chloride and definite specifications for it can be written on the basis of chemical analysis alone. The Dow Company advertises its magnesium chloride as averaging less than one percent of salt and of calcium chloride and containing only a trace of sulphate. The 22-degree solution has been taken by the company as the standard for use in oxychloride cements, as it has found that the mechanical strength, water resistance, abrasion resistance and all related factors are dangerously affected by the use of weaker solutions, that most good magnesites are thrown into the doubtful class and medium or poor magnesites are worthless when used with 18-degree solutions, and that trowelling troubles should be eliminated by the use of a slower setting magnesite instead of uselessly trying to patch up bad properties with the use of lower solution strengths, reserving the rapid setting magnesites for use in cool weather. They have found that solutions of 24 or 26 degrees Baumé may be recommended for use with magnesites which do not have marked expansive characteristics and which are velvety instead of sandy in texture and that while sandy textured magnesites produce products which are prone to sweating and efflorescence when made up with 26-degree or stronger solutions, the use of 22-degree or 18-degree solution is not a secure protection from these undesirable properties in their case.

Other Ingredients

With most of the ingredients outside of the magnesite and the magnesium chloride the physical properties are of much greater importance than the chemical composition.

While a true magnesium oxychloride cement of the mixture before given is very good for stucco it will not answer for deck covering on account of the demand for resilient treading, hardness, a fine finished appearance, color, etc.

Nearly all deck covering compositions contain 8 to 10 percent of color pigment, about the same amount of powdered talc, or soapstone, the latter being an aid to trowelling, and a like amount of fibrous binder filler. The amount of silex added depends upon the degree of hardness and wearing resistance desired, the larger amounts giving the harder floors. A floor of average hardness would contain about 25 percent of silex, which gives a total of about 55 percent of fine aggregate, silex, talc fiber and pigment. The calcined magnesite is usually at least 45 percent, which is much in excess of the amount necessary to fill the voids in the fine aggregate but desirable for fine finished appearance and resilient treading. The amount of fiber present is small in weight but relatively large in bulk. It is mineral or ligneous. The mineral fiber, asbestos, may be obtained in various lengths or grades, each of which finds preference by one or another of the deck covering manufacturers. The wood fibers are used either as sawdust or as pulverized wood flour of varying degrees of fineness.

The principal requirements of a composition deck covering are:

1. Strength
2. Good wearing qualities
3. Freedom from excessive expansion and contraction
4. Watertightness
5. A setting time that will allow of proper handling
6. Permanency and uniformity of color
7. Freedom from excessive sweating and efflorescence

8. Good surfacing qualities
9. Sufficient thickness of coating

Most of these requirements demand properly calcined magnesite of suitable analysis, pure magnesium chloride and good materials throughout, uniform mixing and skilful laying; but there are a number of factors which particularly affect the different properties, that illustrate what a complex problem the manufacturer of composition deck coverings has on his hands, and which we will now consider under the respective headings.

Strength

Good strength is an indication of good magnesite quality. The tensile strength of deck covering composition should be at least 500 pounds per square inch when seven days old. The compressive strength will be about four times the tensile strength. The modulus of elasticity of the average deck coverings on the market is in the neighborhood of 1,000,000, and this allows of a contraction of about .05 percent before reaching a stress of 500 pounds per square inch.

Tensile, compressive and cross bending strength tests are all important. The compressive test is more reliable than the tensile with high strength materials on account of the difficulty in securing uniform stress when testing briquettes. The cross bending test is closer to operating conditions than the straight tension and compression tests, and allows of the determining of the elastic properties of the material in comparatively simple fashion. On account of trowelling, the structure of the surface is different from that of the material beneath it; and this has led to the development by the Dow Company of a special type of test bars, approximating the structure of the material as actually used, which are tested by this method.

Proper grading, which is principally a matter of void filling, is a strength factor. There should be no large voids as the magnesium oxychloride binder, like glue, is of maximum value only when in a thin film. The sand used should be clean and pure, and free from organic matter and mud.

As previously stated the magnesium chloride solution should be 22 degrees Baumé or higher. A solution of any strength between 14 degrees and zero does not produce a true cement, a 16-degree solution is but little better, and an 18-degree solution gives only 50 percent of the strength that the deck covering can attain with use of a 22-degree solution. There is a steady but less rapid increase in strength of the covering with increase in strength of the solution above 22 degrees. Notwithstanding this fact some contractors allow the use of weak solutions under the impression that a degree or two makes no difference, leaving the matter in the hands of ignorant or incompetent workmen equipped with inaccurate hydrometers or those that are difficult to read. There is also a temptation to stretch out an insufficient supply of solution by adding water to it. Specifications and working directions should call for the use of at least 22-degree solution. By using stronger solutions less magnesite will be required for any given strength of the resultant product; and the actual volume of solution needed to produce a given stiffness of mix decreases steadily with increase of chloride solution strength.

Excessive amounts of chloride solution reduce the strength, although wet mixes show somewhat higher strength after being wet and dried again than those of normal consistency. This last is fortunate as the tendency, to make the work easier, is to apply the material in a condition wetter than it should be.

The use of an aggregate of impalpable fineness such as Kieselguhr results in inferior strength.

Wetting decreases the strength and a mix which gives high strength when tested dry may lose all of its strength on being wet, while another originally weaker will stand up better. Some workers with this material feel that the use of 18-degree chloride results in a superior product as regards water resistance to that when 22-degree chloride is used but tests made by the Dow Chemical Company show the contrary to be the case. These tests, however, have led them to the conclusion that the water resistance, or the strength after having been subjected to wetting, of any particular oxychloride cement will be found to be a function of the amount of chloride used.

Furthermore compositions produced by some magnesites, which stand at the top of the list as regards strength when dry, are much inferior when wet to those produced by other magnesites which give decidedly less dry strength to the product. It is essential that the deck covering manufacturers study the water resisting properties of the magnesites they purchase, for some of them give cements so little resistant to water that trouble is almost sure to result from their use. The Dow Company believes that the cause of the variation lies more in the burning than in the chemical composition of the magnesite. Commercial products can be secured which give cements of very high water resistance, and a study of this one point will greatly lower the chance of failure of composition deck coverings as well as possibly opening the way to a wider field of usefulness.

Wearing Qualities

A composition deck covering should have good abrasion resistance as well as good wearing resistance. The former has to do only with the scratching or marring of the actual surface but depends upon the same factors that affect the wear, with possibly an accentuated effect of the trowelling. Abrasion resistance is also increased by the use of a highly fibrous base or scratch coat, which increases the resiliency of the product. A uniform covering throughout is much to be preferred, however, if working conditions about the ship are going to delay the application of the finish coat of a two-layer job so long that it cannot make a proper bond with the scratch coat, or if the other work being carried on results in getting oil, grease and similar materials on the scratch coat.

The majority of composition deck coverings are designed for resiliency, easy treading and highly finished surfacing qualities; some are made harder with resultant loss in resiliency; and for the maximum amount of wearing resistance there is the oxychloride artificial stone flooring. If woodwork has to be screwed to the composition, it must be made relatively soft, and this can be accomplished without making the material porous.

On account of the impractibility of selecting any one of the types of oxychloride flooring as a standard of wearing resistance for comparison with other coverings, the Dow Chemical Company selected clear, well seasoned maple flooring for this purpose, it being more uniform in its properties than any other readily available flooring. Rating this at 100 they found by careful test the following relative immunity-to-wearing values:

Oxychloride heavy duty flooring (average of 8 prepared samples)	414
Hard white porcelain tile (mosaic)	233
Common red tile (hard, unglazed)	164
Inlaid linoleum (best grade)	147
Inlaid linoleum (medium grade)	113
Semi-hard oxychloride flooring (average of 4 submitted samples)	103
Hard maple flooring	100
White oak flooring	88
Asphalt mastic	73
Hard yellow pine flooring	63
Oxychloride composition flooring (resilient type)	
Average of seven submitted samples	51
Average of ten prepared samples	47
Portland cement (1:1 mix)	43
White marble slab	28
Alberene stone	16
Portland cement (1:2 mix)	14
Portland cement (1:3 mix)	11
Printed linoleums	1 to 10

The prepared samples of composition were of a flooring mix which closely approximates the average properties of the usual commercial composition deck covering. They were made with magnesites of normal setting time and tested at fourteen days' age.

There is no dependable relation between wearing resistance and tensile strength. It would therefore seem advisable for deck covering manufacturers to add a comparative wearing test of some kind to the other physical tests they make of their product.

The wearing resistance of the average deck covering is roughly proportional to the amount of magnesite in the mix. It is therefore dangerous to lower the magnesite content for the purpose of economy. Compositions designed for hardness rather than for resiliency may, however, have much greater wearing resistance than the average deck covering notwithstanding a much lower percentage of magnesite.

Some floors are found to resist wear more than twice as well as others when the only difference in them is the particular magnesite used.

The nature of the fiber used has a bearing upon the wearing resistance. It is commonly recognized that wood fiber gives the more resilient flooring while asbestos fiber imparts the greater hardness and wearing resistance. The Dow Chemical Company has found, as averages of several tests of each kind of fiber in the standard flooring mix, the following interesting effect of fiber variation:

	Relative Immunity with Hard Maple Flooring as 100
Asbestos, long fiber	61
Asbestos, medium fiber	55
Asbestos, short fiber	47
White pine sawdust	50
White pine wood flour	42
Hard maple sawdust	40
Hard maple wood flour	31
Oak sawdust	45
Oak wood flour	41
California redwood sawdust	43
California redwood wood flour	38
Granulated cork	56
Cork flour	50
Hard yellow pine sawdust	43

The Dow Company considers the relatively high value of the white pine fibers as compared with the wearing resistance of white pine boards to be due to the fibers being insecurely bound in the board form. The wood flour fibers are 1/3 to 1/10 the size of the sawdust fibers, present a very much larger surface to be covered by a given amount of binder, and are thus less firmly held.

Upon investigating the effect of aggregate variation upon the wearing qualities the Dow Company ascertained the following:

Fine Aggregate	Relative Immunity with Hard Maple at 100	Tensile Strength
3 Powdered silica : 1 talc : 1 pigment	43	625
3 Powdered marble : 1 talc : 1 pigment	36	592
3 Powdered limestone : 1 talc : 1 pigment	35	606
3 Powdered Kieselguhr : 1 talc : 1 pigment	27	452
3 Powdered silica : 1 China clay : 1 pigment	65	703

This illustrates the unreliability of the tensile strength as a gage of the wearing resistance. That chemical composition is not the determining factor is also shown because Kieselguhr, or diatomaceous earth, is identical chemically with silica, both being silicon dioxide. The former, however, is much the softer. China clay shows up very well, but may have disadvantages in other directions which offset this good showing.

Solution strength is a big factor in developing a wear resistant composition deck covering. There is a very great increase in resistance to abrasion with an increase in the chloride strength from 16 degrees to 22 degrees, but little or no gain in this direction from the use of solutions above 24 degrees Baumé. A deck covering made with solution of low strength will wear three times as rapidly as one made with 22-degree solution. The greater loss in strength when wet, before referred to as a result of using weak solutions, results also in excessive wear.

Upon investigating the effect of stiffness of the mix upon the wearing qualities the Dow Company ascertained the following:

Consistency	Relative Immunity with Hard Maple as 100
No. 16 supporting 250 grams on 1 inch diameter surface	47
No. 20, supporting 250 grams on 1¼ inch diameter surface	46
No. 24, supporting 250 grams on 1½ inch diameter surface	43
No. 32, supporting 250 grams on 2 inch diameter surface	42
No. 48, supporting 250 grams on 3 inch diameter surface	37

It is evident that the tendency of inefficient workmen to mix the material too thin should be carefully guarded against.

Upon investigating the claim of the deck covering manufacturers that by a proper trowelling procedure a superior wearing product could be obtained the Dow Company ascertained the following, which amply justifies the claim:

Surface Treatment	Relative Immunity with Hard Maple as 100
1. Strike-off and immediate smoothing without any subsequent surface finishing	30
2. Strike-off, smoothing, and a moderately heavy trowelling at or about initial set	45
3. Same as (2) but with an additional heavy trowelling at about the final set	46

It appears from these figures that about 50 percent improvement in the resistance to wear is developed by the use of proper trowelling as against no surface finishing after the first smoothing; also that the second trowelling is of little or no value. Materials which set so fast that they cannot be properly trowelled and have to be finished off by rubbing with wire wool probably come in the class of the test (1) product.

The use of a properly designed machine mixer will result in increased wearing qualities as against the best hand mixing. Such use should also result in reduced labor costs.

For heavy duty service the Dow Company recommends a special mix containing silica sand when trowelled to a smooth top surface the hard silica sand grains present a very high wearing resistance and they are so firmly bound by the oxychloride cement that they are not, like the sand in most Portland cement floors, dislodged by the abrasive action of traffic. Such a mix shows an average wearing resistance four times that of hard maple and from eight to nine times that of the average composition deck covering of the resilient type. Its cost should be considerably less than the latter and be only a little above that of the best Portland cement flooring. It is questionable if this would be found to have sufficient toughness for shipboard use except in small areas; but there is a good field for a wear resistant material for spaces that are at times used for accommodations and at other times for cargo, and this may be a suggestion to that end.

(*To be continued.*)

American Shipping Service to the Philippines Adequate

THE Shipping Board has adopted a resolution certifying to the President that the American shipping service to and from the Philippines and other island possessions, with the exception of the Virgin Islands, is adequate, so that the President may issue a proclamation extending the coastwise laws to that service. As to the Virgin Islands, the board certified that the service would be adequate on 90 days' notice.

Ship Control on Modern Battleships

Communication and Signal Systems Handled by the Bridge Officer When He Takes the Deck at Sea

By Lt. Comdr. Alex. M. Charlton, U. S. N.

THE activities of a modern man-of-war may be separated under two general heads, fire control and ship control. Fire control includes the entire system of directing the offensive weapons of a vessel including material, personnel, methods and organization. Ship control comprises the entire system of maneuvering the vessel, the upkeep of the hull structure and the maintenance of water-tight integrity including the material, personnel and organization to obtain these objects.

The problem of handling vessels as large as our modern battleships in cruising formation requires the most accurate and rapid means of controlling the engines and steering gear possible. When it is considered that vessels cruise at a distance of five or six hundred yards from foremast to foremast the amount of open water between the stern of one vessel and the bow of the vessel astern of her seems almost negligible. To maintain accurate distance necessitates a fineness of control that would make the average merchant skipper very nervous.

Closed Type Pilot House

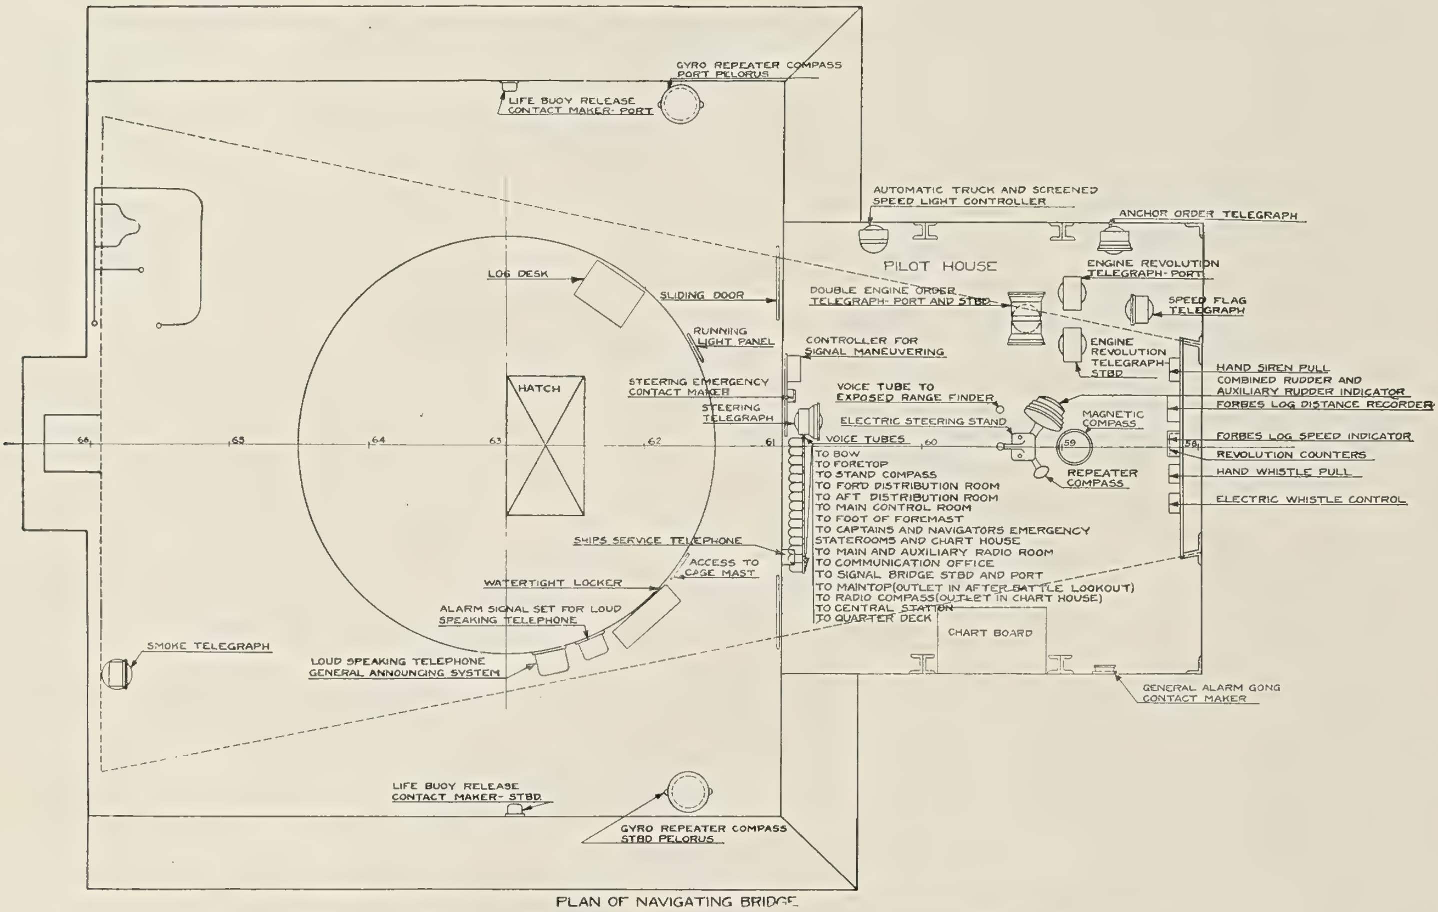
The experience of the Navy with North Atlantic weather conditions in winter led to the adoption of the pilot house type of bridge which can be completely closed in inclement weather. This in itself is a considerable advance over the old type of open bridge which caused the personnel on the bridge an untold amount of suffering in winter weather.

Steering System

Our vessels today are steered electrically, the steersman using a controller quite similar to a street-car controller. A man no longer stands a trick at the wheel, for there is no wheel. This controller operates a motor in the steering compartment which controls the movements of a hydraulic (oil) motor. Enough power is furnished to put the rudder from hard-over right to hard-over left rudder in twenty seconds. The position of the rudder at any instant is shown by the rudder indicators mounted on one side of the steering stand. One of these indicators is of an ingenious electric motor type in which a pointer is moved to the rudder angle by means of contacts made at the rudder head. The other indicator is of the lamp type in which a lamp is lighted behind the figures showing the rudder angle. The two systems are enclosed in the same case and work simultaneously, one as an auxiliary for the other.

In case the steering gear in the pilot house is broken down, a steering telegraph enables the proper directions to be sent down to the steering room at the stern of the vessel. This is a motor type telegraph.

Gyroscopic compasses determine the course of the vessel.



Plan of Navigating Bridge Showing Location of Communication and Signal Appliances

The master compasses are down below armor with connections to the repeater compass mounted on the steering stand. There is also a steering magnetic compass mounted in a binnacle just forward of the steering stand.

The standard magnetic compass is mounted on a platform high up in the foremast where it will be as free from the magnetic influence of the steel of the vessel as possible.

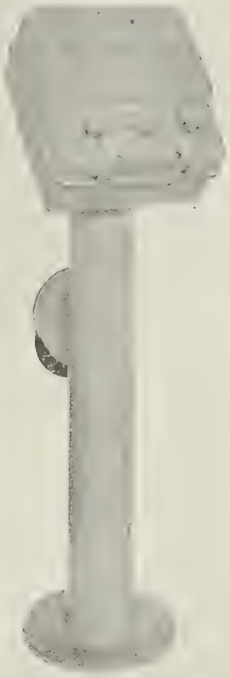
Engine Telegraphs

Engine order telegraphs are mounted on pedestals on the port side of the pilot house and arranged so that the transmitting handles point forward when the engines are going ahead and aft when the engines are going astern. These telegraphs are of the electric synchronous motor type and convey to the main engine control how the engines are to be moved.

Close to the engine order telegraphs are mounted the engine revolution telegraphs. These telegraphs transmit the revolutions desired at any time. They are of the motor type and will transmit revolutions by units from 0 to 299. By these telegraphs the engine room is enabled to tell the exact revolutions desired and so control the speed of the vessel to small fractions of a knot.

Rudder Indicator Motor Type

Electric Engine Order Telegraph Transmitter



Course Telegraph Transmitter Indicator

Automatic Truck and Screened Speed Light Telegraph Transmitter

When a vessel finds it necessary to change its speed in formation this information must be transmitted to the vessel astern so that she may be handled to avoid the possibility of collision. Small flags which indicate a vessel's speed in knots are displayed from the signal bridge below the pilot house level. The pilot house informs the speed flag station what the speed in knots is at any time by means of the speed flag telegraph, another motor type instrument. On the forward bulkhead of the pilot house are arranged a speed indicator and a distance recorder operated electrically from a small revolving shaft, which protrudes through the bottom at the pivoting point of the vessel. As this instrument is not connected with the propellers it gives the vessel's speed and distance run irrespective of the slip of the propellers, condition of bottom or the state of wind and sea. The indicator gives the speed in knots and the distance recorder gives the distance traveled in miles and tenths of a mile.

Revolution Counter

Alongside of the speed indicator are revolution counters actuated electrically from the propeller shafts. These counters do not give the instantaneous speed of the engines, but by cutting in a pointer and letting it run for thirty seconds or a minute the propeller speed may be obtained.

Distance Recorder

Speed Indicator

Whistle

Controls for the hand siren and the hand and electric whistles are also located on the forward bulkhead of the pilot house.

Speed Signals

For advising other vessels of the fleet what one's engines are doing a system of speed cones is employed by day, the various positions either with the apex of the cone up or down telling what speed the engines are making and their direction. At night a light is displayed at the main truck, white for ahead and red for astern. Pulsations of this light tell the speed of the engines. An automatic truck light controller is installed in the pilot house, which, upon placing the pointer at the proper indication, will automatically show the desired signal on the truck light.

Voice Tubes

Voice tubes are led from the pilot house to the standard magnetic compass in the mast, to the bow for handling the anchor gear, to the electric distribution rooms, to the engine control room, to the quarter deck, to the captain's and the navigator's emergency staterooms and the chart house, to the foot of the foremast, to the radio rooms, to the signal bridge, to the range finder on top of the pilot house, to the radio compass, and to the communication office. These voice tubes are fitted with call bells and supplement the ship's service telephone system and the maneuvering telephones with which communication may be had to nearly all the stations above mentioned.

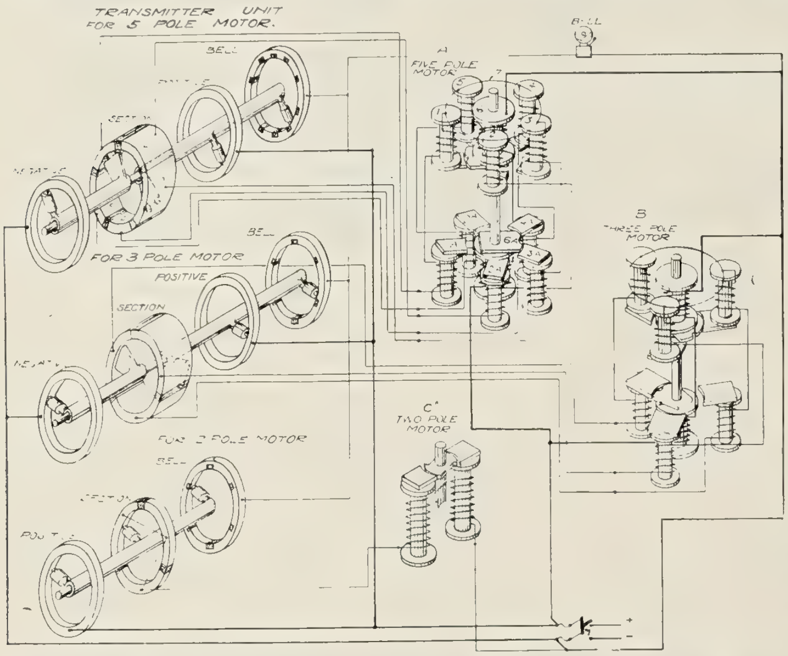
Pelorus

On the bridge outside of the pilot house are two gyro repeater compasses installed in pelorus stands, one on either side. These compasses are fitted with azimuth circles and

alidades for taking bearings. Each stand also carries a bracket in which may be mounted a small range finder for taking distances in formation and other small ranges. It is quite essential that the distance to the ship ahead be known at all times in order that the engines may be kept at the proper speed to maintain the standard distance. A stadimeter, the invention of Rear Admiral Bradley A. Fiske, U. S. N., is also furnished vessels for measuring distances. This instrument measures the angle subtended by the masthead height above the waterline. Knowing this height, the stadimeter is calibrated to read in yards. An adjustment is fitted for setting various masthead heights.

Life-Buoy Releasing Gear

On either side of the bridge are two life-buoy release keys which enable the Franklin life-buoys on the quarters to be let go from the bridge. These electric keys operate the solenoids of the release mechanism at the buoys.



Elementary Wiring Diagram for Electric Telegraphs, Rotary Type

Lights

A running light panel which controls all the running, anchor and peak lights is mounted on the cage mast.

The running lights comprise the side, masthead and towing lights, range light, stern light, steering light, wake light and screened speed light. The steering light is a minute light mounted on the jack staff for use in making turns in formation at night. The wake light shines down on the wake immediately astern of a vessel and gives information to the vessel astern when changing course.

Anchor lights comprise the forward and after anchor lights, the boom lights and the gangway lights.

The peak lights comprise the absentee lights, man-of-war lights, breakdown and man-overboard lights, and the flag lights. Absentee lights are white lights arranged one over the other abaft the mainmast and vary in number from eight for the President of the United States to one for the captain of a vessel. They indicate that the official or officer is ashore but will return within twenty-four hours. Man-of-war lights are two vertical white lights shown when a man-of-war is approaching an anchorage and displayed by anchored men-of-war when seen on an incoming vessel. Breakdown lights are two vertical red lights displayed by a vessel in formation when she is out of control. When the upper of these two lights is pulsated it indicates man overboard. Flag lights are two horizontal white lights displayed abaft the mainmast and indicate the presence of a flagship.

Telephone System

On the cage mast is a transmitter for the general announcing telephone system. This telephone allows orders, bugle calls, etc., to be transmitted throughout the vessel and announced in the various compartments. A buzzer of a peculiar tone is also fitted in this system as a signal for closing watertight doors.

At the rear of the bridge is the smoke telegraph by which the firerooms are notified to make smoke for screening purposes or to stop making smoke.

Anchor Telegraph

The great distance from the bridge to the bow on our new vessels has caused the installation of an anchor telegraph. This enables the bridge to signal the boatswain at the bow when to let go and how much chain to ride at and also to ask questions and receive answers concerning the ground tackle.

Docking Telegraph

On top of the pilot house are two docking telegraphs which signal electrically to the deck aft how to handle lines in coming alongside a dock.

A large range finder is also fitted on top of the pilot house for taking long ranges. A voice tube leads to the pilot house.

Signals

On the signal bridge are the racks for signal flags with halyards leading to the foreyard arms. Blinker signal keys are also installed here for operating the blinker lights at the ends of the yard-arms. Signals are sent using the Morse code, the keys being arranged like telegraph keys. The circuits are arranged so that the same signal may go out from all four blinker lights or four different messages may be sent simultaneously.

Searchlights

Two 24-inch high-powered signal searchlights are placed on the signal bridge for distant signalling. They are fitted with signal shutters so that signals may be transmitted by the Morse code. Two 12-inch portable searchlights are also provided for short range signalling.

Synchronous Type of Motor Employed

So many instruments of the synchronous motor type are employed that it may be interesting to describe the action of this type of motor. The elementary wiring diagram shows typical layouts with a transmitter and an indicator at each end for five, three and two pole motors. The indicator consists of magnets arranged equidistantly about a polarized armature which is free to rotate under the action of the magnets as the latter are energized from the transmitter. The latter is arranged so that as the handle is moved from one indication to another the circuits to various magnets in the indicator are completed and the indicator armature is pulled around to correspond to the transmitter indication. When the transmitter handle is moved a bell is rung at the indicating station. This type of motor is also made to indicate twenty positions with five poles by reversing the polarity of the fields and varying the number of poles energized at a time. Very little trouble is experienced with this type of motor when properly made, as it is self-synchronous and so cannot get out of step, takes little power and is very reliable. Most of the instruments of this type used in the Navy are manufactured by Charles Cory and Son under their various

(*Continued on page* 202.)

Application of Lubricants*

Where and How to Apply the Lubricant on Marine Machinery

Of equal importance to the selection of oils is the reliability of their method of application. There is a close relationship between the conditions under which an oil must serve its purpose, and the manner in which the oil is applied to the parts to be served. The various methods or systems by which oils are applied to the internal parts, generally termed cylinder lubrication, are as follows:

Hand Oiling.—Oil is applied by hand at intervals by means of an oil can, a hand oil pump or an oil swab or grease is applied through specially designed cups or by hand.

Drop Feed Oiling.—Oil contained in individual drop oilers is supplied at a regulated gravity action. The air compressor oil cup automatically supplies oil by air compression pressure.

Splash Oiling.—Oil contained in an enclosed chamber is splashed to parts requiring lubrication by the dip of a moving part of the machine.

Hydrostatic Lubricator.—Oil contained in a lubricator is discharged through an oil feed pipe by water displacement. The water is obtained from steam condensation.

Mechanical Force Feed Lubricator.—Oil contained in a lubricator is forced to the moving parts by one or two plunger pumps driven off some moving part of the engine or machine.

Knowledge of your lubrication problem will show the need of the proper method of application to suit the requirements of your special type of equipment.

Cylinder Lubrication

For the internal lubrication of:

(*a*) Steam engines and pumps;
(*b*) Diesel engines;
(*c*) Surface ignition oil engines;
(*d*) Air compressors;
(*e*) Refrigerating machines.

Steam Engines and Pumps

Cylinder lubricants are applied by the following systems:

(1) Oil cups (formerly known as "tallow cups");
(2) Hand oiling, i. e., swabbing the piston and valve rods;
(3) Hand pumps;
(4) Hydrostatic lubricators;
(5) Mechanical force feed lubricators.

(1) Oil cups, usually made of brass, some with two plug cocks, others with a screw top cover with one valve at the base, are attached on the top of cylinder or valve chest covers. The cup is filled with cylinder oil and then closed; and by opening the cock or valve at the base of the cup, the oil is permitted to flow into the cylinder or steam chest, as the case may be. This method is unsatisfactory, for it is spasmodic and wasteful, in that it requires too much attention.

(2) Hand oiling, swabbing the rods with cylinder oil, serves a lubrication purpose as far as the rods and rod packings are concerned, but this method of application is not satisfactory for cylinder and valve lubrication. Here again, the lubrication is spasmodic and uncertain, with the possibility of comparatively large doses of oil going out with the exhaust steam, which is the *main thing* to be avoided in marine practice.

(3) Hand oil pumps are sometimes installed, for use when starting an engine, and also when the engine is operating and there is a tendency for any of the internal parts to squeak or groan, as sometimes happens. But the hand oil pump is dangerous in the hands of a novice, because of the temptation to pump in more oil than is actually required, with the result that the excess oil goes out in the exhaust steam to the condenser. When it is found necessary to use the hand pump, judgment and care must accompany its use.

(4) The hydrostatic lubricator is one commonly used for the internal lubrication of marine steam engines. The lubricator is connected to the main steam pipe by suitable piping and valves. The principle of operation is as follows:

The body of the lubricator is filled with oil. Steam enters the condenser at the top of the lubricator, and is condensed. The interior construction is such that the condensed steam falls to the bottom through a small internal pipe. There is a pressure in the lubricator due to the pressure of steam in the main steam pipe, and an additional pressure due to the head of water in the condenser and piping above the body of the lubricator. The counter pressure at the outlet connection of the lubricator, into the main steam pipe, is that due to the pressure of steam in the main steam pipe. It is the unbalanced pressure due to the hydrostatic head, together with the fact that oil is lighter than, and floats upon, the water of condensation collected in the oil container, which causes the oil to rise and overflow into a small discharge pipe connected to the feed control valve at the base of the sight feed glass.

By the adjustment of the control valve, the oil is fed drop by drop at a certain rate, proportional to requirements for any given case. As the oil is used the water of condensation accumulates, until the body of the lubricator is emptied of oil, and becomes filled with water. The water is drained out and the lubricator refilled with oil, and the same cycle of operations is repeated.

The hydrostatic lubricator is not automatic in action, because it must be started and stopped by hand. Neither is it absolutely regular and uniform in its delivery of oil, as changes in temperature of the surrounding air, leakage or a slight obstruction in the small delivery tube passage will change the adjusted rate of feed, and in some cases the feed will stop. The hydrostatic lubricator requires close watching for best results.

(5) The mechanical force feed lubricator is essentially a small plunger force pump, contained in an oil reservoir, and driven by a lever and ratchet motion, actuated by some moving part of the engine. It is automatic, absolutely regular and sure in the delivery of oil, and its stroke may be adjusted to deliver within its range any desired quantity of oil in any period of time. Temperature changes have no effect whatever with this type of lubricator, and when once adjusted it requires no further attention other than to replenish the oil.

For best results, an atomizer is used with the force feed lubricator. The lubricator may be attached to any convenient part of the engine, and a pipe connection made to the main steam pipe, at a point a few feet back from the engine stop valve with a non-return check valve located at each end of the oil pipe. This point of connection is chosen in order to give the steam rushing through the pipe an opportunity to break up the drops of oil delivered through the atomizer. Thus the steam carries the oil in spray form to all internal moving parts of the engine. With a correct adjustment of the pump plunger, not any more oil than is actually required for lubrication will be delivered.

With this type of lubricator, a perfect control of the feed

*From *The Compass*, published by the Vacuum Oil Company, New York.

is attainable at *all times,* and delivery of oil takes place only while the engine is operating.

The steam cylinders of auxiliaries and pumps are supplied with lubrication in the same manner as that described for the main units. The usual method in marine practice being by swabbing the rod, although the hydrostatic lubricator is sometimes employed.

Diesel Engine

Cylinder lubricants for Diesel engines are applied by the force feed method, in which the mechanically operated force feed lubrication, already described, is employed. The lever movement may be actuated by an eccentric on the cam shaft, or receive motion through connection by a driving rod attached to some moving part of the engine.

The cylinders are lubricated by providing multiple force feed pumps with feeds to supply all the cylinders, one plunger for each cylinder and one plunger for each air compressor cylinder. In some engines, two, three or four plungers for each cylinder are provided, separate oil leads being introduced at different points around the cylinder. In some instances the supply from one plunger pump is applied to an oil pipe encircling the cylinder having 2, 3, or 4 leads. With this arrangement it is possible that the oil supply may be unequally distributed, and lubrication will be deficient; therefore, one lead from each pump to each cylinder may be considered the only reliable practice. Check valves are placed in the outlet end of each oil lead in order to maintain a full oil pipe. The leads should be so placed and connected that oil will be fed between the first and second piston rings when the piston is at the bottom of its stroke.

Surface Ignition Oil Engines

Oil is supplied under pressure from a mechanically operated force feed lubricator in which there are a number of small independent plunger pumps, each having a pipe or tube to conduct the oil to the desired point of introduction in the several cylinders. It is desirable to have these leads supply one point only, i. e., not branched to two or more points, because it is uncertain that the division of the supply of oil in such cases is equal.

Oil should be supplied to the piston of large engines at several points in its circumference and each of the leads should be served by an independent pump plunger in the lubricator. Smaller engines do not need as many points of application. A check valve is placed in each oil lead, as before referred to in Diesel engines. For the best effect, the stroke of the pumps should be timed to deliver the oil between the first and second piston rings at the instant the pistons are at their extreme outward travel (the bottom end of stroke).

Air Compressors

Oil is usually applied to the air cylinders by means of an air compressor sight feed drop oiler attached to the cylinder in a vertical position. It consists essentially of an oil container, a feed regulating valve and a ball check. In operation, the main valve is open wide, admitting air pressure to the container, and the regulating valve is adjusted to the desired rate of oil feed. The oil thus admitted to the cylinder is distributed over its walls and the frictional surfaces of the valves.

The definite method for supplying cylinder lubrication is by means of the mechanically operated force feed lubricator. The number of feeds required depends upon the size of the compressor. With such a lubricator the oil feed, once adjusted, remains constant and permits regulation for a necessary minimum rate of feed, avoiding the possibility of over-lubricating, which is one of the principal causes for carbonization on the voluntary discharge valves.

Feeding Oil Direct.—As a rule, it is best to feed the oil sparingly, uniformly and directly to the frictional surfaces. In horizontal compressor cylinders, the lubricating oil is usually introduced through one lead at the top and at the center of the cylinder. The oil is spread internally by the moving piston and forms the required complete sealing and lubricating film.

Vertical compressors with single acting trunk pistons may be lubricated by means of the splash oiling system, whereby a moving part of the machine dips into the oil in the crank case, producing an oil spray that reaches all parts. It is of greatest importance that a constant oil level be maintained in the crank case, for if the oil level is too low the oil spray will be insufficient and some of the parts will be "starved." If the level is too high, there will be too much splash and an excessive supply of oil will work past the piston rings and will lodge on the voluntary discharge valves. This will result in the carbonization of the oil under the extreme heat of compression, causing the valves to stick.

Refrigerating Machines

Cylinder lubrication of various types and kinds of refrigerating machines is accomplished by feeding oil to the center of the rod stuffing box. The stuffing box is much deeper than is required for steam engines and contains two sets of packing rings, separated in the center of the depth of the box by what is called the "lantern." The lantern serves a double purpose, namely, it forms a small reservoir for gas that leaks out from the cylinder and also serves as a container for the lubricant. There are usually two pipes connected into the lantern, one for introducing the oil, the other for withdrawing the gas—the latter pipe is connected to the suction side of the machine. In some installations, the oil is fed to the stuffing box by an ordinary sight feed oil cup, or by a small hand pump used intermittently at the discretion of the operator.

For carbon dioxide machines, when high compressor pressures are encountered (1,000 pounds per square inch), the mechanical force feed lubricator is employed. The movement of the rod back and forth, or up and down, as the case may be, carries the oil with it, thus lubricating effectively the rod packing and some of the lubricant is carried into the cylinder of the compressor, lubricating the walls and piston rings at the same time.

It is considered that sufficient cylinder lubrication may be obtained from that which is drawn into the cylinder by the movement of the piston rod, as most of the refrigerants used are somewhat of a lubricating nature, and it is desirable to have as little oil in the system as possible.

Ship Control on Modern Battleships

(*Continued from page* 200.)

patents, although other manufacturers have lately appeared in the field with similar instruments.

The telegraphs are mounted as pedestal or bulkhead instruments. Some are similar in appearance to telegraphs of the mechanical type, and others are made with the transmitter actuated in the face of the instrument.

Conclusion

To keep all of these instruments, lights and call bells in efficient operating condition requires the services of a good many men, but the safety of the vessel is so dependent upon their operating correctly when needed that no effort is spared on their upkeep.

The bridge equipment of a man-of-war may seem too elaborate to an officer in the merchant service, but it is hoped that the foregoing has shown the necessity for all the equipment used.

Relationship of Rail and Water Carriers*

Wide Piers and the Best of Mechanical Devices Needed for Closest Possible Liaison Between Land and Water Carriers

By William J. Wilgus

IN times when an impoverished world is practicing rigid economy as never before it is to be expected that trade between nations will flow along paths of least resistance and hence through those gateways which, other things being equal, exact the least tribute in tolls and time from the rail and water carriers which meet there for purposes of interchange.

Pier a Joint Terminal

The usual pier or quay after all is a joint terminal not only for the ship but likewise for the railroad and for the motor truck. Unfortunately too often this common ground is under the exclusive jurisdiction of one of these agencies, with dire results to the others. For instance, a steamship line in sole possession of a pier will seldom, if ever, provide proper space upon it for tracks on which the railroads may place their cars for delivering and receiving freight direct, when it may dictate to the railroads, without expense to itself, that the interchange shall be effected through the medium of trucking or of floating equipment with its added cost of breaking bulk and of tortuous waterfront and marine operations. This is the situation that obtains today in our greatest port, New York, originally brought about by natural conditions that ante-dated the railroad era, and later perpetuated through the provision in the seaboard rate that requires the railroad to interchange freight at shipside rather than at the end of the rail-haul.

> **The unification of the management under joint control, of rail and water terminals in the waterfront zone of each port is essential to a full solution of the port problem. With this should go a coordinating belt line under the jurisdiction of the port management; an "open door" for the vast fleet of independent craft that is unpossessed of exclusive facilities —leased or owned; and working arrangements with the trunk lines whereby freight consigned to the port shall be suitably grouped at distant clearing yards for movement direct to the particular location for which it is destined, without the need for intermediate reclassification or breaking bulk. There is much room for improvement through a further restriction of free storage which is now a wasteful burden on the rail carrier. Ample warehouses and open storage areas adjoining the piers and quays, with moderate charges, would go far to decrease this evil.**

The wastefulness of this process can be best illustrated by comparing it with the confusion, delays and excessive costs that would reign in a joint railroad terminal where differing gages of the main lines and yard tracks would make necessary the breaking of bulk or transfer of car bodies in transit, within sight of final destination, a condition too absurd for serious consideration.

Wide Piers Necessary

The remedy for this manifestly unhappy situation lies in the converting of port authorities and carriers, both rail and water, to the wisdom, or rather strict necessity, of abandoning the stingy pier policy and of building generously proportioned wide piers and quays on which there shall be ample space for transit and storage sheds, motor truck driveways and track layouts designed for continuous cargo handling uninterrupted by switching operations. All of the great ports of the Old World, and even the principal ones of South America and of our neighbor on the north, Canada, have taken this foresighted course, and in this country the more progressive of our ports have rather timorously done likewise. But there are many of our ports, notably New York, where the narrow pier policy still rules. In planning for the future, then, let us remedy our past faults and substitute wide piers for the inefficient and wasteful narrow, trackless ones which we have inherited from the days of the sailing ship and canal boat.

Another direction in which there is a burning need for improvement is the more extended employment of mechanical equipment for reducing the expense of cargo handling and for expediting the release of ships and cars.

For example, in the World War the American Army in France operated in from twenty to thirty ports at which in the last month of the war, November, 1918, were discharged, by a variety of methods, nearly a million tons of supplies at an average rate of 449 tons per ship per day, or approximately one and one-tenth tons per lineal foot of ship berth per day. At one of these ports, American Bassens, there had been completed at that time a partial installation of electric gantry cranes which despite many handicaps, such as untrained operators, poor lighting facilities, shortage of cars and stevedores and insufficient "tuning up," made an average record of 717 tons per ship per day, equal to one and eight-tenths tons per lineal foot of ship berth. This was in marked contrast to the 371 tons per ship, or nine-tenths of a ton per lineal foot of ship berth, discharged daily at the neighboring berths where the non-completion of the gantries made necessary the handling of similar cargoes by ship tackle not only with less speed but also with greater damage to the supplies, and with much more rehandling between ship, car and shed by reason of the shorter radius of action of the ship tackle.

A Job for the Shipping Board

Relief in all these particulars would appear to be hopeless unless some competent central governmental agency, clothed with power, shall vigorously take up the problem in all its phases, commercial and military, with the determination promptly to find and enforce the application of remedies. It is idle to expect that the ship interests and the many railroads will make any substantial united progress in that direction.

Under Section 500 of the Transportation Act of 1920 the

*Paper presented before the American Society of Civil Engineers

duty is placed upon the Secretary of War to investigate this very problem in harmony with the declared policy of Congress "to promote, encourage and develop water transportation service and facilities in connection with the commerce of the United States, and to foster and preserve in full vigor both rail and water transportation." Along with this it is the duty of the Interstate Commerce Commission in the interest of the country at large, now called upon to underwrite the return on railroad investments, to look into and correct matters that affect the operating expenses of the railroads which are burdened with much of the wasteful practices at our ports, from which waste the water carriers, often flying a foreign flag, are reaping benefit. Then it should not be forgotten that as a people we are vitally interested in the provision of efficient ocean port terminals for our gigantic merchant marine, as to which it is the duty of the Shipping Board to take action.

LETTERS TO THE EDITOR

Wear of the Teeth of Marine Turbine Reduction Gears

The writer has read with keen interest Mr. F. W. Dean's letter under the above title in the February number of Marine Engineering and Shipping Age and agrees with Mr. Dean that it is unfortunate that such refined workmanship is necessary on marine reduction gears.

However, in view of the fact that friction is always the cause of wear regardless of what the material, whether the hardest diamond ever found or the softest lead, we may as well take it for granted, right now, that there will *always* be wear in reduction gears whether made for marine use or for stationary service. As soon as wear is eliminated, according to the writer's viewpoint, we will have a transmission efficiency of 100 percent.

One way to get around the wear evil, to be sure, is to eliminate gears altogether and use the electrical reduction method, but, no matter what the extent of the development of the electrical method, it is quite likely that there will always be a demand for and a field for the geared method.

There are several reasons why the herringbone type of gear is so popular—reasons why, probably, no better gear reduction method will ever be developed. The slanted tooth is less noisy than the straight line tooth. When the De Laval geared turbine first came out the writer remembers that a great hullabaloo was made about the noises generated in addition to the power. It was claimed by some engineers at that time that the reduction gear would never be a success on account of the noise feature alone. The slanted tooth is also stronger than the straight line tooth—not so liable to break off. A tooth is only a cantilever beam. By relieving this beam of shock, as is done by slanting the beam, the breakage danger is lessened. Also, the end thrusts are taken care of, alinement collars and bearings becoming automatically eliminated.

This latter advantage is considered a disadvantage by Mr. Dean and it doubtless is a disadvantage in the matter of wear, but I cannot see that conditions would be bettered by making the teeth straight as far as wear is concerned. Let us assume that with straight tooth reduction gears ample room would be allowed for side-play. After the very first day of usage we would have some wear because there would be some friction. Then we would move the pinion over one-half inch to prevent the pinion from "wearing a groove for itself" in the large intermeshing gear. However, even after the first day we would no longer have a "perfect fit" nor as good a fit as was had on the first day because a part of the large gear would be used that was not worn on the previous day and that part would place greater pressure on the pinion tooth end than was encountered during the entire first day. Consequently the ends of the pinion would wear down first and regardless of sliding back and forth to "even up" the wear we would find the pinion "wearing a groove for itself."

In talking to a large user of reduction gear turbines not long ago that user remarked: "No matter how accurately the gears are machined they'll never get away from the fact that steel is elastic, that all kinds of metals are elastic, and that the elasticity is great enough to throw all of their wonderful *theory* into the scrap heap." He may have exaggerated the case a bit, but there is a "mountain" of truth in what he said nevertheless.

As for making the large gears out of cast iron and the pinions out of steel, that sounds plausible to the writer. I do not know why it is not done nor do I know if it has been tried on high power reduction drives.

New York. N. G. Near.

The Future in the Shipbuilding Industry

The Armament Conference and its results while canceling many valuable contracts are only part of the reaction expected in the munition and allied trades by every reasonably thoughtful engineer after the war came to an end. It is a natural and not an abnormal condition. Whatever may be said of the great and acknowledged evils of militarism like everything else they had certain compensations. The huge navies of the past have left behind them large industrial plants and produced coaling and repair facilities, charts and other aids to navigation in extended and remote quarters of the world, and their staffs have advanced mechanical construction to perfection by a lavish expenditure on experiments that private enterprise would have been entirely unable to afford.

So much we have as a tremendous legacy today on which to build prosperity in the future.

The world is not bankrupt but its books are tangled up. Its purchasing power as a whole is measured by raw materials for barter and by the needs and numbers of its citizens, which have not been very materially reduced.

The money represented by interest on war bonds goes into some people's pockets and, if the pages of history are an accurate guide to the future, will be spent sooner or later in such luxuries as trips to Europe, yachts, and in permanent investments. There is possibly danger of excessive spending, for unfortunately few can resist the corrupting influence of wealth as experience has shown in both ancient Rome and modern India.

We desire a mercantile marine. Canal dues are complicated by treaty stipulations and subsidies confronted with political difficulties. If tourists were compelled to return in our own ships to obtain entry, it might help things somewhat. Also where there is no probability of displacing American labor our otherwise idle shipping might operate between Asiatic ports with Asiatic crews as the only method of competing with foreign vessels employing Lascars.

Vallejo, Calif. C. E. Burnley.

A Correction

In the article describing the American motorships *Californian* and *Missourian,* published in our February issue, it was erroneously stated that the steering gear was furnished by the Hyde Windlass Company. The electro hydraulic steering gear installed on both the *Californian* and *Missourian* is the A-E-Co Steerer furnished by the American Engineering Company of Philadelphia. The windlasses on both these vessels were also furnished by the American Engineering Company.

Questions and Answers for Marine Engineers

Inquiries of General Interest Regarding Marine Engineering and Shipbuilding Will Be Answered in This Department

Conducted by James L. Bates

This department is maintained for the service of practical marine engineers, draftsmen and shipbuilders. All inquiries should bear the name and address of the writer. Anonymous communications will not be considered. The identity of the writer, however, will not be disclosed unless the editor is given permission to do so.

Is Superheated Steam a Perfect Gas?

Q. (1149).—I am informed that steam heated to 1,000 pounds is nearly a perfect gas. Is there any sense to that statement?

A. (1149).—Such information as is available seems to indicate that at high degrees of superheat and pressure the characteristics of steam approach those of a perfect gas.

Probable Earnings of the Leviathan

Q. (1150).—Can you furnish information as to the probable earnings of the ex-German steamship *Leviathan* in case she were reconditioned and put into the Atlantic passenger service?

A. (1150).—Conditions in the Atlantic passenger trade are somewhat unsettled at the present time, owing to the world-wide business depression and to the readjustment which is taking place on both sides of the Atlantic. The following information, which is quoted from the Atlantic Coast Shipbuilders' Association Bulletin for January 27, 1922, is believed to give as satisfactory a statement for your purpose as is possible under the conditions:

"The probable gross earnings of the *Leviathan* would be $500,000 a voyage, against disbursements of $350,000 per voyage, according to an official of the Emergency Fleet Corporation, figuring out to a net earning of $150,000 per voyage. The figures are based on filling, on the average, of one-third of her total passenger accommodations throughout the year, on carrying a certain rate of mail and on certain other sundry earnings from baggage and so forth. The same official said she ought to earn $150,000 a voyage for fourteen voyages a year. He points out that there must be taken into consideration deductions from net revenue of $250,000 for dry docking and lay-up cost, interest at 5 percent and depreciation. Reconditioning cost of $6,697,303, $1,502,697 for trial trip, insurance and inspection would amount to $1,206,666 annually."

Thickness of Shell Plating in Shallow Draft Vessels

Q. (1151).—What do you regard as the considerations governing the thickness of shell plating in vessels built for use in shallow water?

A. (1151).—In vessels of this class draft and therefore, weight of structure are of the first importance. If the vessel is to be restricted in its use to the inland portions of rivers, the provision against local damage such as grounding and the necessary allowance for corrosion, would be important considerations, both of which are antagonistic to extreme lightness of plating. The character and distribution of cargo and the conditions of navigation, such as current, obstructions, etc., should also be studied. If, however, the vessel is to be used in the mouths of large rivers or along the coast where heavy swells may be encountered, it is necessary to consider the effect of waves upon the ship girder. In this case, in addition to the considerations mentioned above, the ratio of frame spacing to plate thickness is important. The value of this ratio in certain cases with which the writer is familiar may be obtained from the following table:

Ship No.	Length, Feet	Frame Spacing, Inches	Plating Thickness Midships	Ratio of Frame Spacing to Plate Thickness
1	144	18	.22	82
2	176	20	3/8	53
3	167	18	1/4	72
4	200	18	5/16	57
5	160	20	1/10	200

The last ship, No. 5, is a war vessel and represents an extreme which it would be unwise to approach in commercial practice.

Professor Hovgaard in his "Structural Design of Warships," under the heading "Longitudinal Strength," presents a discussion on the subject of bending which is of value in connection with the above.

Pitting of Shafting and Hull Plating

Q. (1146).—We are troubled with pitting of shafting and plates on hulls tied up at our piers, which we attribute to "electrolysis." Can you give us some information on this sort of trouble or recommend some literature pertaining to it?

A. (1146).—The information given is hardly sufficient to permit of more than a very general reply.

In practice that part of the propeller shaft within the stern tube is generally covered with brass liners and the tube is always full of sea water. Electrolytic action takes place between the brass and the iron in consequence of which the latter often becomes deeply corroded close to the end of the liners. On this account United States naval practice formerly required the fitting of zinc plates on the rudder, sternpost, shaft struts and shaft tubes, and zinc rings around composition sea chest openings. The zinc rings now have been superseded by medium steel rings and doubling plates, which serve to provide an excess amount of electro-positive material which can be readily removed when corroded. The use of zinc plates on the rudder, sternpost, etc., has been abandoned generally, since experiment has shown no injurious effect due to their omission.

It is to be assumed, of course, that such precautions as the above have already been taken. If this is the case, it may be that, for one reason or another, the water around your piers contains certain acids which greatly strengthen the electrolytic action. Chemical analysis of a sample might then prove of value.

Comment on the corrosion of metals under varying conditions may be found in the following:

"Corrosion and Preservation of Iron and Steel" by Cushman and Gardner.

"Practical Shipbuilding" by Campbell Holms, Edition 1918, Vol. I, Articles 566 and 569.

"Shipbuilding Cyclopedia," Edition 1920, Dictionary Section, under the term "Wrought Iron."

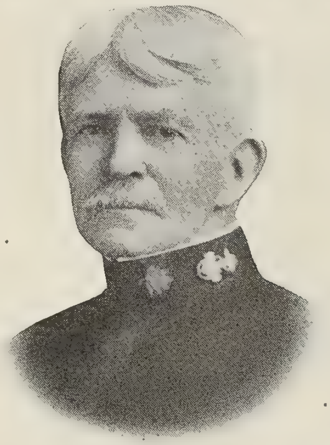
PERSONAL MENTION

Joseph W. Powell, president of the Emergency Fleet Corporation, has resigned his connection with the corporation to take effect this month.

Rear Admiral Robert S. Griffin, U. S. N. (retired), has recently become associated with Commander William L. Cathcart, U. S. N. R. in marine and naval engineering consulting work at 149 Broadway, New York. Until his retirement in September, 1921, Admiral Griffin had been for about eight years Engineer-in-chief of the Navy and Chief of its Bureau of Engineering (formerly Bureau of Steam Engineering). In addition, he had been for nearly five years previously, Assistant to the then Engineer-in-chief, so that his intimate association with, or personal direction of the technical and financial affairs of this most important Bureau have covered a continuous period of more than thirteen years, during which every combatant vessel now in our Navy was either designed or built. This period also covered the duration of the world war in which our Navy grew to a strength of 600,000 men and had nearly 2,000 vessels of all classes in commission, of which eventually we had in European waters a total of 338 ships, carrying 5,000 officers and 70,000 enlisted men. To the tireless energy of Admiral Griffin and his staff, at Washington and in our various Navy Yards, is due the fact that, throughout the whole war, no major vessel of the Navy was ever delayed by repairs to her machinery. An outline of the Bureau of Engineering's field prior to and during the war will give some conception of the magnitude of this work. That field covered all steam, all electrical and all internal combustion engines for the propulsion of naval ships; the bulk of the electrical apparatus for surface ships, submarines and aircraft; the machinery for aircraft; the generation and supply of gas for observation balloons and dirigibles; and finally extended radio telegraphic work in the design and supply, during the war, of the entire wireless equipment of all shore stations in the United States, in our island possessions and on every vessel, merchant or naval, flying the American flag. On September 1, 1921, all aircraft equipment—machinery, electrical apparatus and balloon gases—was transferred to the new Bureau of Aeronautics. Admiral Griffin was born at Fredericksburg, Va. He was educated in the private schools of that historic town and at the U. S. Naval Academy. After graduation at Annapolis in 1878, his early years in the Navy were spent in engineering duty afloat and ashore. His sea service ended in 1905, when he was acting as Fleet Engineer of the Atlantic Fleet, an assignment which had followed a similar one in the European squadron. From then onward, he served almost continuously in either the design or the construction of naval machinery, until he assumed office as Engineer-in-chief and chief of the Bureau of Engineering. The Admiral was awarded the Sampson Medal for his services in the Spanish-American war and also the U. S. Distinguished Service Medal for his work during the world war. The French Government made him a Commander of the Legion of Honor in recognition of his services to the Allied cause. He was granted the honorary degree of Doctor of Science by Columbia University and of Doctor of Engineering by the Stevens Institute. He is a member of the National Research Council and an Honorary Member of the American Society of Mechanical Engineers.

Rear-Admiral R. S. Griffin, U. S. N.

Commander William L. Cathcart, U. S. N. R., associated with Rear Admiral Robert S. Griffin in consulting work, was educated at the University of Pennsylvania and at the U. S. Naval Academy. After his graduation at Annapolis, he served for sixteen years in the former Engineer Corps of the Navy, afloat and on inspection duty ashore. He then resigned to enter private business. Later he became Adjunct Professor of Mechanical Engineering at Columbia University, then served for some years on the scientific staff of the Babcock and Wilcox Company and is now Professor of Engineering at the Webb Institute of Naval Architecture, New York City. During the Spanish-American war, Professor Cathcart volunteered, was appointed a Chief Engineer in the Navy and was ordered to special duty at the Navy Department in confidential service under Admiral Melville then Engineer-in-chief. At the outbreak of the world war, he again volunteered, was appointed Lieutenant Commander, U. S. N. R., and served at the Navy Department as confidential aide to Admiral Griffin. He remained on this duty for nine months after the war closed. In recognition of his service, he was promoted to the rank of Commander on recommendation of the Board on Selection.



Commander W. L. Cathcart, U. S. N. R.

Captain F. L. Iverson has been appointed to command the new passenger ship *Reliance* of the United American Lines. The *Reliance,* together with her sister ship the *Resolute* was recently purchased by the Harriman interests from the Royal Holland Lloyd Line. These boats will be used to maintain a fortnightly passenger service between New York and Hamburg with calls at French and English channel ports. At the present time Captain Iverson is in command of the United American Line passenger ship *Mount Clinton.* He will assume his new command about the first of March. Captain Iverson took command of his first ship in 1892. This was a foreign going sailing vessel operating out of New York. After seven years on various sailing craft he became associated with the American Line and served with their steamers for about seven years. For nearly ten years he commanded the pleasure yachts of several well known Americans. During the war Captain Iverson was in command of the transport *Liberator.*

Capt. F. L. Iverson

Shipbuilding, Reconditioning and Operation

Port Expansion, Passenger and Freight Activities and Other Notes of Interest in All Branches of the Marine Industry

Over Twenty-Six Millions in Ship Work Contemplated and $12,788,820 Worth Of Contracts Placed in Seven Weeks

Developments of First Part of 1922 Indicate Remarkable "Come Back" of America's Marine Industry—Construction, Repair and Equipment Men Encouraged

BUSINESS conditions in the marine field during the first seven weeks of 1922 show a decided turn for the better if such things as the amount of prospective contracts receiving serious consideration and the amount of business placed can be accepted as a criterion. It is interesting to note that from January 1 to February 18 inclusive MARINE ENGINEERING AND SHIPPING AGE has reported over $12,788,820 in contracts placed and approximately $26,281,000 in ship construction and repair work contemplated.

Among the latest encouraging developments may be included the awarding of the *Leviathan* contract for $8,200,000, the report of two $3,000,000 ships under consideration for the Great Lakes, $4,500,000 asked for six seagoing dredges for the Government, the awarding of the contract for the construction of four steel ships in Montreal, awarding of 10,000-ton freighter at Port Arthur, Ont., two ships to be built for the Bay Line, Baltimore, Md., two ships considered for the Eastern and Clyde Line Steamship Companies jointly, ten steel oil barges for Galveston, one steel oil barge for the New York district, one vessel for Philadelphia to be used as a water boat, the prospective reconditioning of the army transport *Madawaska*, the passenger ship *Princess Matoika*, a large number of Shipping Board vessels and in addition various other repair work.

Ship charters continue fairly active, the movements of grain and sugar cargoes giving new impetus to the activity in ocean freights, and evidence of preparation for the heavy spring passenger traffic is abundant. The prevalent opinion among marine men is that "Things are looking up," and this belief is borne out by the facts.

Millions May Be Saved by New Stevedoring Rates Announced by the Shipping Board Commissioner

Further Reduction of Twenty Percent Expected to Follow Previous Cut of Fifteen Percent—Pacific Coast Situation to Be Taken Up Following South Atlantic and Gulf Ports

COMMISSIONER T. V. O'CONNOR, of the United States Shipping Board, announced on February 7 that a new schedule of stevedoring rates would go into effect at the port of Baltimore on February 10, which, it is expected will reduce stevedoring costs radically at that port. A new schedule for the port of New York was inaugurated on February 1, and a new schedule was in course of preparation for the port of Boston. This schedule will be followed by a new one at the port of Philadelphia.

Commissioner O'Connor states that after the entire stevedoring situation at northern ports has been revised, the Stevedoring Committee of the Board having this matter in hand will proceed to southern ports to revise the rates now operative there. It is expected that the Pacific Coast situation will be taken up after the South Atlanic and Gulf ports have been revised, which will complete a reduction in stevedoring costs at all ports in the United States. It is confidently predicted by Commissioner O'Connor, who is supervising stevedoring work for the Shipping Board, that several million dollars will be saved the Board by the new rate schedules already arrived at and those to be worked out in the next few months.

Some months ago stevedoring rates were reduced 15 percent owing to a reduction in the cost of labor of that amount. It is expected that the schedule of rates just put in force will work a further reduction of at least 20 percent and perhaps considerably more.

The schedule at New York has been worked out according to trades, the rates being fixed in each trade according to the peculiarities of cargo handled and the number of ports to which the lines run. A set of conditions was also worked out to control the operation of the new schedule, which conditions are uniform for the entire port of New York. Negotiations have been going on for some time.

Half Million Dollar Job on S.S. Columbia Awarded Sun Shipbuilding Company

The steamship *Columbia*, formerly the *Great Northern*, sister ship of the *Northern Pacific* which was destroyed by fire recently, has been purchased from the United States Government by the Admiral Line at a price said to be $1,250,000 and the contract for reconditioning the ship for service for the Admiral Line has been let to the Sun Shipbuilding Company, Ltd., at Chester, Pa., at a price reported as close to $500,000, according to latest advices received by MARINE ENGINEERING AND SHIPPING AGE.

It is announced that the *Columbia* has been ordered from Cuba to the Brooklyn Navy Yard where various navy equipment will be removed, the vessel then to proceed to the Sun shipyard at Chester, where a large force of workmen will begin the work of reconditioning the ship. It is understood that the work involves extensive hull and machinery repairs, the biggest item probably being the work incidental to the installation of first class accommodations for about 675 passengers.

Bids Asked for New Cable Ship to Cost About Half a Million

Plans and specifications have been completed by the firm of Cox and Stevens, naval architects, 25 Broadway, New York, for the construction of a new cable steamer, bids for which will open on or about March 1. Preliminary estimates place the cost of the ship at approximately a half a million dollars.

The vessel will be about 169 feet long, 30 feet beam, 22 feet 6 inches depth constructed of steel. She will be an oil burner driven by a triple expansion engine, 17 by 25 by 45 by 30-inch stroke. Steam will be supplied by two Scotch boilers, 12 feet in diameter, 11 feet long with a steam pressure of 185 pounds. In addition to other equipment, the vessel will have a steam-driven ice-making machine of 4 tons capacity.

Brazil Reported in Market for New Ships

Experts in the commercial life of Brazil arrived at Newport News, Va., on February 16, from Washington, D. C., on board the pilot boat *Virginia*. They were scheduled for inspection of the plant of the Newport News Shipbuilding & Dry Dock Company and it is understood their country is in the market for ships. They were given a luncheon by the shipyard at the Tidewater Club and were later banqueted by shipping and business interests.

Award of Half a Million In Shipping Board Reconditioning Contracts Is Under Way; Lone Star State Was the First of Series

Plans and Specifications Cover Chiefly the Installation of Third Class Passenger Accommodations in Preparation for Spring Rush

THE first of a series of repair contracts which will probably reach a total cost of close to half a million dollars, is expected to be awarded by the Shipping Board at 45 Broadway, New York. The contract for the reconditioning of the steamships *Lone Star State* and *Peninsula State,* the principal work to consist of extension of the third class passenger accommodations, has already been awarded to the Robins Dry Dock & Repair Company, Brooklyn, N. Y., at a price of $84,000.

It is expected that, following the *Lone Star State,* six other of the "State" ships will undergo similar reconditioning from time to time. The *Lone Star State* and *Peninsula State,* it is reported, will probably make about four trips for the United States Line, when they will be replaced permanently by the *Hawkeye State* and the *Buckeye State.* All of these vessels are "535s." The *Panhandle State, Centennial State* and the *Old North State,* which are of the "502" class, will probably also be similarly equipped.

The extension of the third class accommodations in these American passenger ships will be completed in time to meet an anticipated rush of business in ocean traffic which is expected to start early this spring.

$100,000 Job Coming on Steamship Princess Matoika

Further preparation for the spring rush of ocean passenger traffic will be made on the steamship *Princess Matoika* upon her return from her forthcoming voyage, when accommodations will be installed in the ship for approximately 1,200 third class passengers. Plans and specifications for this work are reported to be already under consideration and it is expected that the work of reconditioning the ship will reach a total close to $100,000.

The steamships *Hudson* and *Potomac* will also be added to the list of ships which are to undergo extension of third class accommodations.

SHIP OWNERS MEET

Steady Improvement in Shipping Predicted Following Federal Aid

At the annual meeting of the American Steamship Owners' Association, on February 6, at 11 Broadway, H. H. Raymond, president of the Clyde-Mallory Lines, was reelected president of the association, and Edward J. Barber, president of the Barber Steamship Lines, Inc., was reelected vice-president. The shipowners went on record unanimously in favor of the adoption of a Continuous Discharge Book of reference and recommendation for seamen, similar to a system long in effect in the British merchant service and now in effect on the Pacific coast of the United States.

Resolutions of sympathy on the death of Albert R. Lafonta, president of Harriss, Magill & Company, Inc., and of the firm of Trosdal, Plant & Lafonta, ship operators, were adopted. Winthrop L. Marvin, vice-president and general manager, and J. Parker Kirlin, Esq., general counsel, were reelected by the executive committee.

President Raymond, in closing his report of the activities of the association for the past year, referred to the year as one of world-wide depression in the shipping trade, and added that American shipowners are convinced that if the Federal Government keeps its pledge of giving the ocean shipping industry proper aid comparable with that long extended to other industries, there will from now on be a steady improvement in the status of the American merchant marine.

President Raymond further reported that the total gross tonnage of seagoing steamships owned by member companies of the association was 3,309,478, a gain of 343,400 over the preceding year.

QUICK TURN AROUND

Steamship George Washington Is on Notable Voyage

When the steamship *George Washington,* of the United States Lines, left the port of New York on February 14, she accomplished one of the quickest "turn-arounds," for a vessel of her size, in the history of the harbor.

Advices received by the United States Shipping Board Emergency Fleet Corporation, showed that the big liner, delayed by gales and fog on her voyage from Bremen, was unable to reach her pier until February 12. Immediately upon being made fast to the dock, the work of discharging her cargo and furnishing her with fuel and supplies began. The colossal task involved continuous labor both by day and night, and as a result of the superhuman effort that was made, she was enabled to sail in a little more than 48 hours, fully conditioned, with 652 passengers, on a voyage that will last to the middle of April.

The cruise of the *George Washington* gives promise of being a romantic one, for the women outnumber the men making the trip, by 200. Of the 652 passengers, 426 are females and 226 males, and of the former 155 are single girls, many of them being debutantes making their first oveaseas voyage.

During the cruise the *George Washington* will touch at Azores, Madeira, Cadiz, Gibraltar, Algiers, Palermo, Naples, Athens, Constantinople, Beirut, Naifa, Alexandria, Cerfu, Cattaro, Corsica, Villefranche and Cherbourg.

Captain Harold R. Cunningham, skipper of the *George Washington,* brought the liner from Quarantine to Hoboken and made fast, all in 70 minutes, which was considered remarkable work in view of the weather which prevailed.

New Passenger Services

The Algerian American Line, 44 Whitehall Street, New York, which was recently incorporated, announces a new steamship service to Italian, Spanish and North African ports, to be inaugurated with the sailing of the French steamer *Bay Verdun* early in March. The service will be started with three ships of 9,000 tons each, and three additional vessels of 10,000 tons each will be added later.

The American Line of the International Mercantile Marine Company, 9 Broadway, New York, has announced plans for the operation of a regular passenger steamship service from Philadelphia and Boston to Queenstown and Liverpool, beginning in March. The steamers *Pittsburgh* and *Haverford* will ply in this service.

Steamship Interests

A report from San Francisco states that a new steamship company, financed by American and Chinese capital, is negotiating with the War Department for the purchase of surplus transports, to be used in a service which they propose to establish between Pacific Coast and Chinese ports with feeder lines to the Straits Settlements.

Fred W. Eansor, head of the Southern Shipping Company, Jacksonville, Fla., has announced the inauguration by his company of a regular schooner line between Jacksonville and the West Indies. Two vessels are now in this service and more will be added as business warrants.

According to an announcement by the Shipping Board at Washington, D. C., the new passenger steamers *Nutmeg State* and *Palmetto State,* of 13,000 tons each, have been assigned to the Munson Steamship Line as managing agents for service to South America.

The United States Lines have announced the installation of a one-cabin service between New York, Queenstown, Cherbourg, Southampton and London to be inaugurated with the sailing of the *Panhandle State, Centennial State* and *Old North State,* these ships to be shortly augmented by two others. The conversion of these "State" vessels for the new service involves merely the addition of two berths above the present hotel beds, thus giving accommodations for four persons instead of two. The changes in the three boats will be started immediately and the new schedule will be in full operation in time for the spring rush.

According to an announcement from Boston, Mass., the United Fruit Company has made a reduction of about 20 percent on grain rates to Jamaica and the east coast of Colombia. Rates on rice have also been reduced.

The Robert Dollar Company has purchased four steel freighters of 10,200 deadweight tons each, at a price of $300,000 or less than $30 per deadweight ton. They are the *Cathay, Celestial, Oriental* and *Mandarin* which were built for the Shipping Board by the Kiangnan Dock & Engineering Company's yard at Hongkong, China, at a cost of about $200 a deadweight ton. They will be used by the Dollar Company in their coastwise trade.

Sixty More Ships May Be Put Into Service

Newport News, Va. (Special).—United States Shipping Board officials here, having been advised that headquarters in Washington expect to see the sugar business from Cuba to America take a big jump shortly are planning to get perhaps as many as 60 of the "lake" type of steel vessels down from Camp Eustis' idle fleet for repairs.

Two Palatial Ships Planned For Lake Service; Wilmington Firm Will Build Two for Seaboard-Bay Line

Four and a Half Millions May Be Spent for Sea Dredges—Newest Developments Give Powerful Impetus to Forward Movement of American Marine Industry

SIX MILLION DOLLARS for the construction of two new passenger ships for Great Lakes service, a request for an appropriation of $4,500,000 for the building of six seagoing dredges for the Government, and the awarding of a contract for two passenger and freight steamers for service between Baltimore, Md., and Old Point Comfort and Norfolk, Va., at a total cost of approximately $2,000,000—these are the "high spots" in the latest developments in American marine activities.

The two newest additions under consideration for the Great Lakes fleet, originally reported by Marine Engineering and Shipping Age on July 30, 1921, will be of the most palatial type, about 600 feet in length, for the Cleveland & Buffalo Transportation Company, Buffalo, N. Y. Complete details as to propulsion, machinery, or other equipment for these vessels are not yet available as it is understood that plans and specifications have not yet been completed. With regard to the two steamers for the Seaboard-Bay Line, which were forecasted in our weekly issue of January 28, the contract has been awarded to the Pusey & Jones Company, Wilmington, Del. It is believed that these vessels will cost close to a total of $2,000,000.

These vessels will be built of steel, 330 feet long, 58 feet beam, 18.6 feet deep and of 2,750 gross tons. The steel shell will have flared out guards, thus dispensing with the usual overhung deck supported by brackets or braces. Propulsion will be by a 4-cylinder triple expansion vertical inverted steam engine driving a single bronze propeller. Steam will be supplied by four single ended cylindrical return tube Scotch boilers using coal as fuel although it is probable that provision will be made also for the storage and burning of oil for fuel.

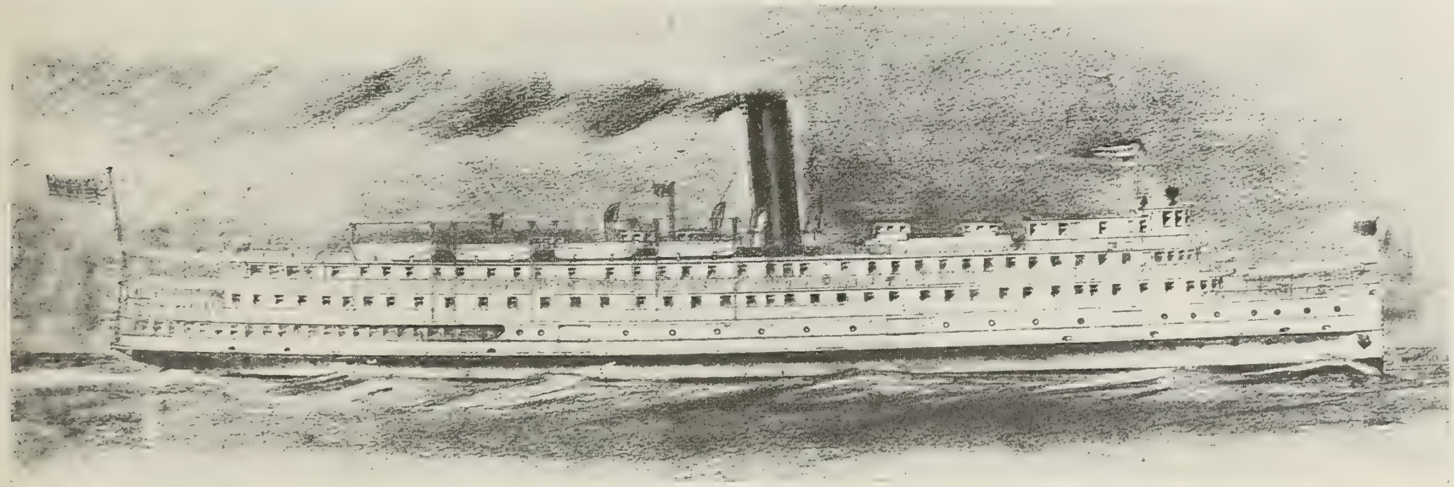
There will be 175 staterooms all heated by steam and provided with sanitary metal beds, and other incidental stateroom equipment. Special bedrooms are arranged ensuite with private bathrooms while others have showers and Pullman accommodations.

Ample space will be provided on the lower deck forward for carrying perishable cargo in cold storage and a large refrigerating plant will be installed.

The vessels will be subdivided by watertight bulkheads and equipped with fire fighting and life saving apparatus, required by the latest rules of the United States Steamboat Inspection Service for the safety of passengers and the vessels. Various other modern features will be provided to give the steamers the maximum of efficiency, safety and comfort.

The request for $4,500,000 for the construction of six seagoing dredges, fully equipped, is reported from Washington to be already "In committee" and action is looked for in the near future.

According to the latest design of dredge for use by the United States Engineer Department on bar dredging, the general specification provides for a length overall of 247 feet 3 inches with a beam, molded, of 46 feet, the boats to have four hoppers with a total capacity of 1,250 cubic yards. The vessels will be equipped with two triple expansion engines, 15 by 26 by 44 by 26.



Official Sketch Showing Type of Steamer to Be Constructed by Pusey & Jones for Seaboard-Bay Line

Five Million In New Special Type Ocean and Lake Freighters Considered For Construction In Eastern Yard

Central Steamship and Commerce Corporation Contemplates Building Fifteen 257-Foot Diesel Electric Cargo Boats to Run Between New York, West Indies and Great Lakes

THE construction of fifteen ships, having an estimated cost of close to $5,000,000, is contemplated by the Central Steamship & Commerce Corporation, 30 Broad Street, New York City, according to official information obtained by Marine Engineering and Shipping Age. Plans and specifications for these vessels, which are to be Diesel electric boats for service through the Welland Canal and the New York Barge Canal between New York and Chicago and also to the West Indies when canal traffic is closed, are being prepared by Theodore D. Wells, naval architect and marine engineer, 11 Broadway, New York.

Preliminary plans provide for the construction of a special type of ship, built of steel, 257 feet over all length, 42 feet beam, 18 feet deep and equipped with Diesel engines developing 1,300 horsepower. There will probably be two generating sets and one motor and all auxiliaries on the vessels will be operated by electricity. There will be two refrigerating holds with refrigerating machinery of about 70 horsepower. The ship will develop a speed of about 10 knots loaded. Each vessel will be equipped with two cargo masts forward and two aft.

Contract Is Placed for New Steel Coal Carriers

Contract for the construction of four steel cargo ships has been awarded to Fraser Brace & Company, Ltd., Montreal, Can., with which the New York Harbor Dry Dock Company is connected, the work to be done at Trois Rivieres P. Q. The ships are to be coastwise coal freighters for the George Hall Coal Company of Montreal.

The vessels will be 250 feet in length between perpendiculars, 43 feet molded beam, and 20 feet 6 inches deep, built partly on the Isherwood plan. They will be 2,450 net tons and will be propelled by triple expansion reciprocating engines of 1,400 indicated horsepower. Steam will be supplied to the vessels by 2 single ended Scotch boilers carrying about 200 pounds pressure. They will be coal burners.

Each ship will be equipped with electric lighting plant and a refrigeration system of a type not yet decided upon, and deliveries will start in June.

Marine Construction News of the Month

Ship Contracts — New Ship Concerns and Shipyard Improvements—Terminal Projects—Government Contracts

SHIPS AND SHIPBUILDING

To be Oil Burner, Boston, Mass.—United Fruit Company steamer Carrillo has been withdrawn from Boston service in order to be converted into oil burner.

New Lake Passenger Ships, Buffalo, N. Y.—Cleveland & Buffalo Transportation Company is considering construction of two palatial passenger ships for Great Lakes service, to be about 600 feet in length.

Ship Contract Award, Wilmington, Del.—Contract for construction of two 330-foot freight and passenger vessels for Seaboard-Bay Line awarded to Pusey & Jones; to cost about $2,000,000.

Sea Dredges, Washington, D. C.—Request for $4,500,000 for construction of six seagoing dredges fully equipped is now "in committee" at Washington and action upon it is expected shortly.

Oil Barge, New York.—Army Engineers Office, 39 Whitehall street, will open bids about March 15 for construction of steel oil barge with necessary equipment for use as supply boat in harbor to Government oil burning drill boat already under contract. Length, 85 feet, 2,200 barrels capacity; about $25,000.

Ships to Be Refitted.—Plans are now being drawn for refitting, with additional oil tanks and refrigeration facilities, the 535-foot Shipping Board steamers American Legion and Southern Cross, operated by the Munson Line.

Reconditioning Contract, Oakland, Cal.—Oliver Olson let contract for steamer Ghislaine to Moore Shipyards for engine repairs, $8,750, and Hanlon Dry Docks for hull repairs and painting, about $22,000.

Steamer Reconditioning, Baltimore, Md.—American-Hawaiian Line steamer Pennsylvanian undergoing extensive repairs at Bethlehem plant.

To Electrify Dredges, Portland, Ore.—Plans and specifications are being prepared for the electrification of one or more dredges operated by Port of Portland. James Polhemus, port manager.

Ship Conversion, San Francisco, Cal.—A. DeYoung was low bidder for conversion of the West Lewark from a freighter into army transport to replace Army transport Dix. Work includes tearing out of large part of inside construction, installation of bunks and stalls for horses and mules; $65,617.

Collision Repairs, Philadelphia, Pa.—Wm. Cramp & Sons Ship & Engine Building Company was low bidder for repairs to steamer Danholm at a price of $3,990 and five days.

Reconditioning Contract, Brooklyn, N. Y.—Robins Dry Dock & Repair Company was awarded contract for Shipping Board steamers Lone Star State and Peninsula State; $84,000.

New Liner for Lakes, Port Arthur, Ont.—Canadian Pacific Railway Company reported to be negotiating with Port Arthur Shipbuilding Company for construction of large lake passenger ship.

Diesel Engines, Auburn, N. Y.—The McIntosh & Seymour Corporation has been awarded contract for ten 150 brake horsepower Diesel engines for installation in new packets designed by R. R. Livingston, for Canal & River Transportation Company, New York.

Liner Overhauling, Seattle, Wash.—Steamer Admiral Watson, of Admiral Line, plying in Seattle-Alaska trade will be laid up for a month to undergo annual overhauling and inspection.

Schooners, San Francisco, Cal.—Three schooners purchased in France by Oliver Olson are en route to San Francisco to undergo reconditioning for lumber trade.

Contract Award, Newport News, Va.—The Newport News Shipbuilding & Dry Dock Company received contract for extensive reconditioning of steamship Leviathan to cost $6,110,000. Together with other items total cost will be $8,200,000.

New Lighter, Cleveland, Ohio.—Plans for modern lighter to replace the Newman, recently wrecked, will be started immediately by Great Lakes Towing Company.

May Convert Steamer, Portland, Maine.—Wooden steamer Bassan, built and equipped for Emergency Fleet Corporation during war at price of $700,000 and recently sold at sheriff's sale for debt of $6,000, has been purchased by R. W. Page, Skowhegan, Me., who considers repairing and recommissioning her as steamer with alternative plan of converting her into five-masted schooner.

Large Repair Jobs, San Francisco, Cal.—Moore Shipbuilding Company, Oakland, awarded contract for reconditioning Pacific Mail liner Empire State, including changes in officers' and crew's quarters, ventilation system, installation of new feed fuel pipe and other work, all amounting to $38,000. Steamer Supply awarded to Crowley Shipyards for boiler and engine repairs, etc.; price $38,000.

Cargo Ships, Three Rivers, P. Q.—Fraser-Brace & Company, Ltd., Montreal, Can., received contract for construction of four steel cargo ships to be used in coastwise coal trade of George Hall Coal Company, Montreal. Dimensions, 250 feet length between perpendiculars, breadth, 43 feet molded, and 20 feet 6 inches deep, built partly on Isherwood plan, and of 2,450 tons net.

Additional Accommodations for Liners, New York.—Plans and specifications are under consideration for addition of 1,200 third class passenger accommodations on steamer Princess Matoika, to cost about $100,000. Steamers Hudson and Potomac also listed for similar additions.

Steamer Repairs, San Pedro, Cal.—Steamship Harvard drydocked at Los Angeles Shipbuilding Company plant for repairs to frame and general overhauling; price $38,500.

General Repairs, Newport News, Va.—Shipping Board officials are planning to get perhaps sixty of "lake" type vessels down from Camp Eustis' idle fleet for general repairs prior to being placed in Cuban sugar trade.

Towboats, Rondout, N. Y.—Hildebrant Dry Dock Corporation has contract for construction of three 70-foot wood towboats, propelled by 240-horsepower Diesel engines furnished by New London Ship & Engine Company.

Will Recondition Steamers, New York.—Ward Line plans reconditioning of steamers Orizaba and Siboney now plying in Cuban service.

New Passenger Steamer, San Francisco, Cal.—Inter-Island Steam Navigation Company, Honolulu, T. H., called for bids for 360-foot express passenger steamer of 16½ knots.

New Cable Ship, New York.—Plans and specifications have been completed by Cox & Stevens, 25 Broadway, for construction of cable steamer, bids for which will open on or about March 1. Ship will be about 169 feet in length and cost approximately half a million dollars.

Shipping Board Repair Work.—The Shipping Board is taking out of "lay-up" at least ten steamers to be repaired and made ready for call. Cost about $50,000. Steamship Susquehanna to be reconditioned, about $15,000.

Tug Repairs, Brooklyn, N. Y.—Clinton Dry Docks, Inc., were awarded contract for reconditioning United States Shipping Board ocean-going tug Butterfield at price of $13,900.

To Repair Dredge, New York.—Standard Shipbuilding Corporation, Shooters Island, N. Y., was low bidder for job of reconditioning Government seagoing dredge Atlantic at price of $18,500.

Boat Contract, Collingswood, Ont.—Collingswood Shipbuilding Company received contract from T. Dick, Jr., president of National Sand & Material Company, for construction of sand and gravel carrier of 2,000 cubic yards capacity.

Repair Contract, Brooklyn, N. Y.—Old North State awarded by the Shipping Board to the Morse Dry Dock & Repair Company for repairs amounting to $24,950.

Fireboat to be Equipped, Norfolk, Va.—City plans outfitting fireboat Quaker No. 2 to make her efficient as a fire fighter. Boat is in good order and only requires a few changes in her mechanism for installation of equipment. Fire underwriters urge that work be done immediately.

To Buy Steamers, San Francisco, Cal.—S. A. Perkins, president of Alaska Transportation Company, a new firm, is reported to have come from Tacoma for the purpose of negotiating for purchase of three steamers for the passenger and freight service which the company will engage in to Alaska.

May Purchase Vessel, Hampton Roads, Va.—Representatives of A. H. Bull & Company were here recently inspecting laid-up ships of "Lake" type with view of purchasing one from the Shipping Board.

PORT IMPROVEMENTS

Large Terminal, Beaumont, Tex.—Santa Fe Railroad system is reported as planning to establish its own terminal on Beaumont waterfront in order to facilitate rapidly increasing tonnage handled. Several sites on Neches River are also being considered. Project will cost approximately $1,000,000.

Pier Extension, San Francisco, Cal.—Work will soon be started on extension of Pier 22, occupied by Charles Nelson Company. Three hundred feet of pier space will be added at estimated cost of $140,000. Harbor board also contemplates lengthening Pier 34.

Docks, Etc., Cape May, N. J.—Progressive League selected site at Cape May Point Boulevard for erection of docks and a ferry house to be used by New Jersey-Delaware ferry.

Terminal Expansion, Wilmington, N. C.—Standard Oil Company reported to be planning doubling capacity of its terminals.

Canal, Etc., Port Arthur, Tex.—G. N. Bliss, chairman of Chamber of Commerce, reports project of deepening canal from gulf to Beaumont to depth of 30 feet in canal and 32 feet over bar with bottom width of 125 feet in Sabine-Neches canal, and 300 feet at jetty; about $1,795,000.

Pier Extension, Tacoma, Wash.—Plans are now under consideration by Port Commission to equip harbor with largest exclusive lumber pier in United States. Present pier will be extended 400 feet, giving structure total length of 1,200 feet; about $90,000.

Terminals, Portsmouth, Va.—City Manager Jervey plans construction of municipal terminals.

Sea Wall, Cocoa, Fla.—City contemplates construction of sea wall entire length of water front. Address the mayor.

Dredging, Baltimore, Md.—City plans dredging 800-foot channel at foot of Eutaw and Alluvian streets, Spring Gardens, 75 feet wide and 17 feet deep. About 20,000 cubic yards of material will be excavated; about $100,000. B. Hill, harbor engineer.

Ferry Slips, San Francisco, Cal.—Golden Gate Ferry Company preparing plans for construction of ferry slips in Sausalito and on State property on San Francisco waterfront for use of its automobile ferry line.

Ferry Terminals, Oakland Cal.—Six Minute Ferry Company plans construction of terminals at Oakland and San Francisco for automobile ferry line.

Pier, Philadelphia, Pa.—Philadelphia, Baltimore & Washington Railroad Company plans construction of pier and four pile clusters inside bulkhead line in front of their property on west bank of Schuylkill River; about $10,000.

Ferry Terminals, Haverstraw, N. Y.—A new ferry service will soon be inaugurated by E. N. Goodhall, of Alburgh, Vt., head of Lake Champlain Ferry Company, between Haverstraw and point on Hudson River directly opposite. Company plans construction of bulkhead and slips and dredging terminals to sufficient depth to permit docking of ferryboats.

Jetty, Longport, N. J.—Construction of stone jetty planned at entrance to Coldspring Inlet and Cap May harbor; about $100,000.

Pier Equipment, Etc., Tampa, Fla.—$1,000,000 bonds issued to cover cost of contemplated port improvements, including pier 870 feet long with shed and equipped with modern cargo handling machinery. A. W. D. Hall, city engineer.

Jetties, Dredging, Etc., Fort Lauderdale, Fla.—Broward County Commissioners plan extensive harbor improvements, to include cutting of the bar opposite mouth of New River, building jetties, and dredging basin in New River Sound; $100,000 bond issue.

Wharves, Houston, Texas.—City let contract to Charles K. Horton to build additions to cotton wharves on north side turning basin; building a shed 100 by 800 feet, and laying track between widened platforms; price, $107,450. J. C. McVea, city engineer.

River Terminal, Louisville, Ky.—Construction of river terminal contemplated. Huston Quinn, mayor.

Docks, Mobile, Ala.—City will soon vote on bonds for construction of docks and other terminal improvements. Address the mayor.

River Landing, Vicksburg, Miss.—City will vote May 9 on $80,000 bonds for construction of river landing. Address the mayor.

Improve Harbor, Richmond, Cal.—United States Government will soon let contract for construction of retaining wall and dredging of harbor.

To Remodel Docks, Houston, Texas.—City plans remodeling of cotton docks to cost about $115,000. J. C. McVea, city engineer.

Wharf, Etc., Petersburg, Fla.—City contemplates deepening Bayboro harbor to 18 feet and building 600-foot wharf. Bond issue, $100,000. Address the mayor.

Seawall, St. Augustine, Fla.—City Commissioners have prepared tentative plans for extension of seawall out to deep water mark.

GOVERNMENT WORK

Dredging, Key West, Fla.—United States Engineer Office, Jacksonville, will receive sealed proposals until 12 M., March 14, for dredging in Key West harbor. Further information on application.

Dredging, Nashville, Tenn.—War Department, Lieutenant-Colonel J. R. Slattery, Box 900, will dredge between municipal terminal and channel proper at Cumberland River; about $15,000.

Harbor Survey, Charleston, S. C.—War Department making surveys in Town Creek and over Cooper River between Navy Yard and Army Base, as part of general plans for future work in improving harbor. Major G. R. Young, U. S. A., engineer.

Dredging, East Boston, Mass.—Specification 4552. Bureau of Yards and Docks, Navy Department, Washington, D. C., awarded contract to Bay State Dredging & Construction Company, 62 Condor street, for dredging Goat Island at price of 72 cents per cubic yard, scow measure in place, or total of $8,500.

Specifications, Washington, D. C.—Following specifications are available at or in contemplation by Bureau of Yards and Docks, Navy Department, Washington, D. C., for various work or material as follows: Ordnance Station, Puget Sound, Wash., addition planned to building 368, specification 4577; heating system, Sayville, N. Y., planned in radio station, specification 4578; gun shed and stable, San Diego, Cal., construction planned for Marine Corps Base, specification 4579.

Pumping Unit, Chesapeake City, Md.—United States Engineer Office, Wilmington, Del., will receive sealed proposals until 11 a. m., March 20, for furnishing and installing one complete pumping unit, consisting of centrifugal pump directly connected to engine, etc. Further information on application.

NEW INCORPORATIONS

The Progressive Steamship Company has been incorporated with a capital of $200,000, at Dover, Del. Charles T. Magee and Ward C. Henry, of Philadelphia, and Henry D. Smith, of Atlantic City, are among the incorporators.

The Piermont Navigation Company, New York, has been incorporated by Theo. L. Ernst, S. E. Freeland and Samuel Baras, all of New York. The American Guaranty & Trust Company is agent.

The Atlantic Mail Corporation, Manhattan, has been incorporated with a capital of $500,000 to engage in commerce and navigation. E. N. Abbey is incorporator.

The China America Steamship Corporation, Manhattan, has been incorporated by F. Kiers, 540A Henry street, Brooklyn, N. Y., with a capital of $150,000, to engage in commerce and navigation.

The Quebec Shipbuilding & Repairing Company, Ltd., Quebec, Can., has been incorporated under the Dominion Companies Act, with a capital of $500,000, to carry on a general shipbuilding, repairing, chartering and navigating business; to own and operate ships, dry docks, shipyards, etc.

The Republic Navigation and Transportation Corporation, Wilmington, Del., has been incorporated with a capital of $1,750,000, to build, own and operate boats.

The Asiatic American Steamship Company has been incorporated at Portland, Oregon, with a capital of $100,000, to own and operate boats.

FOREIGN ACTIVITIES

Quay Extension, Ghent, Antwerp.—Projected improvements at the port will increase Scheldt quay to 10,000 meters. A 70-ton floating crane is contemplated.

Naval Construction Program, Spain.—Council of ministers approved naval construction plans for modernizing all type of war vessels, increasing tonnage of torpedo boats and building scout cruisers of 8,000 tons each.

Shipbuilding, Norway.—Norway is developing its shipbuilding resources and now has eight sizable shipyards. The Rosenberg Mek Verksted at Stavanger is making pretentious additions.

Harbor Improvements, Denmark.—Copenhagen Government introduced into Danish Folketing proposal to grant 4,564,000 kroner for extension and improvement of Slesvig harbors at Hardersley, Aabenraa, and Sonderburg.

Intermediate Type Ships, Italy.—It is anticipated that Bellotti scheme for building intermediate type vessels for use on certain agreed lines in Italy under Government subsidy will become law. This should provide employment for Italian shipyards during coming year and serve to stem heavy increase in number of unemployed.

New Shipbuilding Company, Austria.—Austrian Shipyards Company, formed with purpose of rebuilding Austrian mercantile marine, has been registered at Vienna under auspices of Kredit Anstalt and Hamburg American Line. Majority of shares to be in Austrian hands, with Hamburg American interested to extent of 10,000,000 crowns.

Diesel Engines, England.—Vickers, Ltd., Barrow-in-Furness, are reported to have received orders to construct Diesel engines for minelayer to be built in one of Government dockyards.

Barge, England.—Contract for construction of self-propelled barge was awarded to Vickers, Ltd., Barrow-in-Furness, by Furness Railway Company.

New Freight and Passenger Steamers, England.—Cammel-Laird & Company, Ltd., Birkenhead, has order from Alfred Holt & Company for construction of 11,000-ton freight and passenger vessel to be a twin-screw and gear driven. The Holt Company also awarded contract to Scott's Shipbuilding & Engineering Company for a twin-screw steamer, 400 feet in length.

Launchings, Etc., England.—Harland & Wolff during year 1921 are reported as having launched eight vessels of 69,753 gross tons, and completed propelling machinery representing 59,600 indicated horsepower.

England-Australia Service. — Commonwealth Government Line has inaugurated fast steamship service out of London to Australia. Five new steamers of uniform design and speed and of 14,000 tons each will ply in this service.

Cargo Vessels, Germany.—Danziger Werft, according to report, has secured large foreign orders requiring employment of 1,200 additional workmen. Among orders are two 2,000 ton cargo vessels for Chilian Government to be ready in six months. It is proposed to convert the concern into company with the participation of international capital.

Capital Increase, Germany.—North German Lloyd, at meeting in Berlin, increased its capital to 600,000,000 marks, an increase of 125,000,000.

Shipbuilding Output, Germany.—Lloyd's Register reports the launching in German shipyards of 509,064 gross tons, or 42,000 tons more than the gain for all other countries than America and Great Britain, so that the minor nations, excluding Germany, showed an actual loss on the year's output. German returns show that the shipyards of Germany have now more than regained their pre-war production as their previous record year for launchings was in 1913 when tonnage launched aggregated 465,000 gross tons.

Steamers Remodeling, Germany.—The steamers Resolute and Reliance recently acquired by the United American Lines will be extensively remodeled at Hamburg. Passenger accommodations will be cut in half to add conveniences for second and third class passengers. Thirty additional second cabin rooms will be added.

New Shipping Company, Germany.—The Deutsch-Skandinavishe Reederei, A. G., a new shipping company, has been organized at Hamburg, with a capital of 7,000,000 marks to carry on trade between Germany and Scandinavia.

Diesel Engines, Japan.—Japanese Government recently placed order with Sulzer Brothers for Diesel engines to be installed in new submarines. The engines are to be 4,000 horsepower, and each vessel will be equipped with engines aggregating from 16,000 to 20,000 horsepower; about £1,250,000.

New Vessel, China.—Ningpo-Shoashing Steamship Navigation Company has announced capital increase of $500,000, which will be used for construction of large vessel for the Yangtze service.

Steam Launches, China.—It is reported that Yuan Chaoching, of Tzo-chuen, Shantung, plans construction of four steam launches to establish service along Sing-Ching-Ho from Wang-tan-jao to Yang-kao-kiu by way of Wu-ho.

Harbor Development, Japan.—The municipal authorities of Tokyo are reported to have decided to construct a harbor at an estimated cost of Y.350,000,000.

New Shipyard, Japan.—The Kawasaki Dock Company plans construction of a shipyard near Kokura. Capacity of the new dockyard contemplated will be so large that a merchant or war vessel of any size now afloat will be accommodated.

Motorship Construction, Germany.—The Deutsche Werft, Hamburg, has received from a firm in Christiania, Norway, contract for construction of three motorships of from 8,000 to 9,000 tons each. They are of special design and will be used to carry frozen meat from Australia to Argentine.

Large Harbor Project, Italy.—John R. MacArthur, of MacArthur Brothers, New York, has signed a contract with the Italian Government for extensive improvement of Palermo harbor, Sicily, including dredging, construction of sea walls and moles. An Italian company will be formed to undertake the work, which will require about ten years. American machinery will be imported.

New Steamer, China—The Ping An Dockyard, Shanghai, is building a steel vessel, the Singpaohua, which will be ready for launching this spring. When completed, vessel will be placed in service between Shanghai, Chow-shan, Haimen and Shih-poo.

New Shipping Enteprises, Germany—A new shipping organization to be known as Deutsch-Skandinavische Reederei A.G., with a capital of 7,000,000 marks, has been formed at Hamburg to carry on trade between Germany and Scandinavia. At Geestemunde another shipping enterprise, the Ubersee Reederei, has been formed with a capital of 7,500,000 marks.

Bill for Conversion of 112 Ships Into Motor Vessels Is Before Congress

Honorable Harry C. Gahn, of Cleveland, Ohio, introduced a bill in the House of Representatives, on February 21, 1922, to authorize and direct the Secretary of the Treasury of the United States to issue legal tender money to purchase from and pay therefor the United States Shipping Board Emergency Fleet Corporation for 112 Submarine Boat Corporation type vessels of about 5,375 deadweight tons each, totaling about 602,000 deadweight tons, and contract for converting such vessels into motorships in order to assist in providing and expanding an American merchant marine.

Sun Shipbuilding Company Is Low Bidder for New Steamer

Of the fifteen companies submitting tenders, the Sun Shipbuilding Company of Chester, Pa., with a price of $1,027,000, was low bidder for the construction of a 360-foot express passenger steamer for the Inter-Island Steam Navigation Company, Honolulu, T. H. The Newport News Shipbuilding & Dry Dock Company was second lowest with a bid of $1,100,000. The vessel will be used in the company's inter-island trade and will have a speed of 16½ knots.

BUSINESS NOTES

The United States Navigation Company, general agents of the Reardon Smith Line, Ltd., in New York, has moved its offices from 66 Broadway to the Whitehall Building, 17 Battery Place.

The Boston office of the Cutler-Hammer Manufacturing Company, Milwaukee, Wis., has been moved from the Columbian Life Building, to rooms 403 and 404 Harvey Building, Chancy St., with Mr. C. W. Yerger as manager.

The Wilson Welder & Metals Company has moved its general offices and Bush Terminal factory to 132 King Street, New York City.

The Philadelphia office of the Hauck Manufacturing Company, manufacturers of portable oil burners, torches, furnaces, etc., has been moved to 1726 Sansom Street. Mr. Herbert Vogelsang will be in charge.

H. B. Price, formerly advertising manager of the Belden Manufacturing Company, Chicago, has joined the advertising agency of George J. Kirkgasser & Company. Mr. Price will specialize in electrical and technical advertising and in addition to an engineering education brings to his new work a wide practical experience in engineering, construction, sales and operation.

The Pneumercator Company, Inc., announces the removal of its general offices from 15 Park Row, New York City, to 40 Flatbush Avenue Extension, Brooklyn N. Y.

The firm of Cox & Stevens, naval architects, ship surveyors and brokers, will move on March 1 to their new offices in the Cunard Building, 25 Broadway, New York. Their new quarters are directly accessible from the Morris Street entrance and will be sufficiently large to accommodate, in addition to the executive staff, their designing force which for several years past was located in Brooklyn.

TRADE PUBLICATIONS

Iron Workers Tools.—The Scully Steel and Iron Company, Chicago, is sending out a somewhat elaborate pamphlet showing iron workers' tools for hand and pneumatic work. The tools are made especially for boiler makers and iron workers and include hammers, sledges, chisels, punches, rivet snaps, side sets, calking tools, drift pins, rippers, beading tools and the like. This pamphlet will be sent to any one upon request.

Sprague Electric Dynamometers.—The Sprague Electric Works, New York, has published a well illustrated circular describing the construction, control and application of the research type of the Sprague electric dynamometer which is a highly accurate and easily operable apparatus for the measure of torque or power.

New Quigley Pulverized Fuel Bulletin.—A new bulletin on the Quigley Fuel Systems, comprising methods of preparing, transporting and burning of pulverized fuels has just been published by the Hardinge Company, 120 Broadway, New York. This bulletin is known as No. 12 and treats the subject of pulverized fuels in a manner never before attempted. One of its distinguishing features is the fact that emphasis is laid upon the methods employed to properly prepare and burn the powdered coal, rather than occupying most of the space discussing the pulverizer. Aside from complete plant layouts, what the manufacturers term as a "Unit Milling Plant" is described. This layout is radically different from anything ever before developed. The System comprises a method of pulverizing and transporting the coal to one or more furnaces in the same locality, at the same time securing positive regulation and continuous operation over extended periods. The cost of this unit is but a fraction of that of the larger Systems where the coal must be transported several hundred feet to a number of furnaces. The range of capacity for the complete pulverized fuel plants is extreme.

Auxiliary Motor Control Equipment.—A bulletin containing data pertaining to marine motors and controllers for engine room auxiliaries and deck machinery on merchant ships is being distributed by the General Electric Company, Schenectady, N. Y. to assist marine engineers in their work. Concise information is given relative to horsepower, voltage, speed, weights, and approximate dimensions of standard type marine motors.

Deschanel Cableways.—A bulletin on cableway methods of handling coal and similar materials from barge or railroad car direct to storage piles or to the power house has been sent out by the Deschanel Engineering Corporation, 90 West Street, New York. Ashes can be removed from a plant by the same equipment, which consists essentially of a two-drum reversible hoist, a clam-shell type cableway bucket, and a cableway and supporting towers. Diagrams and photographs showing typical installations are given.

Boiler Tube Production.—The processes of manufacturing seamless and lap welded steel boiler tubes employed by the National Tube Company, Pittsburgh, Pa., are described in a bulletin recently issued by the company. The physical properties of these tubes are given as well as the tests and inspections necessary for their acceptance. A series of tables containing data valuable to tube users is included in the bulletin, which is of considerable interest.

MARINE SOCIETIES

AMERICA

American Society of Naval Engineers

Navy Department, Washington, D. C.
President—Capt. A. J. Hepburn, U. S. N.
Secretary-Treasurer—Commander J. S. Evans, U. S. N., Bureau of Engineering, Navy Department, Washington, D. C.

WE GUARANTEE that of this issue, 5,350 copies were printed; that of these copies, 4,059 were mailed to regular paid subscribers, 337 were provided for counter and news company sales, 212 were mailed to advertisers, 27 were mailed to employees and correspondents, and 715 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 21,800—an average of 5,450.

MARINE ENGINEERING AND SHIPPING AGE is a member of the Associated Business Papers, Inc. (A. B. P.), National Association of Periodical Publishers, Inc., New York Business Publishers' Asscciation and the Audit Bureau of Circulation (A. B. C.).

Requests for change of address should reach us two weeks before the date of the issue with which it is to go into effect. It is difficult, and often impossible, to supply back numbers to replace those undelivered through failure to send advance notice. In sending us change of address, please be sure to send us your old address as well as the new one.

The President's Plan

It is now a full month since the President submitted his well balanced plan for establishing our merchant marine.

He is to be congratulated on the fact that, although this plan contains many forms of indirect aid as well as a subsidy, no one has been able to suggest any better way to develop our shipping. Few if any cases of proposed legislation have been so admirably framed to disarm criticism and few cases are on record where the necessary legislative steps have proceeded so rapidly to carry out a President's recommendations.

The reason for this lies in the provisions that are made in the plan to benefit the exporter and importer, as well as the shipowner, to encourage the construction of ships as well as their operation, and to build up a naval reserve, thus insuring an efficient support for our warships as well as a highly trained better paid class of seamen. In fact, the President's message is more than a plan, *it is the greatest "selling" argument for an American merchant marine that has ever been presented to the American people.*

It is a selling argument to the shipper, the manufacturer or the producer, whether he exports or imports finished or raw materials, for it is plain even "to the man on the street" that whosoever routes his traffic under this plan in American bottoms may make a straight deduction of 5 percent of the freight money that he pays from his income tax.

It is a selling argument to the shipowner and the prospective shipowner for it guarantees him, in the direct subsidy, the same kind of protection against cheap foreign labor that has built up our other industries. Strange as it may seem, the shipowner, or the prospective shipowner, is the most important man to be convinced that the merchant marine can be made a profitable business for otherwise *he will neither buy nor build the ships* that are needed to adequately represent us on the Seven Seas.

It is a selling argument to the shipbuilder for it provides for a large construction loan fund at a cheap rate of interest, making it possible for responsible parties to borrow the money to construct the most modern and efficient vessels of the types that we lack, such as fast passenger and mail liners, motorships and refrigerator ships. It provides exemptions from taxes, if the money is spent in new construction in American yards. But most of all it specifies that except in very special cases no benefits under this plan will go to vessels other than *those built in our own shipyards.*

It is a selling argument to good American seamen for it assures them an American standard of wages through the creation of a naval reserve. Their uniform will bring them a certain glory and a certain respect that only those who stand ever ready to serve their country in time of need can ever expect. It is due more to this practice of England than anything else that has caused *her best type of citizens to follow the sea.*

It is a selling argument to all patriotic Americans for they cannot have forgotten how the cry went out "for ships and more ships" when the deadly submarines were at their nefarious work. They know right down in the bottom of their hearts that an adequate naval reserve of merchant ships is absolutely necessary for *the very safety of their country.*

It is a selling argument to the taxpayer for it provides a close check on the profits of the shipowner and for the return to the Treasury of excess earnings. Not only this, it provides an opportunity for the Government to sell its ships which

can be nothing else than a heavy drain on the Treasury as long as they remain idle. In fact, under this plan the *Government should take in more money from the sale of its ships than it pays out* in subsidies for some years to come.

The President has done his part, Congress will no doubt follow suit but the great mass of people do not read a presidential message as closely as they should. The Shipping Board and the shipowners who know how much benefit the whole country will receive from a merchant marine should get together and devise some means of spreading the gospel of shipping throughout the nation.

The Cost of Supporting Foreign Shipping

COMMISSIONER George E. Chamberlain of the Shipping Board gave some very interesting figures in a recent speech before the National Merchant Marine Association on the amount of money that foreign shipping interests had taken out of this country. Perhaps if the newspapers which have repeatedly suggested in their editorials that if foreign ships could carry our cargoes cheaper than American vessels it would be good business to let them do so, and that it would, in fact, help those countries to pay up their debts, were aware of the stupendous sums that we have paid for transportation, they would not let insidious foreign propaganda bias their judgment again.

Commissioner Chamberlain's figures, obtained from the Department of Commerce, show that during the six years ending December 31, 1920, the total value of our exports and imports was $47,626,671,810, and of this amount $12,129,630,431, or 26 percent of the total, was carried in American vessels. Foreign ships, on the other hand, carried commerce valued at $35,497,041,379, or about 74 percent, and of this amount, Great Britain carried $19,811,387,710, or about 42 percent of the total commerce. Taking 25 percent of the total value of the commerce as a conservative estimate of the cost of freight, banking, insurance, etc., paid out for foreign services, the money actually going out of this country to enrich foreign shipping interests in the last six years amounted to $8,874,260,345.

Although it is difficult for us to appreciate the immensity of the vast sums that must be paid out for transportation of our commerce, it requires no stretch of the imagination to note that the $8,874,260,345 paid to foreign shipping in the last six years would come pretty near to cancelling the total allied war debt to us and that in the event that we fail to properly develop our merchant marine a much smaller sum than this expended on foreign shipping every six years would more than pay our entire national debt in far less time than America, rich as she is, can possibly hope to liquidate it.

Those who advocate allowing foreign ships to handle our commerce, providing they can do it cheaper, and who think that the amount of money involved is of no relative importance would get a truer perspective of the necessity for an American merchant marine, if they would compare the total savings deposits of approximately $6,000,000,000 which represents the lifetime accumulations of our working people with the nearly $9,000,000,000 expended on foreign ships in six years.

If this is not enough to impress any fair minded American with the vastness of the sums that a merchant marine of our own would retain in this country, let him stop to consider the fact that the total amount of cash expended by the Federal Government to date on the improvement of its rivers, harbors, canals, including the Panama Canal and its fortifications, is only $1,515,931,141.33—a sum which foreign ships would carry away in three or four years of normal trade.

Commissioner Chamberlain says that he does not think that it is an exaggerated statement to say that foreign interests have been enriched by over twenty-eight billion dollars by carrying American commerce in their ships during the last one hundred years notwithstanding the fact that we carried a very large portion of our commerce in our own ships up to 1860. Outside of the many other valid arguments for an adequate merchant marine, the amount of money that our own ships can retain in this country is an ample reason for supporting the President's plan of Government aid to our merchant shipping.

Shipping Bill Making Progress

AS a result of the efficient cooperation of the Shipping Board with the Senate Committee on Commerce and the House Committee on the Merchant Marine and Fisheries, there was introduced in both Houses of Congress, on the same day that the President delivered his message, identical bills to amend and supplement the Merchant Marine Act of 1920 embodying the Administration's recommendations for the purpose of aiding and establishing our merchant shipping.

This close cooperation was possible because the President was assisted in the preparation of his message by the facts bearing on our merchant marine that had been collected by the United States Shipping Board who in turn had been assisted by committees consisting of eleven of the best known shipping experts in this country. It is a striking tribute to the broad minded character of the personnel of the Shipping Board, composed as it is of three Democrats and four Republicans, that the findings presented to the President received the unanimous support of that body. Few, if any, know the politics of the eleven experts and it is said that the board itself was ignorant of the political affiliations of its advisers.

Thus the Shipping Bill, which is analyzed on page 219 of this issue, has been constructed by men having the patriotic purpose of securing the best information possible relating to marine matters from the best possible sources. That the work was well done is evident from the unqualified endorsement of the President's message by the convention of the National Merchant Marine Association on March 4. At this convention, which was attended by prominent men representing all branches of shipping, no criticism of the provisions of the Shipping Bill were made although one session was an open forum maintained for the very purpose of debating the provisions of this bill.

There are always bound to be honest differences of opinion in any group of people as to the best means to accomplish a great object and shipping men in the past have been no exception to this rule. However, the necessity and demand for an immediate decision on a constructive marine policy has become so great that criticism of the Administration's plan demands a suggestion of something better. It is a good bill and the indications are that it will receive the support of both Republicans and Democrats.

The Cart Before the Horse

THE natural way for a country to develop its merchant marine is to establish merchandising and banking connections abroad and then to construct its ships as fast as they are needed to handle the business obtained. The reason that this method has not been applied to any large extent by this country in the past lies principally in the far greater rewards offered to capital for domestic investment.

It was hardly to be expected, with the opportunities for exploiting our natural resources or engaging in our highly protected industries, that capital could see any attraction in shipping—our one and only free trade experiment. We did not realize that our periodical business depressions were in a large part due to the backing up of surplus products that could have been marketed in foreign countries, if we had had the business connections and an adequate merchant marine to dispose of our excess production.

Of course, if it had not been for the war we would not have built our great fleet before establishing business connections throughout the world; thus getting the cart before the horse. But we have the ships now—ready for business—and we have got to develop the traffic for them or suffer a heavy deficit until we do.

If the knowledge that our surplus vessels will cost us tremendous sums of money unless we find cargoes for them, together with the growing realization of the necessity of an adequate merchant marine both in time of peace and in time of war, is a sufficient incentive to induce us to go after foreign trade in the characteristic American fashion, then these vessels will indeed be a blessing. The opportunities for development and expansion in this country are growing less each year and America cannot take its proper place in the world, if it neglects the opportunity to secure its share of the foreign trade which can only be accomplished through American agencies and an American owned and operated merchant marine.

Joseph W. Powell

A VOTE of thanks is due to Joe Powell, as he is familiarly known in the shipbuilding industry, for the valuable assistance that he has given to the Shipping Board and to the country during the past seven months. We say seven months, because, although he resigned the position of President of the Emergency Fleet Corporation on March 4, he then accepted a final commission to inspect the ex-German passenger ships for the purpose of determining which of these vessels it would pay to recondition. His report on this matter, in view of the dearth of passenger vessels under the American flag, will be read with interest.

It is understood that Mr. Powell was very reluctant to accept a position with the Shipping Board as he was probably well aware of the acrimonious criticism that had been constantly directed against the men holding similar jobs in the past but when Mr. Lasker personally asked him if he would not come down to Washington for a short time and help straighten things out, Mr. Powell could not refuse, and so he agreed to accept the job for three months on condition that his service would be gratuitous.

At the end of three months, he agreed to a like extension and it was probably largely due to this extension that Mr. Lasker was able to place before the sub-committee on appropriations a more complete analysis of the condition and needs of the Shipping Board than that committee had ever received before from any Government department.

Mr. Powell has been a strong advocate of a protected merchant marine. He has always claimed that our shipping was an asset—not a thing to be salvaged—and that without it the United States could not take its proper place among the nations of the world. We feel that the critical period of our merchant marine has passed and that slow and sure development along the lines that Mr. Powell has urged is now in sight.

Keep The Government Out Of Ship Repairing!

ONE of the greatest reasons why the Shipping Bill will be passed by the present Congress is that, by granting the direct and indirect aids that are necessary to influence private capital into embarking on shipping ventures, the Government will be able to sell its ships and thereby put a stop to the monthly losses of several million dollars which have and always will occur under Government management of our shipping.

How then can we reconcile or explain the fact that, while Congress directs the Shipping Board to have the primary object of developing a privately owned and operated merchant marine on the one hand, it at the same time entertains an amendment to the Independent Offices Appropriation Bill directing that no part of the money appropriated in the bill shall be used for the repair or reconditioning of any vessel unless reasonable opportunity has been given to Government navy yards to submit estimates on the work?

Does it not show when such a man as Senator Lodge, who is referred to as the scholar of the Senate, seeks political advantage in such a matter as his recent attempt to secure legislation that would have compelled the Shipping Board to send the *Leviathan* to the Boston navy yard that eternal vigilance and prompt action by both individuals and associations working for the good of the merchant marine are necessary?

If the Government is to engage in repair work, why not the municipality? New York city, for instance, is contemplating the construction of a huge dry dock while the concerns in this port who have spent large sums of money to give the Government and private owners the facilities

they require are operating their plants only about half time. With competition as keen as it is at the present time in the ship repair business, it is obvious that any work of this nature allotted to public institutions on an estimate that is lower than the bids of private concerns will cause deficits that the taxpayer will be called upon to make good. If sectional politics is strong enough to defeat the will of the people as expressed in the Jones Act to get the Government out of the shipping business, then it is high time that the public should be informed of the matter so that they may again express their opinion on this subject at the next election.

Financing Foreign Trade

THE outstanding unsolved problem today is the financing of foreign trade. The Shipping Bill if enacted into law will enable American ships to compete with foreign vessels for available cargoes and it will also create a strong inducement for the exporter and importer to ship their goods in American bottoms. It will not, however, solve the question of how European countries are going to pay us for our exports. We do not want any more gold, for every ounce of it that we take weakens the exchange ratios and delays, so much longer, the time that foreign currencies may be reestablished on a gold basis. Our immigration law has reduced the inflow of foreign labor to a minimum that would sell its services and return the major portion of the money it earns to its home country. Our own unemployment problem makes this restriction a necessity although we are not unmindful of the debt that we owe to immigrant labor for the aid that it has given us in developing our vast industries. Nor can we permit the unrestricted dumping of foreign products that would close our factories and deprive our own labor of employment.

There remains, then, the importation of such goods or raw materials as are not obtainable in this country, the importation of such things as we do not raise or produce in sufficient quantity for our consumption and the importation of goods for re-export. However, it is not probable that these three factors could be developed sufficiently in time without liberal extensions of foreign credit to relieve underproduction here or abroad.

Although Europe financed us until we were able to stand upon our own feet, it is not so much a question of returning the obligation as it is a question of preventing a lowering of our standard of living. We have got to the point where we must either curtail production or export our surplus. We can export this surplus in ever increasing quantities and in direct ratio to the improvement of the standards in other countries. Unfortunately other Oriental countries are not as progressive as Japan, who has bought enormous quantities of goods in the world markets during the last fifty years, or our problems and Europe's problems of a surplus market would be quickly solved.

Much of the world remains undeveloped but it will not remain so. If Europe is aided in getting on her feet so that she can take her place in the march of progress, there will be no question of her ability to repay her debts but otherwise she will remain a constant menace to the whole world. The ninth National Foreign Trade Convention will meet in Philadelphia May 10, 11 and 12, when the ablest business minds of the country will concentrate on these problems. Let us hope that they will find a way to put our idle manufacturing plants, our idle ships and our unemployed to work.

Situations Wanted

ONE of the most distressing results of the present shipbuilding depression is the number of competent men skilled in all branches of this industry who are unable to find work. Not a week passes that we do not receive requests from men, many of whom we know possess more than the average ability in their particular line, to find them some opening for occupation in the business to which their lives have been devoted.

We know of no better way to assist these men in placing their qualifications before the eyes of the shipbuilding executives than through the *Positions Wanted* columns of our magazine. Marine Engineering and Shipping Age has made a special rate of 5 cents a word for such advertisements (minimum charge $1 for each insertion). This rate is far below that charged for other advertising and we have made it so in order that the man out of work can send over 5,000 messages and cover the entire shipbuilding field for the price of a luncheon.

The Hague Rules

THE National Foreign Trade Council has issued an appeal to the ocean carriers to put the Hague Rules into effect. The International Chamber of Commerce through its executive committee has approved the Hague Rules and directed that immediate steps be taken by its officers to secure the acceptance of these rules in the more than 20 countries holding membership in the International Chamber.

Although at least 20 of the most prominent British steamship lines operating between Great Britain, the United States and Canada have developed the provisions of these rules in their bills of lading for westbound traffic, they are precluded from doing this on the eastbound traffic by certain provisions of the Harter Act, which is the controlling legislation on this matter in the United States.

The Shipping Board has indicated to the Interstate Commerce Commission in connection with the consideration that that body has been giving to a through export bill of lading, that it intends to promulgate a port bill of lading in the near future, and the board has expressed the opinion that there should be no variance in essential particulars between the two bills.

As Section 19 of the Jones Act authorizes the board to only make rules and regulations affecting shipping in the foreign trade that are not in conflict with existing law, it would appear that Congress will have to pass enabling legislation which will meet the situation quicker than would a general revision of the Harter Act. It is essential and for the general interest of the country to secure as early a determination on these matters as is possible.

Now For Action!

By "Old Scotch"

President Harding has very tersely expressed the opinion that all patriotic citizens, regardless of political affiliations, should have one end in view, and that is the development of an adequate American merchant marine. Congress now has before it the Government's plan for accomplishing this end. This plan has been endorsed by practically all leading shippers, shipowners and shipbuilders. It is up to you, Mr. Reader, to tell your Congressman to give it his unqualified support.

THE President has at last spoken the long expected endorsement of the principle of Government aid to our merchant marine. He has courageously carried out his pre-election promises to leave no stone unturned to provide for our permanency on the seas.

Rumors of opposition in his own party, of the probable antagonism of the so-called "agricultural bloc," of the opening evidences of inspired propaganda from foreign sources, have not deterred him an iota from his firm resolve. He had all phases of the intricate problem of American shipping thoroughly investigated by competent committees under the auspices of the Shipping Board, and, after carefully weighing in his own mind the various pros and cons of the problem presented, he has delivered to Congress a message based on sound and logical principles and facts.

The message and supporting evidence have been thoroughly considered, and, to those who propose to combat the array of facts presented, the gratuitous advice is given to watch their steps. No proposed legislation of similar import has ever before been given the careful, scrutinizing and painstaking thought which has attended the formation of the measure now pending before Congress.

Well Begun Is Half Done

The old saying that "Well begun is half done" should apply with full force to this measure. All possible points of attack have been carefully guarded against, but none of us must forget that the unexpected very often happens, and it is the other half of the completion of the enactment of this proposed law to which all of us who are interested in the American merchant marine, must bend every effort.

Opposition is bound to arise and, in fact, is already in evidence. It behooves every one interested, and I take it that 99 percent of the readers of this magazine belong to this category, should bend every effort to lend aid to this meritorious bill. If false representations of the intent and purpose of the bill crop out in the daily papers, or in your daily conversations with people ignorant of shipping, leave no stone unturned to correct the wrong impressions which may start in those ways. Write your Congressman and Senators of your interest in the measure and give them supporting evidence of the benefit it will be to their own districts and to the country at large. The time is now here when every proponent of American shipping must show his hand and lend every assistance possible.

This is the last call, and if it fails, your jobs in shipyards, on board ships, or in the various ramifications of business connected with our shipping, will fail also. If you are out of a job now, and unfortunately many people connected with shipping are in that unfortunate predicament at this moment, here is the last chance to start up business again and get back into harness.

Most people go into the shipbuilding or ship operating game because they love it. If you are anxious to get back with your first love, you must do all you can individually and collectively to push this bill across. It will be over one way or the other in the next four months, as our Congressmen come up for re-election next fall, and in election years they don't like to linger around Washington much after July 1, as they have many fences which need mending around home from that time up till the first Tuesday in November.

Let Your Congressman Know Where You Stand

If you are out of a job now, tell your Congressman that if he can see his way clear to vote for this subsidy bill it will probably give you a chance to get another job, and, incidentally, when he is hunting around for support to retain his job in Washington, you might see your way clear to give him a boost on election day. The essence of practical politics is based on the old principle of "One good turn deserves another," so, if you want a Congressman to help you out when you are in trouble, don't forget to return the compliment when he is struggling to retain his job.

Knowing many of those gentlemen very well, I can vouch for the fact that there are no more appreciative men anywhere than the average Congressman. If you are interested in a pending measure and you write your representative telling him that you are, and the reasons why you are, he will hesitate a long while before turning you down. If you can convince him that he should vote for a certain bill, and he does vote for it, and you should write him a letter of thanks, it would be a case, as certain cartoonists describe it, of "Oh! Boy, how he do appreciate it."

It is so usual for the average citizen to condemn and speak evil of their representatives in Congress and other legislative assemblies, that a little praise and expression of appreciation now and then goes a long ways towards encouraging our chosen spokesmen on public questions. From the writer's many years of acquaintance with public men, he has drawn the conclusion that the great majority of them are honest and anxious to do the right thing. On subjects with which they are not familiar they are regular corkscrews for drawing out facts, and generally when good honest information is presented to them they vote the right way.

In the matter of this subsidy bill, we have all the facts and arguments on our side; and it is up to all of us to see that they are sown in the right field, which now is at the Capital in Washington.

If they want a good example of the benefit of a merchant marine, tell them the following incident, which fairly well illustrates the point.

One of the Many Benefits of a Merchant Marine

The good ship *George Washington*, by virtue of the recent scrap with the Kaiser, now belongs to the United States and flies the stars and stripes. A few weeks ago she started from New York with a party of American citizens on board, numbering about 650. We Americans, you know, love to travel around and visit sights about which we have read since childhood. Hence when it was advertised around the country that this American vessel would make a trip of ten

weeks' duration, during the inclement winter and spring months, up the Mediterranean, visiting the Holy Lands, Egypt and other historical places, many of our citizens dug down into their saving accounts and "coughed up" an average of $1,650 each for the pleasurable experience. One enthusiast, it is stated, paid $16,000 for the privilege of sojourning in the so-called Presidential suite during the ten weeks' tour. Another, less wealthy, is said to have made an offer for the privilege of sleeping in the barber's chair during that period, when he was informed that all staterooms had been sold. A very easy calculation will show that over one million dollars were paid for this single trip, of which, it is estimated, there will accrue a clear profit of probably $100,000 to the Shipping Board.

Of course, it is not intended to convey the impression that all trips made by Shipping Board vessels are relatively as profitable. Far from it, sad to state! The great underlying principle of this illustrative trip is that the million dollars taken from our people's savings is kept at home, and spent mostly within our own borders. The officers and crew are American citizens and support families living in our midst; the vast quantities of food purchased were bought from our own farmers and merchants; our repair yards will benefit from the necessary voyage repairs after the vessel returns; the various electrical, deck and engine room supplies were purchased from American dealers, who, before, had purchased them from manufactories scattered all over our own land. Many similar excursions have sailed forth from our home ports to foreign lands, patronized exclusively by American citizens, but can you recollect of any such making the trip under the American flag before? I cannot.

What the Subsidy Bill Will Do

Suppose, for example, that there should not be any profit for a private shipowner for a trip similar to this, which is altogether probable, as this represents exceptionally favorable circumstances, as such a trip can only be made about once a year. In other words, a private shipowner might break about even on receipts and expenditures, and hence would not be warranted in undertaking the enterprise. The proposed subsidy bill, if passed, would return him approximately $25,000 based on speed, tonnage and distance traveled, or just about enough to turn the balance from failure to success. Will it not be a good investment for the Government by the paying of that small sum to keep the expenditure of over a million dollars in our own borders?

Why our dear old Uncle Sam would collect almost that amount in the various taxes he levies on the people interested in the expedition. In addition to that, he will have a ship of inestimable value to him in time of war, maintained in peace times at private expense. As a by-product, we must give credit to a large amount of self-satisfaction and innate pride on the part of American tourists in that they can visit foreign parts on vessels owned, manned and operated by our own people.

The principle of expending a small direct sum of money or of granting direct exemptions in taxes, etc., in order to secure the expenditure of much larger amounts in certain communities, is one that is well recognized and adopted throughout our land. Just call to mind while passing through many American towns, on the railroads, the numbers of signs you see to the effect that "Free Factory Sites" are offered to any one who will establish a business in that particular town or city. Some offer exemption from taxes for a long term of years and various other inducements.

It is estimated that we spent over $500,000,000 for ocean transportation last year when business on the seas was very, very dull. We certainly are entitled to retain at least half that amount within our own borders, but we did not by any means. If we can expend directly the maximum amount of the subsidy recommended by the President, of only $32,000,000, and guarantee thereby the retention of at least $250,000,000 to spend among our own citizens, is it not from this standpoint alone a most excellent investment?

I have attempted in this series of articles to bring out the most salient points of advantage to be derived from having our own merchant marine, and I must admit that the surface only has been scratched.

President Harding has very tersely expressed the idea that all patriotic citizens, regardless of political affiliations, have one end in view and that is the permanency of an adequate American merchant marine. He also suggests that, if any one does not agree with the recommendations he has made to accomplish the object, it is up to the critic to suggest better methods of accomplishment.

I think we can all agree with the executive on that point. We, in this instance, are all from Missouri and would like to be shown the better methods, if there are any.

Geared Turbine Steamer Gouverneur General Chanzy, Built by Messrs. Cammell Laird, of Birkenhead, for the Marine Merchande, for Service Between Marseilles and Algiers. The Vessel Maintained a Speed of 19.559 Knots on Her Four-Hour Full-Power Trial

The Merchant Marine Bill of 1922 Analyzed

One of the Experts Who Assisted the Shipping Board in Framing the Bill Outlines Its Merits

By Winthrop L. Marvin*

IN form the bill "to amend and supplement the Merchant Marine Act, 1920, and for other purposes" (the new shipping bill, to be known as the Merchant Marine Act of 1922) brings varying emotions to those who study it. Maritime Europe is aghast; its "listening stations" in this country failed to predict the blow that was coming. The new bill reaches further and hits harder than our competitors by sea had imagined, but it does this without fracturing treaties or unduly provoking retaliation in kind. Suppose Great Britain, Germany and Italy reserve their emigration, as we propose to do our immigration, 50 percent to National vessels—what harm can come of that? It would be an entirely fair and reasonable arrangement all around.

Ship Sales

In the first place, it is significant that the new bill skilfully amends the ship sales section of the Jones Act of 1920 so that the Shipping Board will be freed of all restrictions as to cost of reproduction, etc., and it is directly authorized to dispose of the government-owned fleet at world-market prices. This will presumably have the support of most of the majority party in Congress, and the Democratic minority is faced with the ugly historical fact that in past years, urging a free ship policy or free purchase of vessels from abroad, it has contended that Americans should have a chance to buy their ships for foreign trade "on even terms with their competitors!" It must be remembered that the free ship provision of the Panama Canal Act of 1912 remains in force, and that American shipowners have a lawful right to buy foreign trade ships abroad, though these imported vessels, except in special cases, will not be eligible for subsidy. If any Democrats object to a "sacrifice" sale of government ships all the Republicans will have to do is to turn their own arguments against them.

Construction Loan Fund

A second important amendment of the Jones Act is provided in the new bill by the specific naming of the sum of $125,000,000 as a construction loan fund which may be availed of either for the building of vessels "of the best and most efficient type, equipped with the most modern, the most efficient and the most economical machinery and commercial appliances," or "in the equipment of vessels already built with machinery and commercial appliances of the type and kind mentioned." Under this provision it is anticipated that powerful aid will be given to the construction of fast liners in which we are so notably deficient, and to the construction or equipment of motorships. This is a fair interpretation of the purpose in the minds of the authors of the present measure. Very liberal are the limitations that "no loan shall be for a greater sum than two-thirds of the cost of the vessel to be constructed or of the value of the vessel when thus re-equipped, nor shall any loan be made at a rate of interest less than 2 percent per annum."

It is to be remembered that when the British government in 1903 loaned to the Cunard Company $13,000,000 to build the *Mauretania* and *Lusitania*, the rate of interest was 2¾ percent.

Another liberalizing amendment of undeniable value to shipowners is the change made in Section 23 of the Act of 1920, providing that for ten years for the purpose of ascertaining net income subject to the war profits and excess profits taxes of the Act of 1918, or any and all taxes on income of the Act of 1921 or any subsequent Act, the deduction of an amount equivalent to the net earnings of vessels in the foreign trade. It is stipulated that the amount of such deduction shall be pledged to the building of new ships in the United States, one-half of the cost of such ships to be paid for out of the ordinary funds or capital of the owner. The Jones Act required that two-thirds should be of new capital. A similar deduction is provided for owners that may sell vessels built prior to January 1, 1914, under Title I, II and III of the Revenue Act of 1921—this again on condition of new construction in American yards. Thus these features of the Jones Act are made distinctly more valuable.

Deduction for Shippers Using American Vessels

A wholly new feature of American maritime law is that provided for in Section 301 of the new shipping bill for a deduction from the amount which would otherwise constitute the income tax of a sum equivalent to 5 percent of ocean freight money paid for transportation of merchandise in American ships in the foreign trade. This is an ingenious new departure intended to serve the purpose of a part of the preferential duty of the original Jones Act—but, as a matter of fact, it is far more valuable and effective, for it would apply to all merchandise, dutiable or free, inward or outward.

This is treaty-proof. It is not a subsidy, but an indirect aid. Its potential importance is incalculable. It will appeal to all shippers small and large, and will have the effect of making all American vessels first-preferred bottoms. This is one thing which our foreign competitors have been sharply worrying about. They had not expected this new scheme and do not even yet know how to take it. It would apply to the benefit of the entire American merchant marine engaged in foreign trade—"tramps" as well as liners, in proportion to the freight moneys received, which, per actual cost of ship, are far greater in "tramps" than in liners. This may be regarded, therefore, as distinctively encouragement to the slower cargo ships and as a material addition to their modest subsidy.

Of great though not easily appraised value also is the provision of Section 302 allowing more equitable allowance for the extraordinary depreciation in vessel property since January 1, 1921. In Section 303 tonnage taxes on all ships, American and foreign, are doubled, but the revenue goes to the merchant marine fund for the benefit of American shipping.

Assures 50 Percent of Immigration for American Ships

It is to be assumed that the language of Section 401, the purpose of which is to reserve at least 50 percent of immigration to vessels of the United States, has been carefully studied by its authors. The language is technical, but the ways and means of enforcing this proposal must be somewhat complex. Fifty percent of the immigration year after year will go far to make at least 50 percent of the transatlantic passenger liners American, for the overwhelming American majority of cabin passengers will naturally seek

*Vice-president and general manager of the American Steamship Owners' Association, New York.

American ships as soon as an adequate service is created. This is a bar to any growth beyond a certain point of the former huge German steamship concerns, and is apparently a barrier to any further growth on the part of the Cunard Line and its auxiliaries. But the provision is, after all, fundamentally a right one. The United States must have a sufficient naval reserve to maintain its naval standing under the limitation of naval armament. The greatest of these naval reserve steamers are to be sought on the transatlantic routes.

Provides for Naval Reserve

Moreover, these naval reserve ships must be fitly officered and manned in an emergency. This gives a vital value to Section 501 of the new bill, with its assurance of a merchant marine and naval reserve of picked officers and seamen of our merchant service who, after the British example, will receive retainers from the Government. Great Britain before the war had more than 30,000 enrolled in her merchant reserve. We must have an equal number, for we will have equal need. Of course the foreign agitators of the "International" Seamen's Union will fight it—but the time is not now when these gentry can hope to veto the possession of a naval reserve by the United States. President Harding on his own initiative decided months ago to turn the army and navy transport service over to the American merchant marine. Section 601 of the new bill arms him with power to do this of which he is already possessed. However, this is an essential part of any constructive National maritime policy, regardless of other provisions.

The Subsidy

Under the accurate heading "Compensation" rather than "Subsidy," Section 701 provides for carefully graduated mileage payments to "every sail or power-driven vessel of 1,500 gross tons or more, documented under the laws of the United States and operated in foreign trade." Inclusion of good sail craft is justified, for they are performing a useful service, though their numbers will not further increase. A basic rate of compensation is one-half of one cent for each gross ton for each 100 nautical miles traveled—this applying to all ships capable of a speed on light draft up to 13 knots—that is to say, this covers the great bulk or almost all of the cargo-carrying ocean tonnage of the United States. At 13 knots the increase for speed begins with a rate of two-tenths of one cent for each gross ton per 100 miles traveled—and so on step by step up to a rate of two and six-tenths cents for great liners driving at a speed of 23 knots or over.

This compensation, payable on both outward and homeward voyages, is a higher amount than has been hitherto proposed for liners, but, on the other hand, these ships must carry the mails without pay. Under the circumstances, therefore, this compensation, save for exceptionally large, high-speed ships, can be regarded as only moderate.

It may even fall short in the case of some indispensable services, as to South America and the Orient, for example. But in such cases a further provision of the bill in the final paragraph of Section 702 authorizes the Shipping Board to increase the compensation as may be necessary to secure the maintenance of indispensable services, the increased compensation, however, not to exceed twice the regular rate. Moreover, the Shipping Board is authorized to reduce any compensation found excessive.

These elastic features of the compensation portion of the bill, together with the limitation on profits in one of the paragraphs of Section 703, are unique in American shipping legislation. A State-aided ship may not realize a net operating profit of more than 10 percent. This is a legislative experiment that may prove unwise in its result, though it will undoubtedly facilitate the passage of the bill by Congress. Mid-Western Senators and Representatives are frankly recognizing this new bill as "something different," and as satisfying their scruples against excessive subsidies. However reluctant the seacoast States may be to recognize this statutory limitation, it may perhaps prove to be the winning of the law.

The Merchant Marine Fund

Into the merchant marine fund must go 10 percent of the customs receipts, and the increased tonnage taxes, together about $34,000,000 annually—and also the compensation which under the 10 percent limitation may have to be paid back. A very important clause is Section 702 authorizing the Shipping Board to conclude a ten-year contract with shipowners, on behalf of the United States. Therefore, the bill, if once enacted, cannot be easily set aside.

Under one of the provisions of Section 701 oil tank carriers and like craft owned by great producing companies are required to hold open until ten days before sailing "substantially one-third" of their cargo capacity for use as a common carrier, in order to be eligible to the compensation provided. Here again is a provision manifestly inserted to smooth the passage of the bill to meet objections certain to be raised by a certain class of lawmakers. This is another novel feature of the bill which cannot easily be analyzed until it is actually working in practice. It is good expert opinion, however, that the tank and other ships need not be embarrassed, if the provision is enforced in a reasonable spirit.

Philippine trade receives exceptional favors in the bill, anticipating the application of the coastwise laws as ordered in the Act of 1920. The new bill nevertheless stipulates that "trade between the United States and the Philippine Islands * * * shall be considered foreign trade, whether covered by the coastwise laws or not." This would permit the granting of the compensation of the new bill to American ships in the Philippine trade, though their trade was technically coastwise. It is manifestly the purpose of the Administration to make sure that our Philippine commerce is guaranteed most favorable treatment, because of the distance that lies between the islands and the American mainland. Under the shelter of the coastwise law, and with subsidies besides, there can be no shadow of a doubt that our Philippine carrying trade will henceforth be notably efficient and prosperous.

Altogether the proposed Merchant Marine Act of 1922 does more for the American merchant marine than any like measure ever contemplated. Defects of detail it may have—these can be corrected. But the bill itself, if enacted in substance, will prove a Magna Charta of the ocean shipping trade of the United States.

The indirect aids of the bill are very powerful, but by themselves they are not sufficient. The direct compensation to liners and to cargo craft is absolutely indispensable to the complete success of this significant measure. Without that compensation the competition of low-wage and often subsidized and bountied foreign flag ships cannot be successfully met. Congress must accept the bill as a whole, in order to deal justly and effectively with the long-disputed but still unsolved problem of American shipping in the overseas trade.

Shipping Board Dry Docks for Sale.—Announcement is made that the contracts with pioneer purchasers of Shipping Board dry docks have been canceled. Contracts, or the docks themselves, will soon be advertised for sale to the original holders of the contracts. These docks cost an average of $900,000 each, but will not bring more than $350,000 today, it was estimated. All are 10,000-ton docks on the Atlantic and Gulf coasts, some of them being at Baltimore, Norfolk, New Orleans, New York, Perth Amboy, Mobile, Galveston, Jacksonville and Weehawken.

Early Hearings on Shipping Bill Promised

Democrats Urged to Be Non-Partisan—Independent Offices' Appropriation Bill Reported to House—Shipping Board Reduces Expenses

By Harold F. Lane

LEGISLATIVE consideration of the administration's plan for extending direct and indirect aids to American shipping is about to begin in earnest. Hearings on the merchant marine bill before the Senate Committee on Commerce and the House Committee on Merchant Marine and Fisheries, sitting jointly, are expected to begin before this issue of MARINE ENGINEERING AND SHIPPING AGE reaches its readers. Commissioners of the Shipping Board, who have unanimously approved the plan recommended in the President's message of February 28, are to appear as witnesses, as will many of the members of the committee of experts who assisted the board in its preliminary study on which the plan was based. Representatives of the shipping and other industries also are to be heard.

It is announced that the hearings will begin on March 28. It is the hope of members of the committee that they can be concluded in about three weeks' time although adjournments from time to time may spread them over a longer period. It is expected that Chairman Lasker will be the first witness. Copies of the bill have been submitted to the chairmen of other committees who have jurisdiction over some of the various subjects included in the bill, such as the ways and means committee, committee on naval affairs, the immigration committee and the committee on interstate and foreign commerce.

The Democratic members of the Shipping Board, George E. Chamberlain, Frederick I. Thompson and W. S. Benson, on March 6 addressed a letter to the members of the two committees, emphasizing the fact that the recommendations of the board to the President were based upon an intimate study made by the board, without political considerations, and urging the Democratic Congressmen to treat the subject in a non-partisan manner, withholding judgment until after full hearing. The letter said that the members of the board were governed solely by the real questions involved, as follows:

"1. The necessity for maintaining a merchant marine, developed from the immense fleet called into existence by the emergencies of war.

"2. The necessary action to be taken to assure to the United States its former position and prestige on the high seas.

"Aside from the economic necessity for the establishment of an adequate merchant marine under the American flag, deep consideration was given to that aspect embodied in the merchant marine act, 1920, providing for the merchant fleet to be a naval auxiliary in time of war. It is our opinion there can be no divergence of opinion as to the necessity for the full establishment of an American merchant marine; the only question upon which there could be divergence of opinion is whether aid, either direct or indirect, or both, should be granted to accomplish that purpose. It is our opinion that the establishment of an American merchant marine will be impossible without such aid as will equalize present differentials that exist in favor of foreign shipping, and our recommendation to the President contemplated direct aid only in the event the indirect aids first suggested were inadequate to properly develop and maintain an American merchant marine, the direct aid itself being nonexistent if the indirect aid sufficed, and further limited as to profit to the ship only up to an adequate return to the operator on his investment. This assures no profiteering and brings into being direct aid only when it becomes a final essential to maintain American-flag ships on the high seas.

"We understand that there will be a joint hearing of the appropriate Senate and House committees on the bill in question, and we trust you will not deem it impertinent in us, the Democratic members of the United States Shipping Board, to suggest to you and the other Democratic members of the committees of the Senate and House to withhold a final judgment with respect to this legislation until after the hearings have been completed and full opportunity given to the members of the board to state the reasons guiding their action in unanimously recommending direct and indirect aid to American shipping, and so that the full details of the proposal submitted, which has taken many weeks of survey and consideration, shall have been placed, in all detail, clearly before you."

The joint legislative conference of the American Federation of Labor went on record at a meeting in Washington on March 10 as opposed in principle to the provisions of the administration bill and in particular to the sections providing for a merchant marine naval reserve and dealing with the question of immigration, which the committee viewed as nullifying provisions of the seamen's act.

Appropriation Bill Reported to House

The independent offices appropriation bill, carrying the appropriation for the Shipping Board and the Emergency Fleet Corporation, was reported to the House on March 15 and after considerable discussion the House voted to insist on its disagreement with the amendments inserted in the bill in the Senate regarding the continued use of the $55,000,000 and as to the number of salaries in excess of $11,000. During the course of the debate, Representative Byrns of Tennessee stated that Homer L. Ferguson, president of the Newport News Shipbuilding & Dry Dock Company, has a position at a salary of $11,000 a year as a member of the claims commission of the Shipping Board, while his company has received a large contract from the board. A statement was later issued by the board stating that Mr. Ferguson was selected by the President to serve as a member of the claims commission without salary, but that he has at no time sat with the commission and has taken no part in its work on account of his connection with the Newport News company, which company has claims against the Emergency Fleet Corporation, until all the claims in which his company may be interested have been finally concluded.

The conferees submitted a report on March 9 which showed that they had not yet reached a complete agreement on the conflicting provisions of the House and Senate bills, and were given instructions to continue the conference. They had agreed to insert the language proposed by the Senate, providing that no part of the moneys appropriated or made available shall be used for the repair or reconditioning of any vessel until a reasonable opportunity has been given to the available Government navy yards to estimate upon the cost of such work, modified so as to permit the Government arsenals to bid on such work, and further modified so as to require estimates from the navy yards or arsenals when the expenses of such repair or reconditioning is in excess of $100,000, instead of

$5,000, as proposed by the Senate. They had also agreed to strike out, as proposed by the Senate, the provision that no part of the sums appropriated shall be used to pay a greater sum than 5 percent as commissions for the placing of advertising matter contracted for; and the matter, inserted by the Senate, modifying the limitation placed by the House upon the appropriation for the payment of claims by the Shipping Board or Emergency Fleet Corporation; also, as proposed by the Senate, the prohibition of the use of Shipping Board or Fleet Corporation funds for the printing of "bulletins."

Shipping Board Reduces Expenses

On the eve of his retirement from active service as president of the Emergency Fleet Corporation on March 4, Joseph W. Powell issued a statement announcing that the Shipping Board had liquidated $20,373,000 of its assets and had reduced its personnel by 3,302, saving $5,290,000 on payrolls, including $1,324,000 on caretakers. Its operating costs have been reduced by $900,000 a month and the insurance, repair, voyage and lay-up costs as well as general administrative expenses have also been reduced in the last six months.

Detailing the progress made in liquidation since his assumption of office last August, Mr. Powell said that on laid-up ships, which had increased from 950 to 1,278, a saving of $1,324,000 had been made; ships had been sold for $5,000,000, houses for $6,073,000, surplus materials for $5,000,000, and securities and mortgages for $4,300,000, a total of over $20,000,000.

Voyage expenses were reduced from $1,896,000 in July, 1921, to $934,000 in January, 1922. Repairs and betterments, costing $1,467,000 last July, cost only $950,000 in January, even though 30 ships were broken out and repaired for the Russian grain. Insurance on ships, Mr. Powell said, had dropped from $578,000 in July to $416,000 in January, while expenses for lay-up fell off $139,000 during the six months. Administrative expenditures during the past month had dropped from $906,000 to $678,000, he said. Total expenses in December were $4,137,000 and for January were $3,445,000.

For February it had been reported that, whereas the Shipping Board paid its operators $6,400,000, a return of $6,500,000 had been received indicating a cash income of over $100,000 for the month, whereas a deficit has been the case heretofore.

Newspaper publication of this statement, however, made it necessary for Mr. Powell to explain, in a letter to Representative Wood of the House appropriations committee, that the statement did not mean that the Fleet Corporation was making a profit and had no relation to the operating showing for the month, but merely referred to the manner in which it was husbanding its cash and keeping careful check on the outlays by operators.

Mr. Powell's Explanation

"As a matter of fact, as both Mr. Lasker and I repeatedly testified before your Appropriations Subcommittee," Mr. Powell said, "the Shipping Board is losing between $3,000,000 and $4,000,000 per month. Regardless of bettering conditions which now exist in freights, the loss of the Shipping Board for some time to come will continue constant at the approximate $4,000,000 figure, because vast sums are being paid out at the present time for insurance due from the past, of which we knew nothing until within the last two weeks. Yesterday Mr. Lasker paid out $2,000,000 for P. & I. insurance due from prior periods to the present board's incumbency, of which no record existed and of which no knowledge came to the board until two weeks ago. Also, during the period between August and January, when freights were scarce and rates soft, very little work was done on the tied-up fleet, because Mr. Lasker desired to husband the cash resources of the Shipping Board so as to come within the limitations of appropriations. It is for that reason that the expenditures on the tied-up fleet, referred to in the article attached, were so low, operating as we were a lesser number of ships than we had been, and having taken out at first the best ships.

"From now on there will be comparatively large expense in repairs in further ships we take out of tie-up and in putting necessary reconditioning into some of the tied-up ships. All this was deferred during the period when voyage losses were so great; but, now that conditions are better and voyage losses will be lessened, repairs to the tied-up fleet can no longer be deferred. For this reason the loss will be constant at around $4,000,000 a month, as testified to by Mr. Lasker and myself. In other words, during those periods when voyage losses are great, we cannot do necessary repairs to the tied-up fleet. Whenever we get relief from voyage losses, the tied-up fleet is repaired. So that according to this policy of Mr. Lasker's, the Fleet Corporation will keep within appropriations, keep trade routes going, and keep its tied-up fleet in condition.

"Permit me further to call to your attention that while it is true, as the article states, that we have liquidated some $20,000,000 worth of assets since the new board came into office, only $7,045,490 has been collected on same, of which $1,500,000 came in last week. The balance of the moneys on liquidated items are due, either in part before July first next or extend over long periods. A careful estimate made yesterday, which was submitted to me last night, would indicate that the amount that we can surely count upon to be realized in cash from liquidation between now and July first will be approximately $25,000,000, as stated in our testimony before your committee. There is a vast difference between cash received from liquidation before July first and amount of goods liquidated, which are sold for part cash and part on long time."

Mr. Powell, in resigning his office, in which he was serving without salary, agreed to undertake one commission for the board, a survey of the 30 former German ships, most of which are docked at Philadelphia, to determine which appear advisable for the board to recondition with a view to offering them for sale.

Commission Modifies Export Bill of Lading

The Interstate Commerce Commission has issued an order modifying in certain particulars conditions in its export bill of lading upon recommendations made by the United States Shipping Board, after a hearing at which the board was represented by counsel and Vice-President W. J. Love of the Emergency Fleet Corporation. The board has approved the bill of lading as thus amended and agrees that it should not be put into effect until July 15. The board also approved the bill of lading prescribed by the former order of the commission, to be used until that date.

The Interstate Commerce Commission has also issued an order in accordance with Section 441 of the Transportation Act designating points on railroads at which information relative to the handling of export shipments by common carriers by water in foreign commerce shall be maintained and at which through bills of lading to foreign destinations in connection with ocean carriers, whose vessels are registered under the laws of the United States to points in non-adjacent foreign countries, shall be issued.

Increased Cargo Offerings.—J. Barstow Smull, vice-president of the Emergency Fleet Corporation, is receiving many inquiries from M. O. 4 operators at Gulf and Atlantic ports for more ships, showing an increase in cargo offerings. It is the policy of the Shipping Board not to furnish ships, however, unless the operators can demonstrate that they will be able to show a profit or at least earn expenses.

Shipping and Shipbuilding in Great Britain

England Sees Danger in Portugal's Example of Flag Discrimination—Abolition of Income Tax for Shipping Advocated

By W. H. Wendon

THE most widely discussed subject in shipping circles at the present time is in regard to what at first blush is a question of minor importance. I refer to the Portuguese Government's decree which imposes in several different ways a most severe handicap on the ships of foreign nations calling at Portuguese ports. The comparative unimportance of the trade of any country with Portugal would, of course, be sufficient in ordinary circumstances to render the decree beneath the notice of the major maritime nations. But the shipping community in this country is fearful that the bad example which Portugal has thought fit to set is fraught with serious consequences. Indeed, if the project is not nipped in the bud, it is regarded as inevitable that other nations will follow suit and that the principal maritime countries of the world will be at each other's throats on the question of flag discrimination.

Sir Kenneth Anderson, the head of the Orient Line, to quote only one shipping authority, maintains that it is imperative that British shipowners should, with all possible emphasis register their protest at the action of Portugal and reaffirm the conviction of owners here that, not only in the interests of British shipowners but in the interests of all shipowners and in the interests of the whole world-wide community, irrespective of nationality, trade or profession, such a policy must prove ultimately injurious.

Discrimination an Obstacle to Exchange

The effects of discrimination are obviously manifold. It is an obstacle to exchange and automatically increases the cost and the scarcity of commodities and services. In short, as Sir Kenneth Anderson stated recently at the annual conference of the Chamber of Shipping of the United Kingdom, discrimination invites the world to a game of "Beggar my neighbor," in which all must lose and none can gain. A disturbing feature of Portugal's action is the belief that she has been inspired to adopt her new policy at the direct or indirect persuasion of Germany.

A representative body of shipowners in London has unanimously resolved to urge the British Government to direct the attention of foreign governments who have recently adopted or threatened measures of flag discrimination to the prejudicial reaction of such measures on the trade of the world and to the unreasonableness of expecting a continuance of the free navigation and equal trading rights hitherto accorded by the British Empire in the face of measures hurtful to its shipping.

Levying of Income Tax on Shipping of Other Countries

Another subject of the greatest importance to shipowners in all countries is the levying of taxation abroad. Shipowners in Great Britain advocate the abolition of international income tax, by which expression is meant each country levying income tax on the shipping of every other country. Each country necessarily differs in its system of taxation, so that a ship proceeding from, say, Antwerp to the River Plate might have seven different countries to placate, seven bundles of forms to fill in, accompanied by seven different penalties.

Then there is the fallacy lying in the assumption that by calling at a port the owner of the ship is making a profit out of that country in which the port is situated. Whereas, in fact, the owner is spending money all the time his boat is in port. Fiscal taxes should, therefore, it is urged, be payable only to the country to which the ship belongs.

America Takes Initial Step

The greatest praise is due to America for having taken the initial step in the abolition of these taxes. In her Revenue Act of 1921, passed in November last, Congress exempted from tax the income of a foreign shipowner, provided an equivalent exemption is granted to the citizens of the United States. British shipowners have pronounced in favor of petitioning the Government to seize the opportunity afforded by America and of putting an end to this international taxation conflict. The slogan of British shipowners is: "The profits of shipping are earned on the high seas and as such are taxable only in the country of domicile."

Port and Harbor Dues

A vigorous campaign is being conducted in Great Britain to secure a substantial reduction in port and harbor dues. The Chamber of Shipping has expressed its views with no uncertain voice and it has the backing of the principal industrial associations in the British Isles. Thus, the Federation of British Industries, a young but decidedly go-ahead body, has communicated its opinions to the port authorities of London, Liverpool, Manchester, Hull and Dundee. It points to the fact that, when a survey is made of the charges prevailing at the different ports and docks, it is found that only one or two of these have charges standing at less than 100 percent above the pre-war level, while, in the great majority of cases, the charges range from 100 to 150 percent above 1914 and in some instances even exceed this figure.

The contention of traders is that the port and harbor charges are not only quite out of relation to the general level of prices prevailing in this country, but that they give no adequate reflection of the direct advantages which have accrued to the dock companies through the fall in the price of the material which they consume. There is, therefore, the grave danger of shipowners being still further handicapped in their efforts to reduce freights to meet the demands of British manufacturers and exporters, and the consequent diversion of traffic from the United Kingdom to Continental ports, where charges are on an appreciably lower scale.

The Federation of British Industries hopes, as a result of its protest, to obtain a reduction in port and harbor charges of at least fifty percent. They will, however, not attain their object without a struggle. The dock and harbor proprietors, for their part, are convinced that their charges are no higher than are justified, Lord Devonport, the chairman of the Port of London Authority, declaring that, if the authorities were to reduce their charges in the manner proposed, they would be heading straight for the bankruptcy court.

"Survival of Fittest" Still Continues in Shipping

In the United Kingdom shipowning world in general, and Cardiff in particular, the survival of the fittest continues. Another late boom single ship concern—the Glynn Shipping Company, of Cardiff—has met with disaster, the mortgagors having exercised their rights by taking possession of the company's 5,200-ton deadweight steamer. The company has

other liabilities to the tune of £27,500, of which £23,000 is due to the tax authorities and £4,000 to bankers. The profits secured during the company's first year's trading ending August 31, 1920, were £33,575, of which £15,000 was reserved for taxation and depreciation, and a dividend of 12½ percent paid. As a result of the second year's working a profit of £18,239 accrued, and a dividend of 2½ percent was distributed. The affairs of this company are typical of so many other concerns formed during the period of inflated ship values.

Reduction in Ship Repair Costs Urged

Shipowners are counselling the urgency of securing a reduction in costs in another direction, namely, ship repairs, which are still costing this country far more than in pre-war days and are appreciably higher than in some Continental countries. Sir Frederick Lewis, the newly-elected president of the Chamber of Shipping, thinks it may safely be said that many vessels are now lying unrepaired because the cost of repairs would exceed the value of the ships when repaired.

Tonnage Laid Up

An estimate of the British tonnage at present laid up in the United Kingdom puts the figure at 2,250,000 tons gross, while the United States Shipping Board (apart from privately owned vessels, wooden and composite vessels) is stated to have some 1,000 ships lying idle, representing possibly something over 4,000,000 tons gross, other maritime countries, of course, being in much the same unfortunate position. Incidentally, there are 30,000 British merchant marine officers and seamen without employment at the present time. Sir Frederick Lewis put the shipping depression question in a nutshell when he confessed that he had no sovereign remedy for it. He recalled that schemes for proportionate laying up of tonnage, for breaking up, or even sinking, old and obsolete tonnage have all been canvassed, but that these schemes, excellent in their way, all start with the idea of cutting down the supply to meet the demand, whereas the aim should be to increase the demand up to and beyond the supply. He considers that the best part shipowners can play is in reducing operating costs to a minimum and raising the efficiency of cargo handling in ports to a maximum.

German Shipyards Busy

An absurdity of the tonnage position is that, despite the huge excess of cargo space in vessels, judged by the present lack of freight offering, coupled with the fact that it costs more to build new vessels—even in Germany—than they can be bought for second-hand, German shipyards are still turning out a large volume of new tonnage, a great deal of the expenditure on material and labor thereby involved being pure waste.

Shipbuilding Faces Labor Crisis

The shipbuilding and engineering industries of Great Britain are in much the same dull position as of late. Indeed, in regard to engineering, something like a crisis prevails on the much-debated question of the rights of trade unions to decide when members of their organizations shall or shall not work overtime. The view of employers is that no trade union should be in a position to interfere with the right of employers to exercise managerial functions in their establishments, while employers for their part shall not interfere with the proper functions of the trade union. The subject has caused serious controversy in the past and it is generally hoped that engineering employers will make a great effort to secure once and for all a definite understanding with the unions on this point.

King George Interested in Navagation Congress

The King has consented to become patron of the Congress to be held in London, under the auspices of the International Association of Navigation Congresses, in 1923. Lord Desborough will be president of the Congress, which will be attended by the leading representatives of dock, harbor, shipping and inland navigation authorities of the chief countries of the world.

Philadelphia Fireboat J. Hampton Moore, Recently Built by the Merchant Shipbuilding Corporation, Chester, Pa.

The vessel is 120 feet 9 inches long over all, 28 feet beam, 12 feet 9 inches depth and on a draft of 9 feet has a speed of 14 miles per hour. Her equipment consists of four turbine fire pumps, one main water tower 30 feet above the main deck and two small towers 15 feet above the main deck. On top of each deck and on top of the pilot house there is a 3000-gallon monitor nozzle designed to operate at a working pressure of 250 pounds. The four pumps are capable of throwing 10,000 gallons of water per minute against a head of 200 pounds.

Developments in Marine Insurance

Rating Shipping Board Vessels—Seaworthiness—Safety Rates—New Lake Carrier Type—Ice-Closed Ports

By "Bordereaux"

CLASSIFYING Shipping Board vessels for purposes of equitable rating is one of the most conspicuous problems now engaging marine underwriting attention. And it has to be confessed that in spite of the experiments constantly made during the last year or more it still remains a problem. To date, neither the insurers nor the insured have been satisfied with the results. This, upon reflection, will be seen to be unremarkable, because the Shipping Board's insurance problem is an extremely delicate one. Friends of the Board believe that Shipping Board vessels should be rated on the same basis as the old experienced liners; but the underwriters can not see it that way, in view of the lack of any extended experience back of the former's boats upon which the underwriters can safely construct conditions and rates closely approximating those regularly given the older lines. Even to approach the preferential or parallel basis desired by the champions of the Shipping Board boats there would have to be devoted to the problem close study by the ablest men in the insurance business in America.

And that is precisely what is going to be done now. A week or two ago Vice-President W. J. Love, of the Shipping Board, met in New York with a number of prominent marine underwriters who handle the bulk of the ocean cargo coverage of this market and consulted with them upon the best means for attaining the end so much desired by both sides of this controversy. The result was the holding of a meeting the following morning at the offices of the American Marine Insurance Syndicates at which practically every leading New York marine underwriter was present. A committee was appointed to grapple with this problem, consisting of the following eminent underwriters: Hendon Chubb, William H. McGee, Louis F. Burke, E. W. S. Morren, W. L. H. Simpson, J. E. Hoffman, F. H. Cauty, G. C. Moore, G. Brenker, C. R. Ebert, Samuel Bird, W. J. Roberts, S. D. McComb, C. A. Orr, D. F. Cox, A. F. Post, Jesse Spier, W. W. Parsons, George C. Owens and Charles R. Page, chairman. This group is representative not only of the leading American companies but of the foremost admitted foreign institutions as well. The committee, in turn, chose William H. McGee, Hendon Chubb and Charles R. Page as its conferees to confer with a similar group to be appointed by the Shipping Board.

The purpose of the appointment of this committee is to investigate carefully and impartially the conditions under which lines operated by the Shipping Board in competition with either American or foreign-owned private lines are operated and to recommend to underwriters generally the adoption of classifications which will tend to sweep away any differentials which may no longer be justified.

It is the general feeling of the underwriting community that Shipping Board vessels when operated in competition with privately-owned vessels are entitled to the utmost consideration at their hands and, whenever and wherever conditions will permit, the underwriters aim to put such vessels on a rating parity with other similar tonnage with which they may be in competition.

As it is well-recognized that the Government-owned vessels can seek only to be placed upon a parity of rating with their privately-owned competitors, it is hoped that as a result of the careful investigation of the facts which is being immediately undertaken, the committee may be able to recommend to underwriters the adoption of a classification basis which will give due recognition to the much improved conditions under which the Government-owned vessels are now operated.

As soon as the committee has been provided by the Shipping Board with the information essential to the prosecution of its investigations the former will proceed through the medium of several smaller committees to a careful investigation of the type and character of the vessels, both privately-owned and Shipping Board owned, engaged in various trades, and also to enquire carefully into the experience of the various managements. Upon the result of these investigations will depend the recommendations of the committee.

Marine Syndicates Annual Meeting

THE annual meeting of the American Marine Insurance Syndicates and of the United States Salvage Association was held on March 9. The fact that this was the first meeting at which the results of a full year could be presented, in view of the brief period in which the Syndicates have been operating, made the occasion one of more than usual interest. Enough was shown to abundantly establish the financial success of these important adjuncts to American hull underwriting. The latest figures, which were as of December 15 last, indicate that Syndicate "B" had at that time a credit of $520,000, and Syndicate "C" a credit of $1,627,000. By "credit" is meant a near approximation to profit; the precise profit can not be definitely given until the full period of the accounts has been run through. What used to be known as Syndicate "A" is now the United States Salvage Association, and this has only been in operation a matter of less than six months. W. W. Parsons, E. C. Jameson, F. H. Cauty and Lawrence J. Brengle were elected as directors of the Salvage Association for the three years ensuing to take the places of those whose terms expired in March. The Atlantic Mutual, Fireman's Fund, Globe and Rutgers, Providence-Washington and Continental were elected for three years as members of the Board of Managers. Reports were rendered by Mr. Brengle, as acting manager and chief underwriter of the Syndicates, and by Hendon Chubb as chairman of the Underwriting Committee.

Writing War Risks Again

DISTURBED conditions in Egypt and India have led British underwriters to give notice under the cancellation clause in open policies that such covers as include war risks must be terminated so that a readjustment of premiums may be effected. This is because the war risk policies include the risk of strikes, riots and civil commotions—hazards that have been coming prominently to the fore in the East of late.

Seaworthiness

A PERSISTENT rumor comes from London to the effect that the underwriters of that market, upon whom fell the $1,200,000 loss sustained in the burning of the *Northern Pacific* during its run from New York

to Chester, Pa., are disposed to resist payment on the ground of unseaworthiness, based upon the report of the insufficiency of the crew. Every marine insurance contract carries the implied warranty of the seaworthiness of the vessel. This warranty means not only that the ship is structurally sound but that she is equipped with fuel, stores and a crew sufficient for the voyage upon which she is to sail. This is a question that has been before the courts time and again, and in each instance the size and capabilities of a vessel's personnel have been decided upon the requirements of the particular voyage.

It is extremely doubtful whether the courts would hold with the text-book writers in making seaworthiness a condition precedent which, if not fulfilled, prevents the attachment of the policy. The argument is frequently made that no such rule should be applied in cases where the vessel was unseaworthy at the time of sailing but unseaworthiness did not contribute to her loss. In the well known case of the *Themistocles,* when an action was brought on the bill of lading against the owner of the vessel, the court held that even though she had sailed with boilers in an unseaworthy condition yet she was lost through stress of weather and not because of the state of her boilers, and the owners were held not liable. Phillips is of opinion that if unseaworthiness is corrected before a loss arises therefrom the insurance is not of necessity voided.

Even though the crew of the *Northern Pacific* was large enough to navigate the vessel it may still be necessary to prove that the crew was sufficient to cope with such a fire as might arise in the course of her voyage.

New Type of Lake Carrier

MUCH interest is felt by marine insurers in the proposed improved type of cargo carrier which is under construction for the handling of mixed cargoes from Great Lake ports through the Barge Canal to New York. It is to have a deadweight capacity of about 4,000 tons, will be 300 feet long, 43 feet wide and 24 feet deep. A steering propeller in the bow will aid the rudder, and the engine equipment will probably be of the Diesel type. It is thought probable that this new type will be employed to compete with the proposed direct service to Atlantic ports via the St. Lawrence River.

Underwriters are also interested in the memorandum filed by the Merchants' Association with House Interstate and Foreign Commission opposing the St. Lawrence Ship Canal. This document stresses the economic character of the present lake carrier as compared with the ocean carrier, which will operate on the lakes as the ship canal becomes a reality. The former is admitted to be the most effective type of vessel in the world for the work it has to do.

Liability in Ice-Closed Ports

MATERIAL differentials are generally made by underwriters for summer and winter sailings to Baltic and other northern ports in order to compensate for the ice hazard. Conditions are improving at this time of the year, so far as this feature is concerned, but who is to say what a belated spring may bring forward in those latitudes? In this connection it is of interest to consider a question that is frequently being put up to underwriters as to the liability of the latter for expenses incurred in transshipping cargoes at intermediate ports in event of the port of destination being closed by ice. These costs are not regarded by the underwriter as properly chargeable to him inasmuch as they are incurred by the shipowner in order to facilitate the turnaround of his vessel, and should be borne by the latter as part of the expense involved in earning his freight. The underwriter certainly continues on the risk until the discharge of the goods, and under the clauses of the policy granting the right to transship, and as respects deviation, he would seem to be liable for loss from an insured peril during transit, if the goods were transshipped at an intermediate port and forwarded to destination by rail. Phillips cites an interesting case of a vessel returning to her port of loading after being unable to enter her port of destination because of ice conditions. According to the decision in this case it appears that, if the master returned with the intention of ultimately completing the voyage when navigation opened, the underwriters would continue until the vessel had finally discharged her cargo at the port of destination. As a matter of fact, if the bill of lading required the owner of the goods to pay the expense of transshipment in such a case as that mentioned at the beginning of this paragraph, the underwriter might be willing to defray the cost in order to get off the risk that much sooner.

Salvage Charges Contested

CERTAIN salvage awards made by the Shipping Board are meeting with protest. A considerable number of underwriters feel that insurance interests are not fairly represented and that the salvage charges of the Shipping Board vessels are excessive and unreasonable. Under the salvage methods now employed by the Shipping Board their vessels are directed to proceed to the scene of an accident and to remain by, and this, it is felt, does not work out with fairness to the cargo interests involved. In event of an underwriter contesting a salvage charge in defense of cargo interests on a Shipping Board vessel, the final decision rests with a body that is not regarded as entirely unbiased because of its close identity with the Board.

Rates for Safety Appliances

WHEN promoters of safety devices for shipboard installation request a preferential in the premium rate for such appliances the underwriters generally reply that rates are predicated upon experience and that no credit can be given in the rate until the invention has proved its worth. This is because it is next to impossible to estimate the value of such inventions as far as the safety of a venture is concerned. It is probable that insurance rates have responded right along to the benefits derived from successful inventions that have increased the safety of voyages, as fast as these devices have shown by experience that they warranted it. Rates for ocean insurance have steadily gone down as shipbuilding has improved, and it has not always been because of the pressure of competition. Underwriting profits vary but slightly over a period of years, and the rates would not have come down had results not warranted it. Thus it is clear that added safeguards, minimizing the risks of the underwriters, have made rate reductions possible. Among such proven safeguards may be mentioned the wireless, the radio, numerous fire-fighting and fire-detecting devices, watertight compartments and similar improvements.

The "Model Bill" Becomes Law

MUCH to the gratification of all interested in seeing the way cleared for American marine underwriters to compete on more equal terms with their foreign competitors, the so-called "Model Bill" for the District of Columbia has passed Congress by a comfortable majority vote in both Senate and House and been signed by the President. The purpose of this legislation, as we have frequently pointed out, is to afford an example, or "model," for imitation in State Legislatures so that the handicaps imposed in the forty-eight political divisions of the country may be removed and American underwriters be given a fighting chance with their business rivals.

National Merchant Marine Association Convenes

President's Message Receives Unqualified Endorsement—Marine Subjects Discussed as a Non-Partisan Issue by Prominent Shipping Authorities

THE annual convention of the National Merchant Marine Association was opened by its president, Senator Joseph E. Ransdell, Friday morning, March 3, in the Rose Room of the Hotel Washington, Washington, D. C. The conventions of this association have come to be recognized as an annual forum for the discussion of matters affecting the merchant marine, and they have been attended by many of the leading representatives of the shipping industry. This particular convention, coming as it did only a few days after the President had delivered his message to Congress, and at what we believe to be practically the beginning of better times for shipping, was no exception to the rule.

Senator Ransdell declared in his opening address that patriotic motives alone and the desire and determination to wisely advise the President on matters relating to handling the colossal problems of American shipping had influenced the Shipping Board to seek light from the best possible sources. The board in reaching its conclusions on the facts and findings that were submitted to the President was assisted by eleven of the best known experts who were chosen regardless of their political belief.

Senator Ransdell then proceeded briefly to analyze the Administration Bill. He said that the subsidy was the essential feature and that, although the term "subsidy" had been an offensive term to the American people of both parties in the past, the situation is altogether different now. He declared that the proposed rebate of 5 percent on the income tax of the total amount of freight paid on exports and imports would reach "the cotton grower of the South, the grain grower of the West and the producer and manufacturer of every portion of the United States who exports his products abroad or imports anything from abroad."

Before introducing the Chairman of the Shipping Board as the next speaker, Senator Ransdell pledged himself, "as one member of the minority party in the United States Senate, to stand by the general principles enunciated in the President's message to Congress." This statement was received with great applause.

Chairman Lasker's Address

The study and recommendations upon which the President's message and the Shipping Bill are based represent "the enthusiastic and the unanimous view of the Shipping Board," said Mr. Lasker. "Senator Ransdell is to be congratulated on being the first man to publicly and favorably analyze the President's message but what would you do," he asked, "if you had prepared an address and the speaker preceding you had covered the same story that you intended to present?"

"The merchant marine is now a vital necessity if America is to live up to its destiny and it is the President's ambition to go into history as the Administration under which it was established," he said. "As to need of a merchant marine, from a naval standpoint there can be no divided opinion." The need exists and there can be no question as to the duty of our people to establish it in a time of peace.

"It is well known that, by and large, American ships cannot compete with foreign vessels unless Government aid insures that they will have to be sold or dismantled. I am one who holds that Section 34 of the Jones Act would have done more than any other aid that could have been given to establish our merchant marine but the President did not consider this in view of our international relations as being in the national interest.

Navigation Laws Not Taken Up

"It is not proposed at this time to change our navigation laws. This is a subject in itself, but I believe that I can speak with authority when I say that the spokesman of sea labor feels that there are certain much-complained-of provisions in our navigation laws which in due course should be modified.

"It is proposed that the board sell its ships at world prices so that the owners will not be burdened with capital charges exceeding those of foreigners. The board cannot meet the need for passenger ships but it is possessed of an ample fleet of cargo ships to meet any needs for years to come.

"We have asked Congress to give us a constructive loan fund of $125,000,000 as soon as possible to be loaned at not less than 2 percent interest for the construction of the modern types of vessels that we lack. This is provided for in the Jones Act at the rate of $25,000,000 a year for five years but we have asked that the entire sum be made available at once for shipowners to give work to American yards who sorely need it.

"Referring to the income tax provisions, I should like to make clear that 5 percent of all freight moneys that have been paid to American ships for either inbound or outbound cargoes shall be deductible from the income and corporation taxes. This provision is in lieu of the benefits that would have accrued to American shippers from Section 34 of the Jones Act. It will benefit all shippers and insure full cargoes for American ships.

Immigration

"It is proposed to secure at least 50 percent of the immigrant traffic for American vessels and, from such countries as do not possess a merchant marine, 100 percent. If this provision had been a law during the time that immigration was at its peak, we would not have been in the sorry plight that we were in 1914 when we had only 15 ocean-going passenger ships.

"The Naval Reserve will cost about $650,000 the first year and reach a maximum of $3,000,000 when 30,000 men will receive an annual retainer of one month's pay for their naval rating. This provision would be the greatest insurance against hasty and expensive naval training such as was entailed in our last war.

"Government officers going abroad on official business will be forced to travel on American ships when such are available or pay for their passage out of their own pocket.

"It is proposed in the law to discontinue the Army and Navy Transport Service and transfer their patronage to privately-owned vessels. I believe that if the real figures were available it could be proved that it can be done much cheaper in privately-owned ships.

To Bring Philippines Under Coastwise Laws

"The same objections that we heard against bringing Hawaii and Porto Rico under the coastwise laws are brought forward to show that the Philippines should not be made to come under these laws. Since Hawaii and Porto Rico have been brought under the coastwise laws they have prospered as they never prospered before. In fact, anything that is proposed to be done for American ships meets with the same kind of false propaganda.

"Preferential rail rates on through-shipments by American ships is now a law of the land. The Shipping Board is

making an intensive study as to whether the adequate facilities as required by the law are in existence and, if such facilities exist, the Shipping Board will direct their enforcement.

Subsidy

"The direct aid is based on a combination of speed, tonnage and distance covered. It will cost about $15,000,000 the first year and will reach $30,000,000 at the end of five years. I will not go into details about the rates of compensation proposed but by the use of the formula worked out we will get a balanced merchant marine of the types of ships needed to properly cover our trade routes. The funds are to be derived from 10 percent of the custom receipts and from doubling the present tonnage taxes. The ships receiving aid will not be paid for the carriage of the mails, excepting parcel post, but the sum due for this will be paid by the Post Office into the merchant marine fund and should amount to about $5,000,000.

A Check Against Profiteering

"In order that there could be no charge of profiteering, the proposed law contemplates that the direct aid shall follow the individual ship to the extent of 10 percent of its earnings in any one year. The earnings above 10 percent are to be equally divided between the Government and the shipowner until the subsidy has been repaid after which the ship keeps all its earnings. Where the indirect aids are sufficient, the direct aid would come back to the Treasury. It is an automatic check on itself.

"If in certain trade, such as Australia, the aid proposed should not be sufficient, the Shipping Board is authorized to increase it. If, however, the Shipping Board makes an error in the amount of aid it gives, automatically a check is on the error, because after 10 percent, half of the profits go back to the Treasury.

"Here is a definite remedial and creative proposal. If you don't want to accept it, what have you to offer? But don't bring up the genius of America for she has no greater genius for the sea than other nations. If ignorance, if selfish interest, or those who profit by the *status quo* are able to confuse the issue, the opportunity of the moment which peculiarly calls for action will pass."

Congressman Scott's Address

Representative Frank D. Scott of Michigan gave some idea of the importance of foreign trade when he stated that $4,000,000,000 worth of manufactured products should be shipped abroad annually, and also that 2 out of every 10 bushels of wheat must be exported. He claimed that the discontinuance of discriminatory duties in the last century killed our merchant marine and that the Seaman's Act was doing the same thing now.

He said the Seaman's Act affected the Great Lakes shipping much more severely than the ocean and that Great Lakes shipping cannot prosper until this difference is recognized. He asserted that not one of the passenger and cargo vessels on the lakes is now stopping at the islands or intermediate points.

Mr. Scott then took a shot at the Shipping Board by saying that it had been created as a first aid and then promoted to family physician. "Duplication is a great evil," he said, "the Shipping Board should be abolished and all its functions transferred to the Department of Commerce."

Demand for Passenger Accommodation

According to Mr. W. A. Harriman, who was the next speaker, a good indication of the demand for passenger accommodations is the number of inquiries that are received every day at the offices of the United American Lines for space on the new liners *Resolute* and *Reliance*. These vessels, which are the latest and most modern additions to the transatlantic passenger service, will be filled to maximum capacity during the coming season.

Mr. Harriman said that it was encouraging to know that the country was beginning to realize the importance of the work that the shipowners are doing and that this work could only be efficiently carried on by private interests.

Mr. Harriman pointed out the advantage that Great Britain had over us in the matter of ships of specialized design. He said that even in the cargo ship class they had vessels that could steam at 15 knots with which on certain berths our 10½-knot vessels could not successfully compete.

A Good Business Proposition

Commander Stevenson Taylor, president of the American Bureau of Shipping, declared that he knew of no better business proposition for the country at large than the wise expenditure of from thirty to fifty million dollars per annum so that our immense fleet of merchant ships can be operated profitably under private ownership. He said in part:

"Foreign shipping to us, after a lapse of over a century of inanition, is a new industry. It is now the one industry in the United States which needs protection by Governmental means more than any other. Every other of our great industries has had Governmental protection—a protection that has increased the cost of ships—and has a natural protection due to the geographical location of the United States, that is to say, the protection of at least 3,000 miles of water on both sides of this continent. Only three miles from our shores the ships of the world meet on an equality of opportunity.

"We cannot expect to maintain American standards of living on the seas, and compete successfully with ships operated under the lesser standards of our competitors. It then becomes necessary for our Government to see that American ships are given the same protection which our other basic industries have and should receive wherever economic conditions make it necessary.

"We must have our own delivery system, if we are successfully to sell our excess products in markets open to world competition, a delivery that will protect our shipments against delays and against damage caused, as has been asserted, either by wilfulness or carelessness. If we do not dispose of all our surplus products our national business will not continue to be successful. Hence, if we treat our shipping in the foreign trade solely as a delivery system, it is worth whatever it may cost, when we consider the business of the entire nation."

The Middle West Attitude

"Aside from the fact that we must maintain a fair-sized merchant marine in order to make our Navy effective, the Middle West looks upon the merchant marine as a means to an end," said Malcolm E. Stewart, chairman of the Middle West Merchant Marine Committee. He advocated the arrangement of conferences in the principal industrial and agricultural centers of the interior. In this way, the manufacturer, producer and business man can coordinate their interests to such an extent that each of them is bound to see the advantage of joining forces.

"Although the only way that we can get the kind of service best suited to expand our foreign trade is by building up an American merchant marine," he declared, "every convenience is offered to ship over foreign lines. The agents of the foreign shipper are ever bombarding the shipper with detailed information, making him familiar with the details of making shipments on every kind of a ship except an American, while the American steamship companies have not gone after this business with the proper spirit of cooperation and helpfulness."

Mr. Stewart said that the shippers of the United States

(*Continued on page* 244)

Fireboat John Purroy Mitchel

By I. C. G. Cooper*

The commissioning of the John Purroy Mitchel brings the number of fireboats comprising the marine division of the New York Fire Department to ten, or one vessel to every 58 miles of the city's waterfront. The enormous shipping activities carried on in the port of New York place a heavy responsibility upon this branch of the Fire Department and the rare occasions of loss or damage by fire are due to the thoroughness with which it works.

THE latest addition to the floating fire-fighting equipment of the New York Fire Department is the up-to-date vessel recently built and delivered by the Standard Shipbuilding Corporation at Shooters Island, N. Y.

The *John Purroy Mitchel* is a notable example of modern fireboat design. The particulars of the vessel are as follows:

General Information

Service: Fireboat for New York Harbor.
Builder: Standard Shipbuilding Corp., Shooters Island, New York.
Owner: Fire Department, City of New York.

Characteristics

Length, overall	133′-7½″
Length, B. P.	121′-0″
Breadth, molded	27′-0″
Depth, molded	14′-9″
Draft, loaded	9′-6″
Draft, light	
Block coefficient	0.58
Midship section coefficient	0.95
Longitudinal coefficient	0.61
Speed, loaded, knots	10.5
Cruising radius, nautical miles	
Framing	Transverse
Class	American Bureau of Shipping

Tonnages

(In tons of 2,240 pounds.)

*Weight of Hull	207
**Weight Propelling Machinery	180
Deadweight Capacity	
Displacement	476

(In tons of 100 cubic feet.)

Gross register	334.75
Net register	227.63

* Weight of Hull includes Hull Proper, Hull Fittings, Equipment, and Outfit.
** Weight of Propelling Machinery includes Engines, Boilers (Wet), Shafting, Propellers, Machinery Space Auxiliaries, Fire Pumps and Pipe System.

Equipment

Anchors, (1) stockless	350 lbs.
Chain, ⅝″ galvanized B.B.B.	20 fms
(10) Fenders, oak with manila lanyards	

Rudder

Area, square feet	52.6
Dia. Stock, inches	6

Deck Machinery

Steering Gear, Hyde	5½″x5½″
Capstans, (1) Hyde	4½″x6″

Life Saving Equipment

	No.	Type	Length
Lifeboats	1		12′-0″
Liferaft	1		7′-4″x4′-0″

Propelling Machinery

Boilers

Number	2
Type	B. & W, watertube
Length	9′-0″
Width	9′-8″
Furnaces, per boiler	3
Fuel	oil
Draft	forced
Total heating surface, square feet	4,840
Working pressure, lbs. per sq. in.	200

Engines

Number	1
Type	Reciprocating
Size	18″x38″x26″ stroke
Horsepower, indicated	720

Propellers

Number	1
Type	R. H., 4 bladed, semi-steel
Weight, tons	1.61
Diameter	8′-8″
Pitch	10′-6″
R. P. M.	140
Projected area, sq. ft.	22 6
Developed area, sq. ft.	28.0

Auxiliary Machinery

Machinery Space

Condensers (1)	2,500 sq. ft. cooling surface
Feed water heater	1
Fuel oil heater, Coen type	6 section

Pumps:

(2) Oil fuel	6x4x6
(1) Air	9x18x9x18x12
(1) Main feed	9x6x10
(1) Donkey	9x6x10
(1) Circulating	12″ centrifugal
(1) Fresh water	4½x2¾x4
(1) Sanitary	4½x2¾x4

(2) Turbo driven fire rotary type.

Electric Equipment

Generator, (1)	10 k.w. 110 volts, 91 amperes
Radio	
Emergency	

Bunkers

Compartment	Cu. Ft.	*Tons
F. O. tank, port	870	22.3
F. O. tank, star	720	18.4
Total	1,590	40.7

*39 cu. ft. per ton.................gals. per bbl.

Tanks

Compartment	Cu. Ft.	Tons F. W.	Tons S. W.
F. W. forward	1,200	33.3	..
F. W. aft	480	13.3	..
Total	1,680	46.6	..

Hull

The hull is built to meet the requirements of the American Bureau of Shipping and is further strengthened to withstand the possibility of work in ice, in the extensive waterways around the city, by closely spaced frames forward, additional breast hooks and thickened bow plating.

Two sturdy oak fenders extend along the sides. The upper, 10 inches by 10 inches, extends completely round the vessel at the level of the main deck and the lower, 8 inches by 8 inches, located 2 feet above the waterline, extends from the fore end aft for four-fifths the length. Each fender is faced with 6-inch by ¾-inch flat steel bars.

Angle bar framing is used with solid floors and reverse bars extending 18 inches above the top of the floor plates. The reverse bars are double in the engine room and on alternate frames in the boiler room. Beams are fitted on alternate frames.

The single deck has substantial stringers and tie plates and is sheathed with 3-inch Oregon pine 3½ inches wide with a 7-inch yellow pine margin.

A feature of the vessel is the spacious nature of this deck, allowing easy access to the various fire turrets and hose reels and permitting free action for the firemen at every point.

Spacious quarters are provided for firemen and officers forward and for engineers aft. Berths are of the single spring type with lockers underneath. A washroom for stokers is directly accessible from the stokehold through a passage, fitted with airtight doors at each end, which also forms the swash bulkhead of the oil fuel tank.

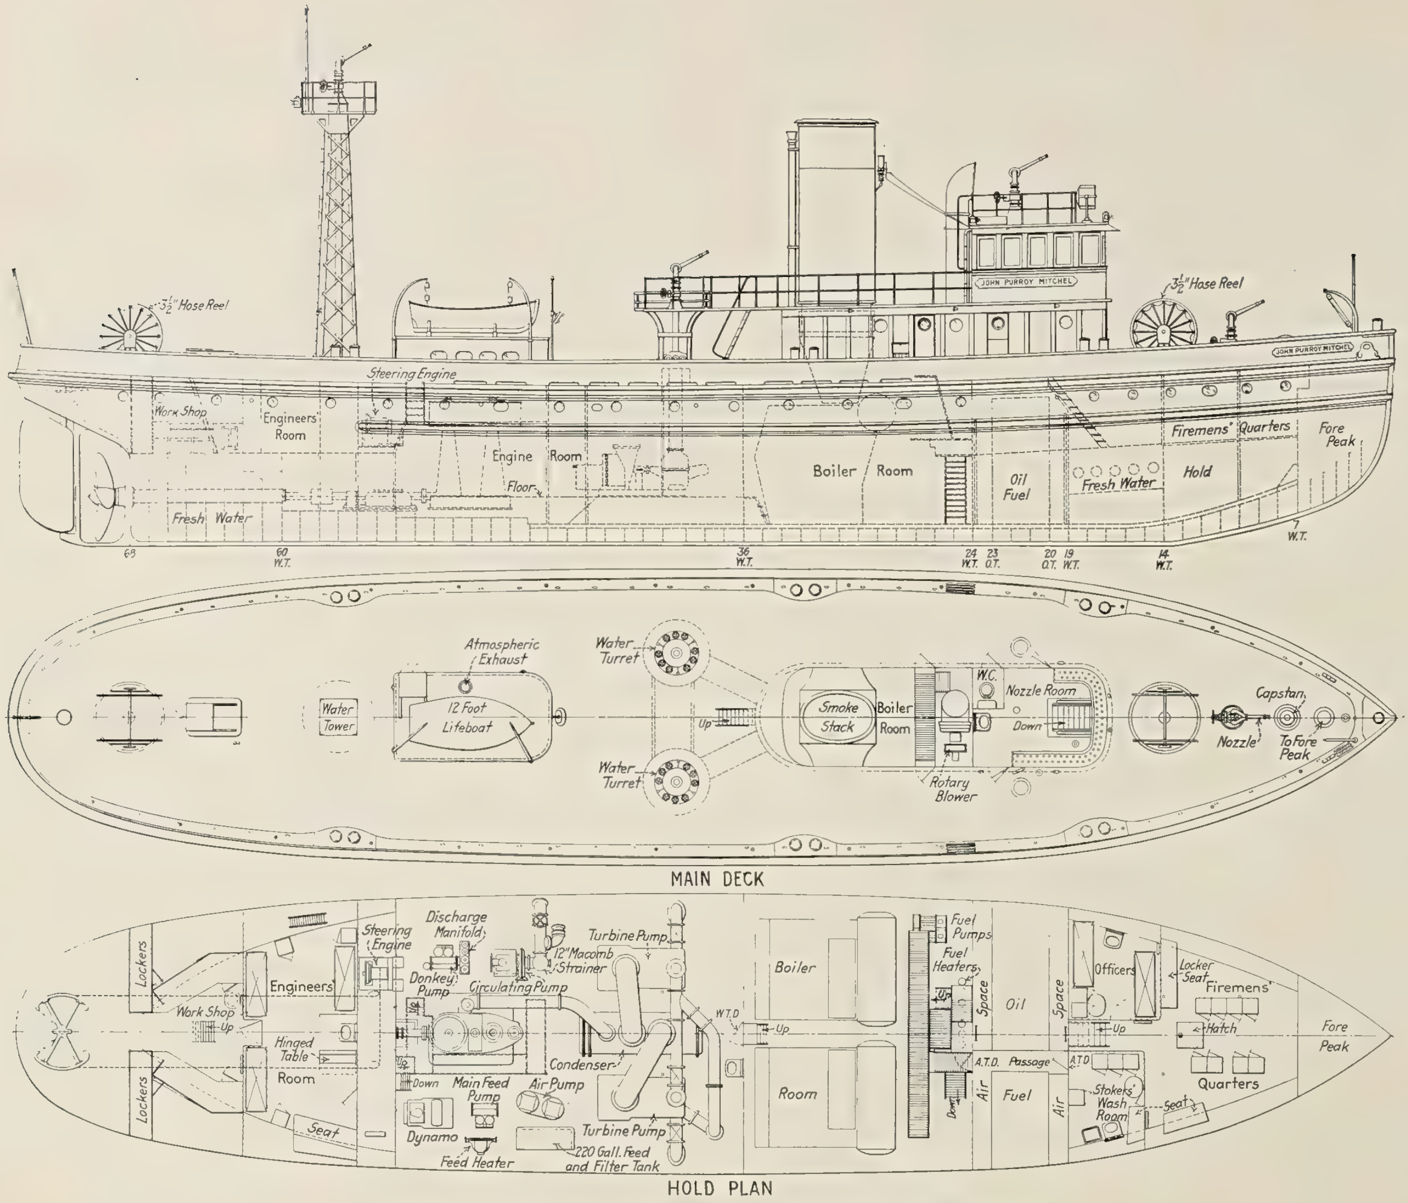
A well lighted workshop aft is fitted with two large benches and has ample locker and shelf stowage.

The entrance to the forward quarters, under the pilot house, is utilized as a nozzle room.

Main Propelling Machinery

The main engine is of the reciprocating, surface condensing type consisting of high pressure and low pressure cylinders with balanced cranks placed at right angles. All desirable

*Assistant to the naval architect, Standard Shipbuilding Corporation.



Profile and Deck Plans of Fireboat John Purroy Mitchel

auxiliaries have been fitted as shown in the table of particulars.

Boilers

The boilers are of the Babcock and Wilcox watertube type with large straight tubes designed for 200 pounds pressure and equipped for burning oil fuel on the system supplied by the Babcock and Wilcox Company at Bayonne, N. J.

The total capacity of the boilers is 29,000 pounds of dry steam per hour when working in a closed stokehold under a supply of 18,000 cubic feet of air at 1½ inches pressure. The air pressure is maintained by a rotary blower placed in the fireroom entrance at the main deck level, drawing from a 26-inch diameter geared cowl and delivering directly into the fireroom.

Oil fuel is stored in a special bunker, forward of the boiler room, protected by air spaces at the ends and on top.

The deck over the boilers is protected by 3/16-inch asbestos millboard laid over a complete sheathing of 6-pound plating.

Fire-fighting Equipment

A feature of the vessel is the completeness and power of her fire-fighting equipment. Water is delivered by rotary pumps, turbine driven, having a total capacity of 7,200 gallons of salt water per minute at a pressure of 175 pounds, or 9,000 gallons at a pressure of 150 pounds per square inch. The power is provided by two impulse type turbines developing 600 brake horsepower at 2,000 revolutions per minute under steam pressure of 200 pounds and exhausting into a condenser with 26-inch vacuum. The pumps are also cross connected so as to provide together a delivery of 4,500 gallons at 300 pounds pressure. The water is distributed through five large swivel nozzles mounted on the pilot house, after tower and forward deck and also through two midship turrets, each having 9 connections for hose.

Swivel play pipe holders are fitted at regular intervals in the 12-inch by 4-inch oak rail on the bulwark which is heavily constructed for this purpose.

Two reels on turntables, one forward and one aft, afford stowage for 1,000 feet of 3½ inch hose and two others are to be supplied which will stow 1,000 feet of 2½ inch hose and 1,000 feet of 1½ inch hose, respectively.

The substantial and workmanlike finish of the hull, machinery and fitting of the vessel, together with the up-to-date nature of the pumps make this a valuable addition to the city's fire-fighting force and will admit of a better distribution of the fireboats now in commission.

Trials

The boilers on trial were found capable of a much higher

evaporation than the contract called for. At one trial 35,000 pounds of steam were produced per hour against the specified 29,000 pounds.

Satisfactory results were also obtained with the turbine pumps.

The final full power speed trials were carried out on the Hudson River mile on November 9, 1921, in rather rough weather. Six runs were made with the following results:

Run No.		Speed in Miles	Propeller Revolutions per Minute
1	Against wind and tide....	13.28	160
2	With " " "	15.31	160
3	Against " " "	13.13	150
4	With " " "	15.42	150
5	Against " " "	13.33	150
6	With " " "	15.72	150

The mean speed was 14.3 miles per hour, and at 140 revolutions the speed was 13.75 miles per hour. Complete circles were turned both to port and to starboard in 2 minutes 12 seconds.

At 150 revolutions it took 24 seconds to completely stop the vessel when the engines were reversed.

The vessel was designed by Messrs. J. W. Millard & Brother, naval architects, 17 State street, New York, and the details were developed by the builder's drafting staff under the direction of Mr. Peter Mitchell, naval architect. Mr. F. Thompson, assisted by Mr. J. Woods, represented the Fire Department during construction.

Organization of Marine Division, New York Fire Department

There are now ten fireboats comprising the marine division of the New York Fire Department and each boat has a certain area that it covers on a first alarm. Two boats usually respond at each waterfront fire and if, during the absence of either of these boats, a second fire occurs, the boat from the adjoining district will respond. At least one boat responds to every waterfront fire. It is also possible to concentrate all boats at any particular point by means of a special signal.

An added duty and service of the fireboat fleet is to supply the high pressure mains in lower Manhattan and Brooklyn with salt water in an emergency. They can also be used to relay water to land engines operating a great distance from the waterfront, if for any cause the water supply has failed.

At a very serious fire the auxiliary fireboats, consisting of the tug boats of the various railroad companies, oil companies, steamship companies, etc., are called by a special signal to the Fire Department dispatcher at headquarters. These auxiliary fireboats are all equipped with pumps and have in the past performed effective work at fires.

The waters about the city of New York are at present divided for fireboat operation into districts as follows:

New York Harbor from Scotland lightship to buoy off Rockaway Point, Jamaica Bay, Staten Island Sound, Hudson River to Yonkers, East River including Gowanus Canal, Wallabout, Bushwick and Newtown Creeks, Harlem River, Long Island Sound, bays and tributaries to Sands Point.

The fireboats covering these districts are:

Name	Station	Length	Capacity in Gals. per Min.
The New Yorker	Battery	136'6"	12,000
Wm. L. Strong	Grand St., East River	110'0"	6,000
Zophar Mills	Beekman St., East River	120'5"	6,000
George B. McClellan	99th St., East River	117'0"	7,000
James Duane	35th St., North River	131'0"	9,000
Thomas Willett	Bloomfield St., North River	131'0"	9,000
Cornelius W. Lawrence	135th St., Harlem River	104'6"	7,000
Wm. J. Gaynor	37th St., South Brooklyn	118'0"	7,000
Abram S. Hewitt	Foot of Noble St., Brooklyn	117'0"	7,000
John Purroy Mitchel	Not assigned	132'0°	9,000

In addition to their duties about the city of New York, these fireboats have on numerous occasions rendered aid to cities and towns along the New Jersey shore.

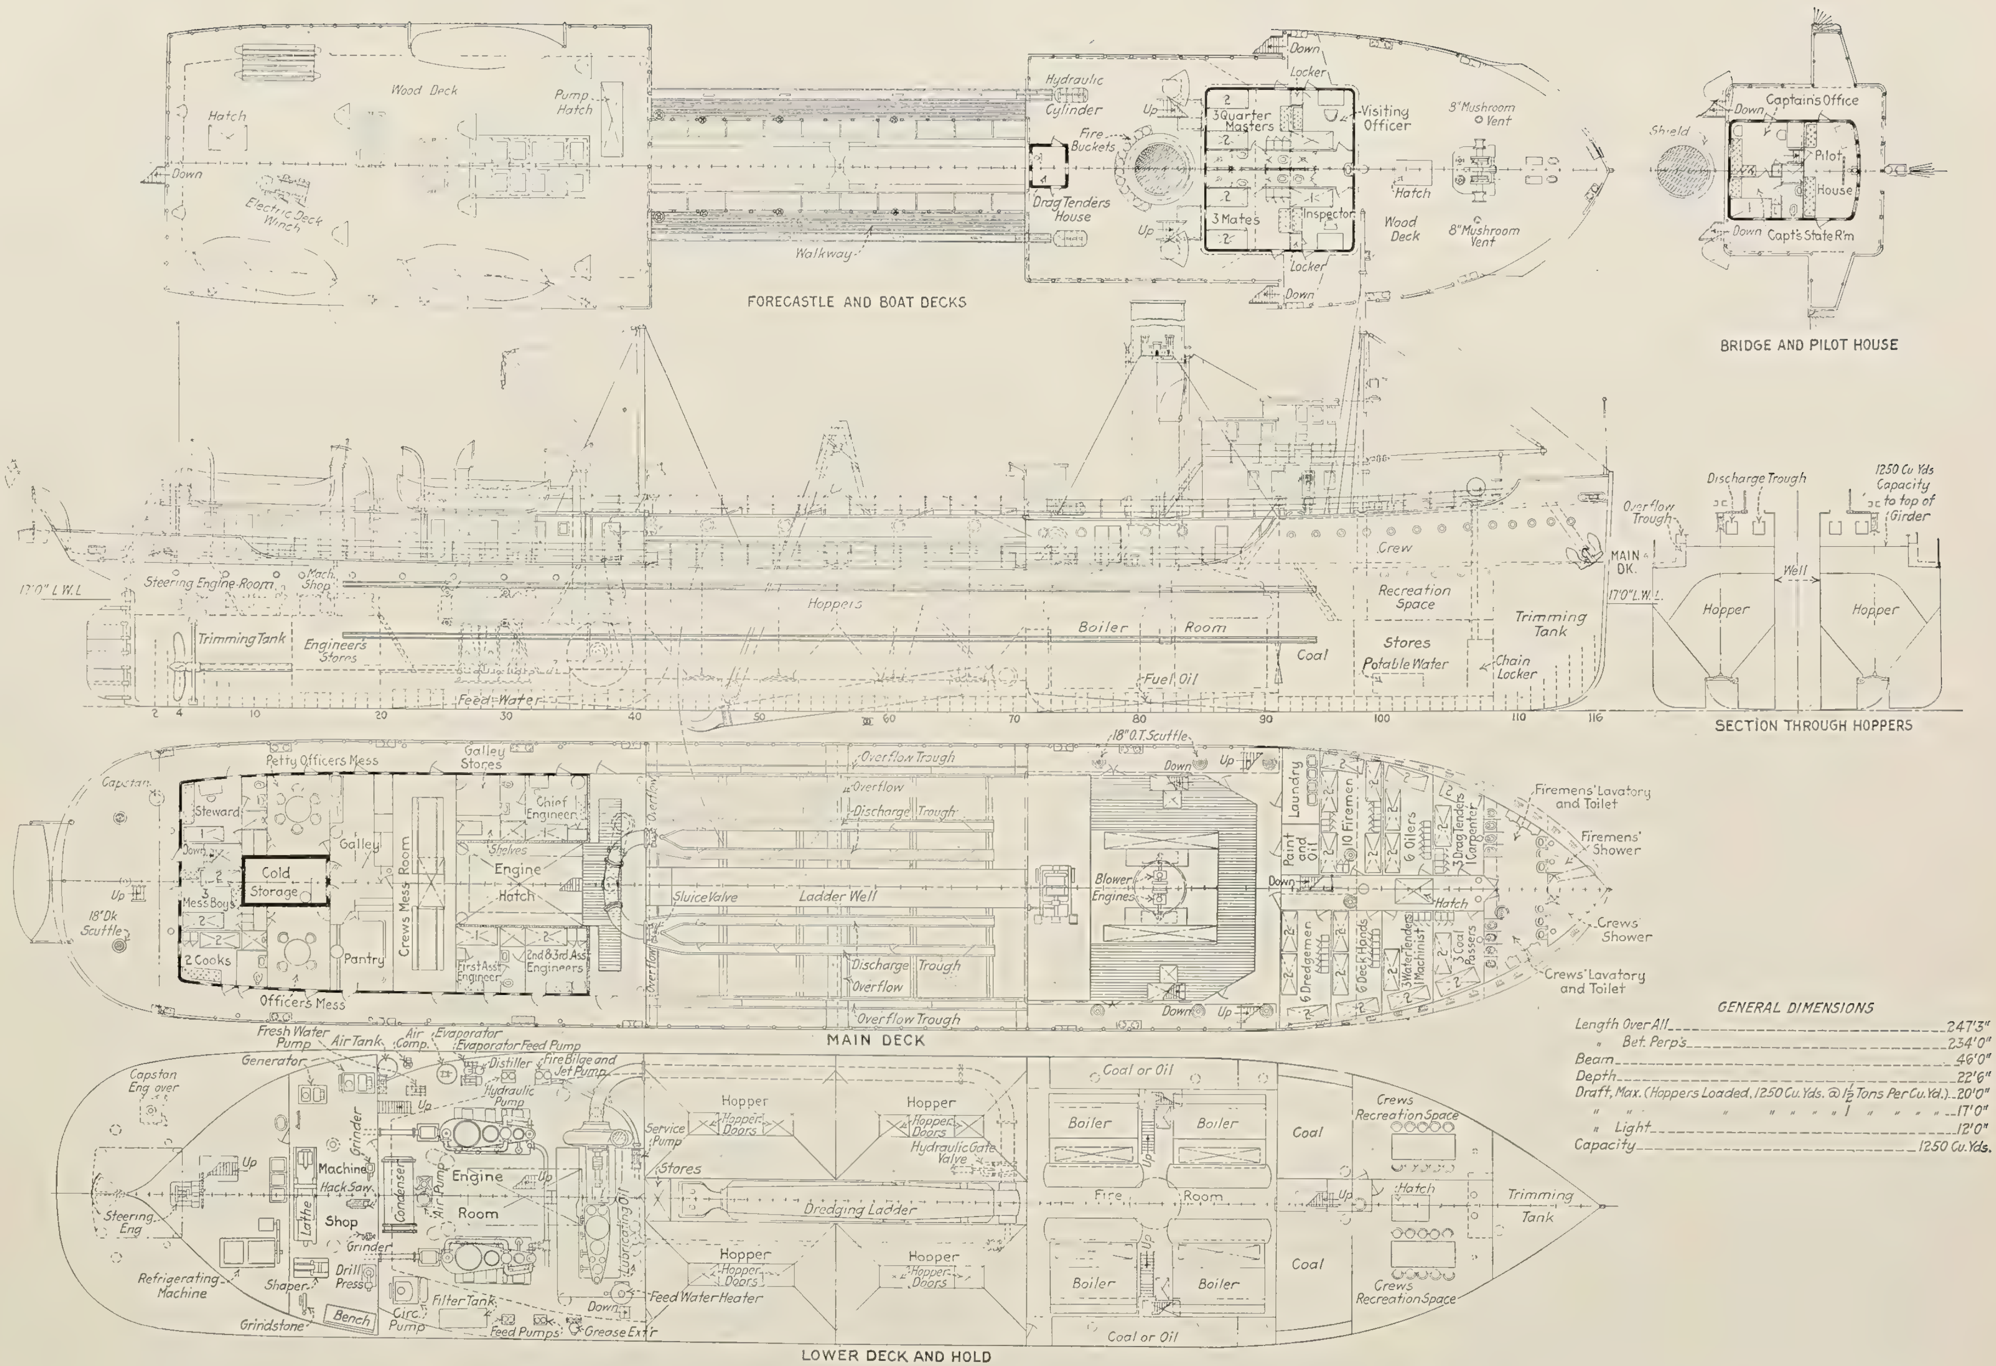
Oxy-Acetylene in China

THAT China, a country whose worship of antiquity has retarded its own development and progress until comparatively recently, is at last awakening to ideas and activities of the fast moving world beyond her domains is evident in many ways. One of these that is typical of her newfound modernism is the adoption of oxy-acetylene welding and cutting.

Welded Section of Rudder Frame

Welded Stern Post

The photographs reproduced herewith were secured through the courtesy of the Export Department of the Oxweld Acetylene Company. They show interesting work done by the Oxy-Acetylene Welding Works, at Shanghai. A rudder frame of the French S. S. *Cordillere* was broken, and the ruptured section (9 inches by 5 inches) was repaired by welding in four hours. The location of the weld is shown by crossed chalk lines in the photograph at the left. Another weld (on the stern post) is indicated by the arrow in the picture on the right. The work was done by Chinese labor.



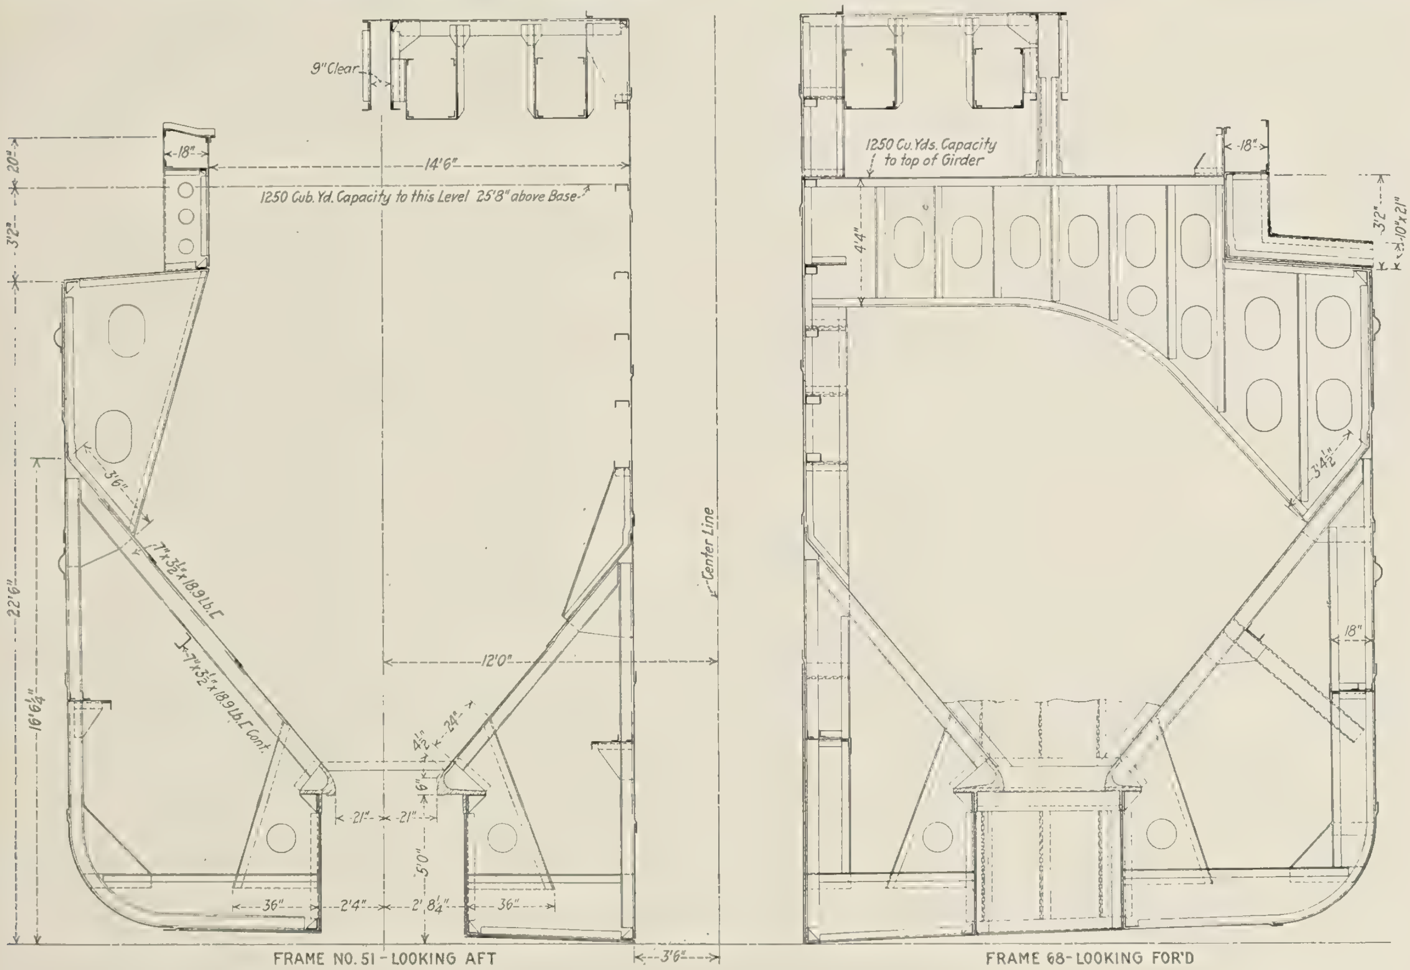
General Arrangement Plans of Sea-Going Hopper Dredge of 1,250 Cubic Yards Capacity

Sea-Going Dredge of 1250 Cubic Yards Capacity

Latest Design of Hopper Dredge for Use by the United States Engineer Department on Bar Dredging

By Theodore R. Vogel* and L. D. Norsworthy†

THE following description of the seagoing hopper dredge recently designed, under the direction of Brigadier General Harry Taylor, in the Marine Design Division of the Office of the Chief of Engineers, War Department, brings out many points of improvement over the former design of a similar type. The design follows very closely that of the *Col. P. S. Michie* which has the drag located in a well at the center of the hull and which was designed in the Office of the Chief of Engineers about ten years ago.



Transverse Sections Through Hoppers

The *Col. P. S. Michie* was designed primarily for use at Coos Bay, Oregon, where the severe weather conditions encountered made a specially designed dredge necessary for successful operation. This dredge has been in continuous operation since its construction in 1914 and has proved itself so superior to all other types that at a conference, held in the Office of the Chief of Engineers in February, 1920, it was agreed that future designs should be of the center well type with such improvements as have been developed since the *Col. P. S. Michie* was designed.

Criticisms of the hopper dredges in the various Engineer Districts of the War Department were received from the United States Engineers in charge of the districts with suggestions for their improvement. These criticisms were carefully analyzed and the following general principles established for the future design and operation of dredges:

(a) That a dredge is an expensive craft and economy is attained only when it is kept at work the greatest possible time throughout the year.

(b) That dredges of small capacity are uneconomical in operation as not enough space is available for a crew sufficient to operate the dredge twenty-four hours a day.

(c) That the machinery must be of the most efficient type and of such rugged construction that it will stand up under almost continual use, with the amount of time required for repairs, renewals, etc., reduced to a minimum.

In deciding to design a dredge of the center well rather than the stern well or side drag types, the following advantages of the former over the latter two types were considered:

The weight of the drag arm acts somewhat as a centerboard and thus tends to steady the dredge in rough weather. Further, after the drag has been lowered it remains on the bottom and at work practically all the time. This is a decided advantage over the side drag type where the drags

are continually lifted from the bottom due to the roll of the vessel, and also, if there is a cross current or cross wind, the offside drag has to be constantly lifted to prevent the dredge from sitting on and breaking the drag pipe. In regard to the stern well type the inherent disadvantage is that it will not steer well due to the heavy drag at the stern acting as an anchor. With the drag in a center well it is almost under the turning point of the vessel so that the dredge in steering practically uses the drag as a pivot on which to turn. Size for size the center and stern well types are both at a disadvantage when compared to the side drag type due to loss of buoyancy in the wells. This, however, is not considered serious as the increase in draft is comparatively slight. Then again the hull has the appearance of a commercial vessel with clear sides and has not the difficulty in lying at a wharf or making a landing that a dredge with drags, drag pipes, sponsons and davits on the sides does.

It was agreed that two sizes would be designed, one of 1,250 cubic yards capacity and one of 2,500 cubic yards capacity; the first dredge to have a load draft of 17 feet, with material in hoppers weighing one ton per cubic yard, and be of sufficient depth to give a freeboard of 2 feet 6 inches when loaded with material in the hoppers weighing 1½ tons per cubic yard; the second dredge to have a load draft of 20 feet with material in the hoppers weighing one ton per cubic yard and be of sufficient depth to give a freeboard of three feet with material weighing 1½ tons per cubic yard in the hoppers.

So far only tentative plans have been made for the second dredge.

Improvements Over Previous Designs

The points considered improvements over previous designs are as follows:

(1). Continuous main deck.
(2). Location of all quarters above the main deck.
(3). Provision for recreation space for the crew.

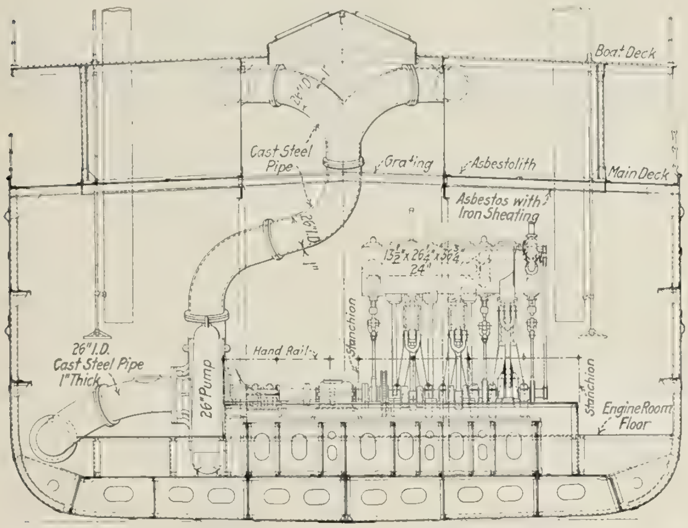
(4). Provision for sufficient quarters for three shifts of crew.

(5.) The elevation of hopper doors so that when opened they will not project below bottom of vessel. (This arrangement will allow the hoppers to unload should the dredge ground.)

(6). Omission of hips between the doors in each hopper.

(7). Replacement of hopper door chains with rods and the use of cast steel for the hopper doors and frames.

(8). Provision for dumping hoppers singly.



Transverse Section at Frame 35, Looking Forward, Showing Dredging Pump and Engine

(9). Provision for a 20-inch water cushion at the top of the hopper.

(10). Provision for a double discharge trough over each set of hoppers so that the discharge streams will oppose each other, tending to quiet the water and allow a better settlement of the dredged material.

(11). Overflow troughs from hoppers located outside of hoppers with discharge above deck.

(12). Increased length of dredge arm for dredging to a depth of 45 feet with arm at an angle of 43 degrees to the horizontal.

(13). Underside of dredging ladder fitted with plate so that center well is practically closed at bottom when ladder is in a horizontal position, thereby reducing eddy formation and increasing speed when dredge is under way.

(14). Lighter and narrower drag head.

(15). Water jets for drag, for use in dredging stiff material.

(16). Location of the drag operator's house and drag hoisting machine at forward end of hoppers so that the operator has a clear view of the discharges and the drag lines at all times and to increase the length of the leads from the drag hoist frame.

(17). Passageway from engine room to boiler room.

(18). Provision for greater accessibility to dredging pump.

(19). Provision for lifting dredging pump directly out of engine room.

(20). Installation of a dredging pump having a larger suction mouth and easier stream lines into the impeller.

(21). Increase in power of propelling engines to 900 indicated horsepower each.

(22). Triple expansion propelling engines.

(23). Installation of propellers with detachable blades.

(24). Outboard shaft protection device provided.

(25). Increased boiler capacity so that any three of the four boilers will furnish sufficient steam for maximum operation.

(26). Installation of steam superheaters.

(27). Installation of evaporator plant.

(28). Increase of fuel and water supply to provide for one week's operation.

(29). Provision for carrying either fuel oil or coal.

(30). Telemotor control for steering engine.

(31). Provision for hand steering.

The changes outlined above necessitated increasing the length 5 feet, breadth 3 feet and the depth 2 feet 6 inches over similar dimensions of the *Col. P. S. Michie.*

When the dredge is handling heavy material an additional 100 cubic yards can be carried in the hopper by eliminating the water cushion.

Operation

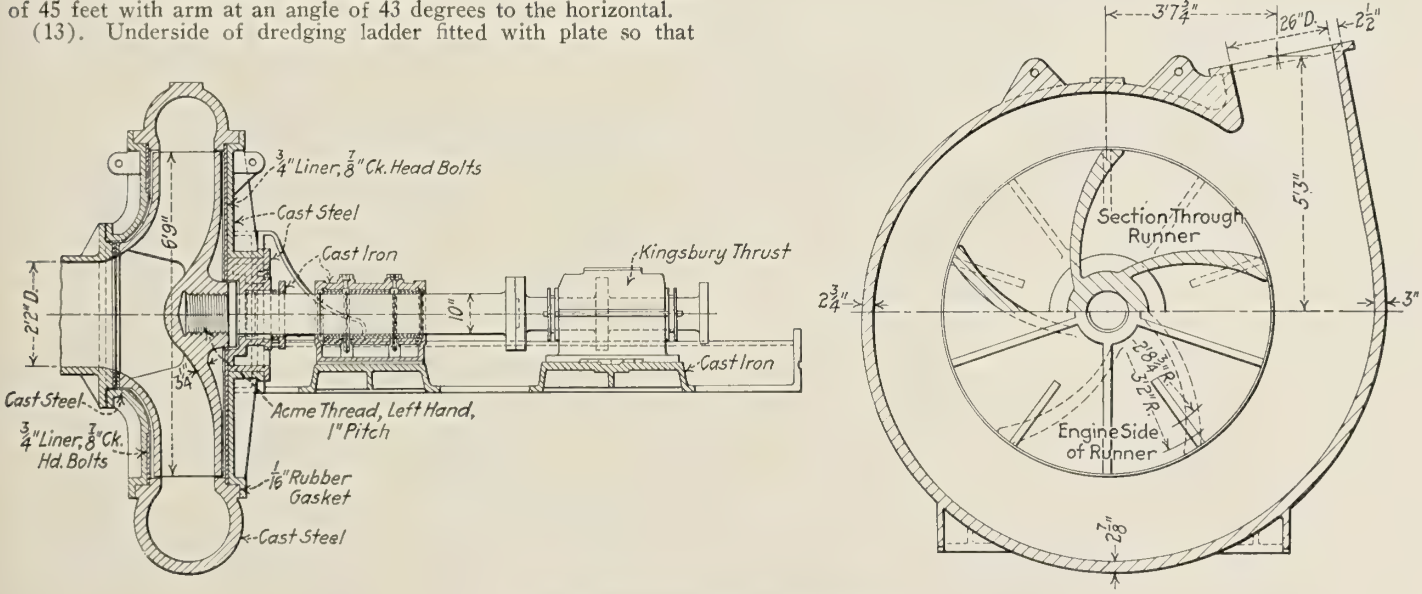
In operating, the dredge is kept moving forward at a speed of from one to two miles per hour with the drag down. The material is sucked up through a grid in the suction head, passes up through a 26-inch pipe in the drag arm to the trunnion, thence aft to the dredging pump. Just above the pump a "Y" pipe is fitted leading to double discharge troughs on each side of the well. These discharge troughs empty through adjustable doors into four large hoppers, each hopper having a pair of gates at its bottom.

Each hopper is fitted with an outboard and end weir, arranged to permit waste water to overflow into troughs which discharge overboard across the main deck.

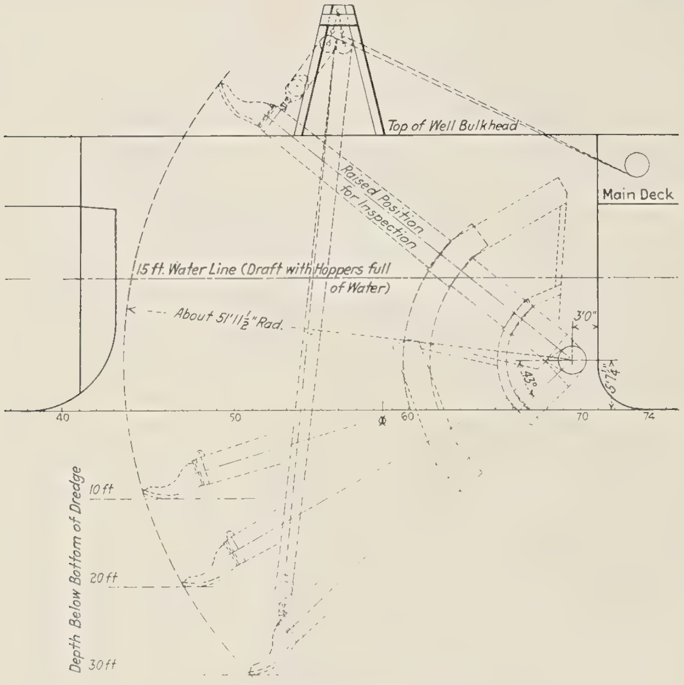
The hoppers and machinery have been so located that the dredge will trim practically on an even keel with no load or full load in hoppers, which allows an even flow of water into the overflow troughs. When the hoppers are full the dredge proceeds to the dumping ground, where the material is deposited by opening the hopper gates.

The drag arm, which contains a 26-inch suction pipe, is connected to the hull by means of heavy cast steel trunnions and is raised and lowered by means of wire rope falls.

Accommodations are provided for three shifts of crew to permit continuous operation of the dredge.



Details of 26-Inch Dredging Pump



Dredging Depth Diagram

The crew, firemen, oilers, etc., are berthed forward in commodious quarters in the raised forecastle.

Recreation rooms are provided on the lower deck forward where those off duty may lounge or read.

The engineers are berthed in quarters near the engine room and the deck officers in an upper deck house forward.

The captain's stateroom and office are located immediately aft of the pilot house.

Propelling Machinery and Boilers

The propelling engines, of which there are two, are of the triple expansion type capable of developing 900 indicated horsepower each at 100 revolutions per minute.

Four watertube boilers are provided of such capacity that any three will provide sufficient steam for maximum operations. By this arrangement, boiler cleaning can be done while the dredge is operating, thus avoiding the need of laying up for this purpose during the time when dredging can be done or the necessity of Sunday cleaning.

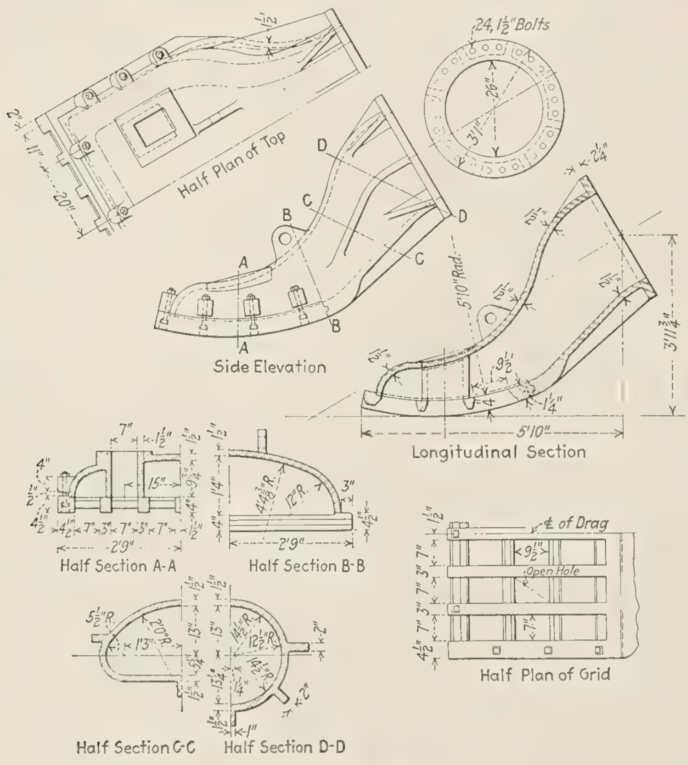
The boilers are placed forward of the hoppers so that their weight will counterbalance that of the machinery and keep the dredge on an even keel with no load or full load.

A passageway has been provided under the hoppers for communication between the engine and boiler rooms. This passageway also provides an additional escape from the fire room.

To compensate for the drop in steam pressure, due to the long steam pipe from the boilers to the engines, and as a source of economy in fuel consumption, steam superheaters have been provided to deliver steam with 50 degrees of superheat at the engines.

While the boilers are to burn oil primarily, provision has been made for changing to coal burning with a minimum of trouble, expense and time.

Induced draft blowers have been provided so that, in the event of coal being used for fuel, sufficient evaporation will be obtained from three boilers, the same as for oil, for maximum operation.



Drag Head Castings

Dredging Machinery

The pumping engine is of the triple expansion type direct connected, through a Kingsbury thrust, to the dredging pump and operates at 145 revolutions per minute.

The dredging pump is of the volute type having a 26-inch suction and discharge.

All bends in the suction and discharge pipes are given as large radii as practicable to reduce friction losses to a minimum.

The drag is of the flat face type with grids to limit the size of dredged material that may enter. The sum of the areas of the openings in the grid is equal to twice the area of cross section of the 26-inch suction pipe.

A water pressure system has been provided for supplying water under pressure to jets in a special drag for dredging in clay or hard packed sand. These water jets agitate or loosen the clay or sand for dredging.

The remarkable record of the *Col. P. S. Michie* has created a great deal of interest in this type of dredge and the Government has received a number of inquiries for detailed information regarding the latest designs from persons who follow up this line of work both here and abroad.

Plan for Cooperation Between Shippers and Shipping Board

Chairman Lasker and Vice-President Love, on March 4, met the committee appointed by the Middle West Merchant Marine Association, representing the chambers of commerce of twenty-five of the largest cities in the Middle West, headed by Malcolm Stewart of the Cincinnati Chamber of Commerce, to receive a report of the committee outlining the best form, in their opinion, of cooperation between shippers in the interior and the United States Shipping Board.

It has long been the desire of Chairman Lasker and Vice-President Love to bring about a closer working understanding between American shipowners and operators on the one hand and exporters throughout the country on the other, and plans had already been laid to this end. The intervening period has been used in order to so improve Shipping Board services as to enable its representatives to offer to exporters of this country services equal to, if not superior, to those maintained by the flags of other nations. In doing this, some eighty lines required consideration.

Motorship Dominion Miller, Built for the Furness, Withy Line and Fitted with One 3,000 Horsepower Doxford Oil Engine

3,000 Horsepower Single Screw Motorship

Doxford Engined Vessel of 9,400 Tons Deadweight Built for Furness, Withy and Company—Boiler Oil Proposed as Fuel

By Our Special London Correspondent

AT the end of February, trials were run of one of the most interesting motor vessels that has yet been completed, particularly notable in that it represents the largest type of motorship in which single screw machinery is installed.

With the increasing confidence now felt in the internal combustion plant, shipowners are asking that the normal twin screw arrangement which has been adopted, to a certain extent as a safeguard, should be abandoned and that the cheapness, simplicity, convenience and higher efficiency of single screw craft should now be gained. It is for this reason that some well known oil engine manufacturers such as Burmeister and Wain have developed a special type of Diesel motor suitable for installation in a single screw craft, the main difference from the normal design being that a longer stroke is employed and naturally a lower speed of rotation.

The First Furness, Withy Motorship

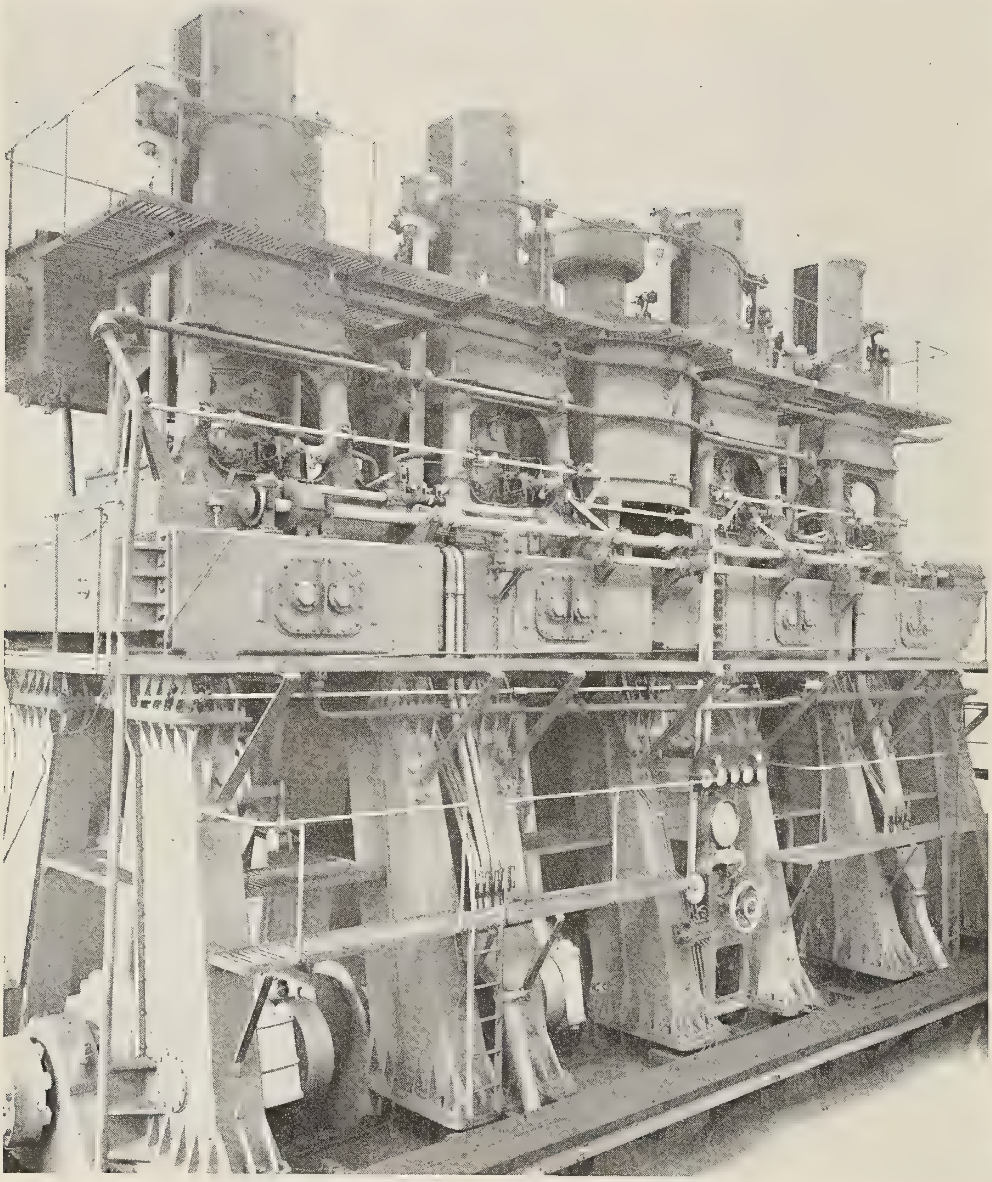
The Doxford opposed piston oil engine is intended essentially for single screw ships and incidentally is the highest powered internal combustion marine engine that has ever been built commercially. The vessel which was recently completed, the *Dominion Miller,* built for Furness, Withy and Company, is equipped with one of these Doxford engines and is in many respects similar to the Transatlantic Steamship Company's motorship *Yngaren* which has now been in service for two or three months. Incidentally the *Dominion Miller* is the first vessel built for Furness, Withy and Company and it is understood that this large concern —one of the biggest in Europe—will probably adopt a policy of motorship construction, should the results of this venture prove successful.

There are other features of special interest in this ship both for engineers and shipowners. Controversy rages around the question, whether what is known as boiler oil is suitable for use in internal combustion engines or whether it is desirable that only the higher grade and lighter Diesel fuel should be utilized. Manufacturers of two stroke engines claim that, with the absence of exhaust valves, boiler oil may be employed with complete immunity from trouble but up till the present time no European ship has run more than a few hours on end on boiler oil.

Seven-Day Test of Doxford Engine Using Boiler Oil

In order to satisfy themselves on this point, Doxfords recently ran a trial of 7 days' duration, during the whole of which Mexican boiler oil of a specific gravity of 0.95 was burned. According to the reports that have been published, the results were eminently satisfactory; the fuel consumption was equal to that attained on Diesel oil and, when the engine was opened out, it was in a perfectly clean condition.

On the strength of this, therefore, the owners have decided that after operating for a short time on Diesel oil in order to make quite sure that the engine is mechanically perfect, they will then run the machinery on a mixture of boiler and Diesel oil, and finally use only the former fuel. The experiment will be watched with the greatest interest since in many ports there is a very considerable difference in the price of boiler and Diesel oil, the former in England costing £3.15.0 and the latter £5.15.0 per ton.



3,000 Indicated Horsepower Doxford Opposed Piston Engine

dentally is the lowest speed that has yet been adopted in any marine Diesel engine. There are only four cylinders so that the output per cylinder is 750 indicated horsepower and as the brake power of the motor is 2,700, each specific cylinder output is 675 brake horsepower—easily the largest that has yet been attained.

The cylinders are only 580 millimeters diameter, which is much less than that of the biggest Burmeister and Wain eight cylinder 3,200 indicated horsepower engines and gives some indication of the possible advantage of the two stroke type. The stroke of each piston is 1,160 millimeters, giving a total effective stroke of the two opposed pistons combined of 2,330 millimeters.

The principle of the operation of the Doxford opposed piston engine is now fairly well known. The bottom piston drives direct on to a crank on the crankshaft and the crosshead of the upper piston is attached to two vertical rods joined at their bottom ends to connecting rods driving on to cranks, one on each side of the main cranks. There are thus, in all, thirteen cranks, including that driving the scavenging pump, and the difficulty of constructing the crankshaft is perhaps one of the chief points that has been urged against the Doxford engine.

The long stroke of the piston necessitates a liner over 10 feet in length and here again the greatest care in construction has to be exercised since this liner is pierced in the center for the reception of two fuel valves, one at the back and one at the front, in addition to the starting air and relief valves. The liner is ribbed, crosswise and vertically, for about a third of the length at the center and it is held at this point by the cylinder barrels, the remaining portion of the liner being free to expand. The scavenging ports are at the bottom of the liner and the exhaust ports at the top, the only mechanically operated valves being the two fuel valves for each cylinder and the starting air valves.

What is known as solid injection of fuel is employed in this engine, a battery of fuel pumps being driven from the crankshaft supplying fuel to the valves at a pressure of no less than 9,000 pounds per square inch. An auxiliary set of fuel pumps is installed in the engine room and this, like the other plant, is driven by means of a steam engine. Scavenging air is supplied from a vertical scavenging pump driven from the crankshaft and located between the two pairs of cylinders. Fresh water cooling is used throughout, supplied from steam driven circulating pumps, the fresh water being of course itself cooled by the circulation of sea water around it in a special cooler.

Details of the Vessel

The new vessel is very similar in hull dimensions to standard steamers which Doxfords have built for several years past. The following are the details and the dimensions:

Length between prependiculars	420 feet
Maximum beam	54 feet
Maximum draft	25 feet 6 inches
Deadweight cargo capacity, tons	9,400
Speed, knots	10½ to 11
Indicated horsepower	3,000

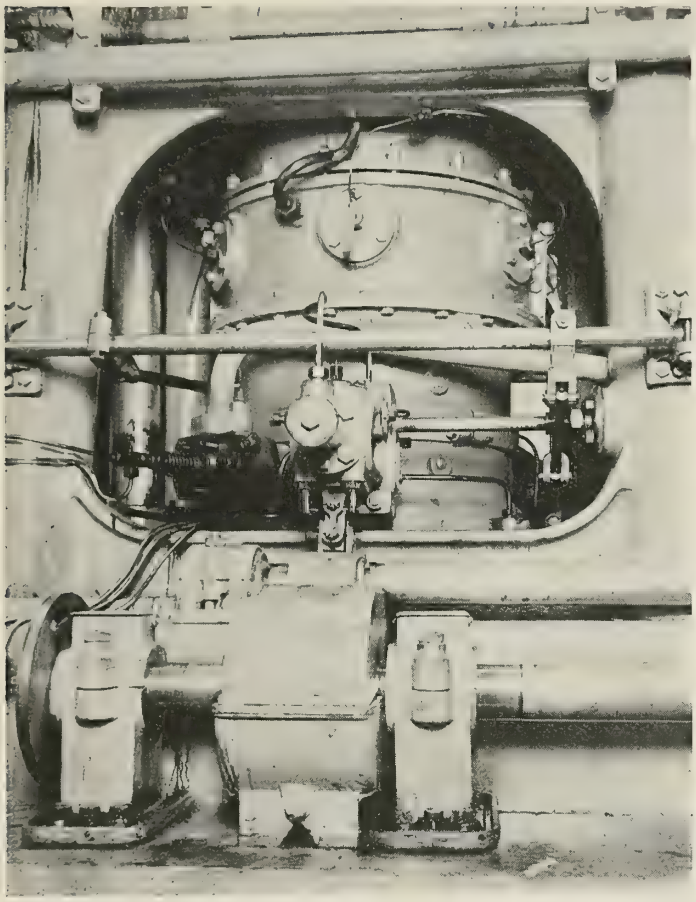
No special point of interest attaches to the construction of the hull, as it represents a cargo ship of normal design. The engine room is located slightly aft of amidships and, as for special reasons, all the auxiliary machinery is steam driven, two large boilers are installed in addition to the propelling and auxiliary plant. It is unusual in these days to find a motorship equipped with steam auxiliaries as it has been definitely proved that, in spite of the higher capital costs of an electrical plant, the saving in running expenses is so considerable that the increased expenditure is rapidly repaid.

Unusual Features of the Doxford Engine

The main engine develops its full power of 3,000 indicated horsepower at 77 revolutions per minute, which inci-

Control of the Engine

The control of the engine is simplicity itself and is effected solely by hand without the use of compressed air as is neces-



A Close View of One of the Cylinders of the Doxford Engine, Showing a Fuel Valve Through Which the Fuel Is Passed at a Pressure of 9,000 Pounds Per Square Inch

sary on all four cycle engines. A hand lever suffices to move the camshaft fore and aft to bring the astern cam (mounted side by side with the ahead cams on the camshaft) into operation. Starting and maneuvering are then effected by a small hand wheel and the control is much the same as with a steam engine, the hand wheel being gradually turned more and more to increase the speed. Its first action is to cause the levers actuating the starting valves to come on to their cams, thus allowing compressed air to be admitted to the cylinders and to start up the engine. On rotating the starting wheel further, the starting valve levers are taken out of action and those operating the fuel valves come on to their cams when the engine fires in the normal manner. Increased speed is attained by altering the lift of the fuel valves, this being carried out when the control wheel is rotated still further.

Engine Not of Cold Starting Type

One peculiarity of the Doxford engine is that as the compression is low, being no more than 280 pounds per square inch, it will not start up from cold and therefore has to be heated by passing steam through the pistons. This is a process taking about a couple of hours, so that this motor is not of the cold starting type and indeed cannot exactly be termed a Diesel engine at all.

Judging from the performance of the previous vessel with similar machinery, the *Dominion Miller* will have a daily fuel consumption of about 9½ tons for a speed of between 10 and 10½ knots when carrying her full cargo of 9,400 tons. According to Doxfords' experience, this compares with about 45 tons of coal on a corresponding steamer or about 25 tons of oil on a ship equipped with oil-fired boilers. The saving on the fuel bill is therefore on a large scale, particularly if it is found that the engine will operate successfully on boiler oil.

Application of Electricity to Deck and Engine Room Auxiliaries*

By C. H. Giroux†

As far back as 1900 the battleships *Kearsarge* and *Kentucky* were equipped extensively with electric auxiliaries and since that time this method of drive has been largely adopted by the Navy Department for all classes of ships. In spite of this fact there has been comparatively little progress made along similar lines in our merchant marine.

At the present time when cargo is scarce and competition is keen and when the supply of American vessels exceeds the demand, the shipowner must not overlook even the smallest item entering into the cost of operating vessels, otherwise the business may be a complete failure. A recent analysis of the performance of a large cargo vessel shows a return of 22 percent on the investment for electric auxiliaries. Where else can capital be invested with an equal return?

The problem of those who are advocating the general use of electricity on merchant vessels is first, to prove conclusively that electrical apparatus can be made reliable under marine conditions and then that the economy and low maintenance will warrant the investment of the necessary capital.

At the present time there are six steamships and two Diesel ships in merchant service propelled by electricity, the equipment for which was built by the General Electric Company. These ships, in charge of chief engineers having no previous experience with electrical apparatus, have made many voyages under all kinds of sea conditions and have proven themselves to be thoroughly dependable.

The General Electric Company has had a wonderful opportunity and has taken the trouble to make a thorough study of the operating conditions on many classes of merchant ships and has laid out plans whereby these same ships could save as much as ten or fifteen percent in the fuel consumption by the use of electric auxiliaries and by effecting a proper heat balance.

It is conservatively estimated that on a freight vessel propelled by a 2,500 shaft horsepower geared turbine, operating at sea for 220 days per year, the saving in fuel alone, which could be effected by the use of electrically driven auxiliaries, amounts to at least nine thousand dollars per annum.

The saving when the ship is in port is even greater than when at sea. The port consumption of cargo vessels with steam machinery varies from fifty to one hundred barrels of fuel per day when handling cargo, depending upon the size of the ship and the number of winches in use. These same ships, if equipped with electric engine room and deck auxiliaries, would consume from one-half to one-third of this fuel.

Little emphasis need be placed on the economy of electric auxiliaries when used with motorships for here the results are so remarkable that there is no basis of argument. I have extracts from the logs from two motorships, each driven by two 500 brake horsepower Diesel engines, one equipped with steam and the other with electric auxiliaries.

The donkey boiler for feeding the steam auxiliaries required an average of 557 gallons of oil per day at sea as compared with 42.5 gallons taken by the auxiliary engine for driving the electric motors.

On the motorship *Kennicott*, where electricity is used for all auxiliary purposes, the port consumption when loading or discharging cargo for ten hours is less than five barrels of fuel per day. This shows the possibilities where electricity is used for power.

*Extracts from a paper read before the Ocean Marine Engineers Beneficial Association. No. 80, New York.

†Marine Engineering Department, General Electric Company, Schenectady, N. Y.

Diesel-Engined Derrick Lighter Worthington

Vessel for Service in New York Harbor Equipped With New Type of Two-Cycle Solid Injection Worthington Diesel Engine

A NEW departure in the application of Diesel propelling and auxiliary machinery is found in the recent completion by the Vinyard Shipbuilding Company at Milford, Del., from designs prepared by Eads Johnson, naval architect, New York, of the self-propelled single screw Diesel engine-driven derrick lighter *Worthington,* built to the order of the Worthington Pump and Machinery Corporation, New York, to take the place of their steam derrick *Daniel Wheeler,* used for handling the company's products

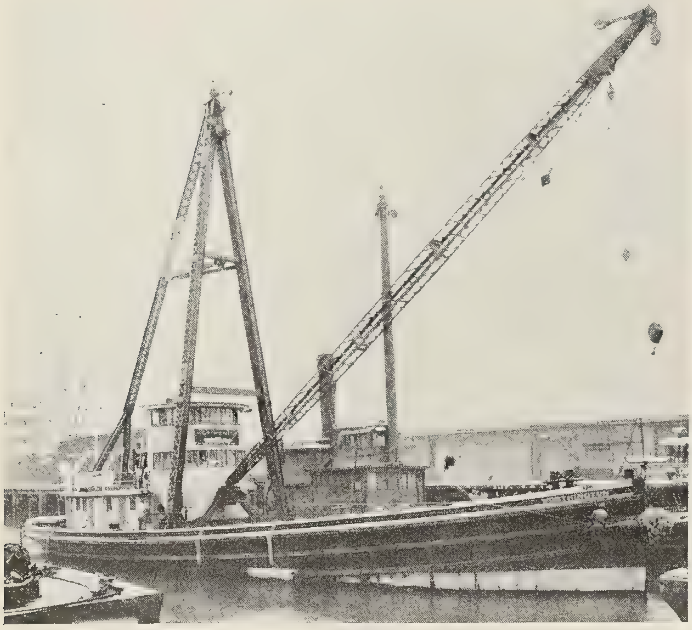


Fig. 1.—Derrick Lighter Worthington, Showing Arrangement of 20-Ton "A" Frame Derrick. Steam Lighter Daniel Wheeler in Background

in New York harbor and vicinity. Both the new and the old lighters are shown in Fig. 1.

In preparing the designs for this vessel, the naval architect collaborated with the Worthington company's engineers with a view towards achieving the most successful adaptation of this new type of power equipment to the special conditions of the service in which the boat is to be engaged. The derrick was built and installed by the Terry Manufacturing Company, New York.

The outstanding feature of this new lighter, aside from her size and the completeness of her equipment and accommodations, is the installation of a new type of Diesel engine, developed by the Worthington Pump and Machinery Corporation, for propelling the vessel and also for driving its main generator which supplies the current for the derrick motor, auxiliaries and electric lights. This engine is a two-cycle solid injection Diesel designed with a view to simplicity of construction and reliability of operation. As its weight per horsepower is about half that of the ordinary Diesel and its economy comparable with that of the ordinary Diesel, its simplicity and reliability of operation will appeal to marine engineers.

The hull of the *Worthington* is of wood, 133 feet long with a beam of 35 feet and a load draft of 10 feet. The gross tonnage is 333, the net tonnage 225. The hull is of unusually heavy construction to withstand the hard usage incident to service around the docks and harbor shipping and is full bodied in order to provide the necessary stability for operating the cargo derrick at long radii.

Derrick Equipment

An "A" frame derrick of 20 tons lifting capacity, of steel lattice work construction, is mounted abaft the midship line with a back leg extending to within a few feet of the stern. About 15 feet above the deck this back leg is divided into a fish tail, the two parts spreading out to within five feet of the rail on each side. The top of the "A" frame stands 70 feet above the main deck line. The derrick boom is 90 feet long and is stepped on a tripod base seven feet above the main deck. This construction permits the lighter to lie alongside high sided ships and handle cargo on deck or in the holds without using the ship's own cargo booms.

The derrick is mounted on foundations built up on fore and aft and athwartship trusses under the main deck and in the vicinity of the trusses and spaces between the frames and between the deck beams are filled in solid with timbers. Large U-bolts hold the derrick legs down and pass through the trusses to the hull framing so that all the stresses from the derrick are carried right to the bottom of the hull.

In a compartment just forward of the engine room is located the hoisting engine for operating the derrick. This is a five drum machine driven by a 25 horsepower General Electric motor and built by the National Hoisting Engine Company. The wire cable from each drum is led by means of suitable pulleys to a point directly beneath the derrick, then up through the deck to its proper place on the derrick. By means of reach rods and bell cranks the controls for all drums are operated by a bank of levers located in a glass enclosed operating room directly beneath the pilot house. A controller of the trolley car type for controlling the hoisting engine motor is also located in this room.

General Arrangement

In the space between the derrick "A" frame and the back leg is located the deck house containing living quarters for the crew, the operating room for controlling the derrick and the pilot house. From the "A" frame to the stem of the boat is clear deck space for cargo stowage. On boats of this type it is customary to carry all cargo on deck but on this vessel a large main deck hatch is provided so that perishable freight can be stowed in the hold, if it should be necessary to keep it on board for any great length of time.

At the level of the main deck in the deck house are two single and two double staterooms, one for the chief engineer, one for the assistant engineer, one for a deckhand and the cook and one for two deck hands. At the after end of the deck house on the port side is the galley, opening into the messroom on the starboard side. On the second deck in the deck house are two staterooms, one for the captain and one for the mate. On the same level and just forward of these two staterooms is the derrick operating room. Above the operating room is the pilot house, handsomely finished in hardwood. The appointments and finish of all the living quarters are somewhat above the average practice in harbor work boats.

The engine room is located in the stern and contains the main propelling engine, the electric plant for supplying cur-

rent to the derrick motor, auxiliaries and electric lights, an emergency lighting set, auxiliary air compressor, auxiliary lubricating oil circulating pump, auxiliary cooling water circulating pump, oil cooler, hot water heating boiler and starting air tanks.

Propelling Machinery

The main engine is a Worthington two cycle, solid injection, four cylinder Diesel engine, with cylinders 15¼ inches diameter by 16 inches stroke, developing 300 brake horsepower at 275 revolutions per minute. All of the control gear and fuel pumps are included in a sub-assembly at the forward end of the engine. On the after end, just abaft the flywheel is another sub-assembly consisting of a lubricating oil circulating pump, cooling water circulating pump, starting air compressor and mechanical cylinder lubricators, all driven from one eccentric. Attached to the aft end of the engine bed is a S. K. F. ball thrust bearing.

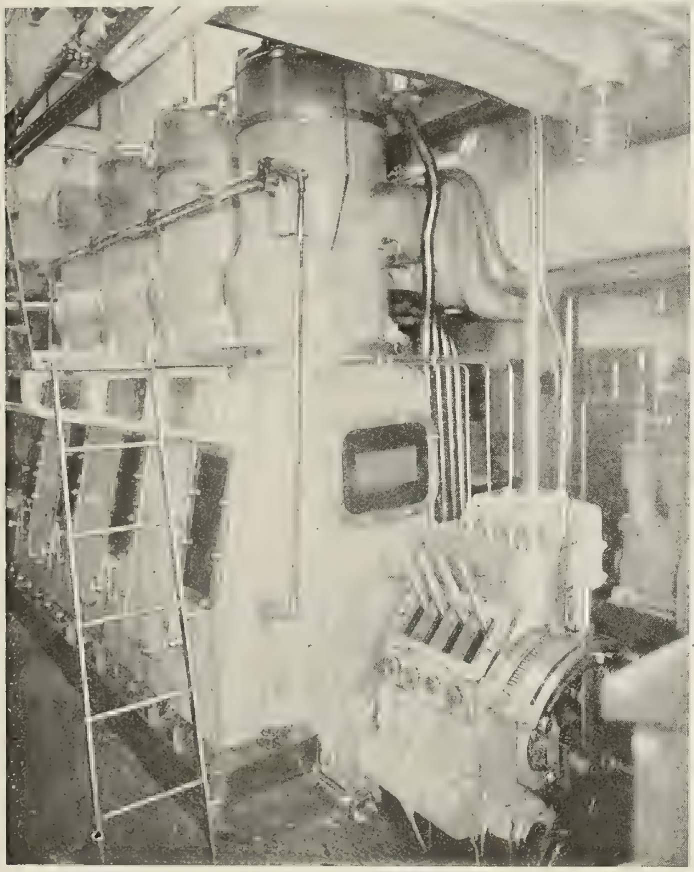

Fig. 2.—Starboard Side, Looking Aft, of 300 Horsepower Worthington Diesel Propelling Engine, Showing Control Assembly. All Operations Are Controlled from This Point

On the starboard side, forward is the electric generating plant consisting of a Worthington two cycle, solid injection, two cylinder, Diesel engine of 50 horsepower direct connected to a General Electric 38 kilowatt, direct current generator delivering current at 220 volts. A cooling water circulating pump, a bilge pump and a lubricating oil circulating pump are attached to this engine. This set supplies current for operating the derrick engine, the auxiliary air compressor, auxiliary pump and electric lights.

Auxiliaries

For pumping up starting air when the main engine compressor is not in operation, a Blake & Knowles (manufactured by the Worthington Company), two stage, motor driven compressor is provided. This compressor is provided with a Cutler Hammer automatic starter which can be set to maintain the air in the starting air reservoirs at any desired pressure, a combined pressure gage and electric switch making contact and closing the starting circuit to the air compressor motor when the air pressure in the tanks falls to the desired minimum and breaking contact when full pressure is reached. As long as the main attached compressor keeps the pressure in the starting air tanks between 250 and 350 pounds the auxiliary compressor does not operate but if engine maneuvers are made so frequently that the attached compressor cannot keep up the supply and the pressure falls to 250 pounds the starter gage closes the circuit, the auxiliary compressor starts without attention from the engineer and keeps running until the air pressure reaches 350 pounds, when the starter gage opens the circuit and the auxiliary compressor stops.

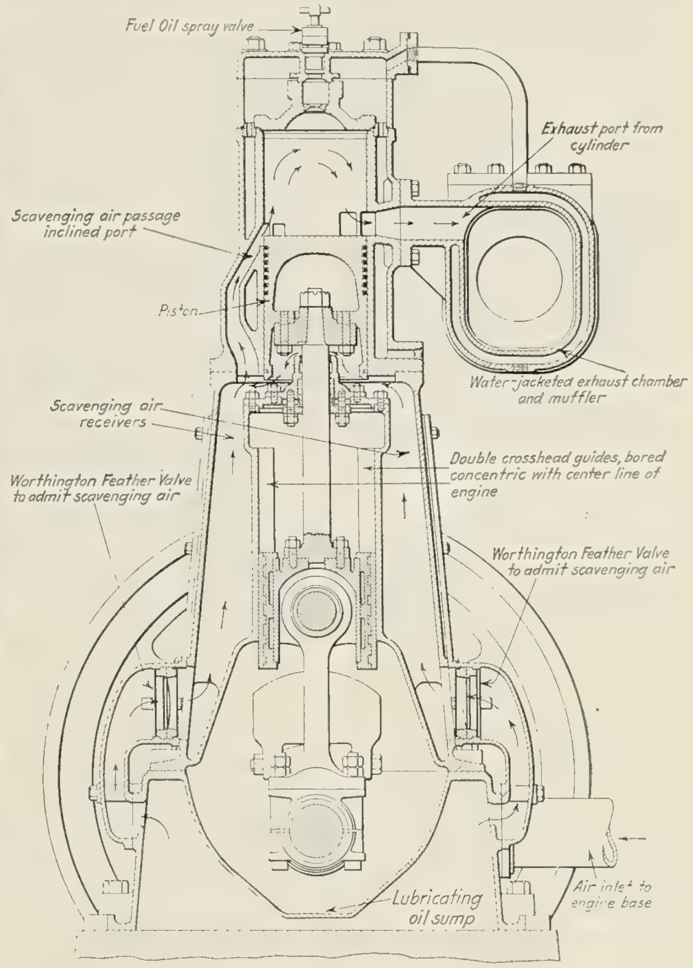

Fig. 3.—Section Through Engine

For emergency use, if the lubricating oil pump on either the main or auxiliary engine stops working, a motor driven rotary oil pump is provided. For emergency cooling water circulation a Worthington 2-inch volute, centrifugal, motor driven pump is provided. This pump has a connection to the bilge and can also be used to supply water to the fire hydrants on deck.

A Griscom-Russell vertical oil cooler is located in a very accessible position on the port side of the main engine and is so connected that it may be used to cool the bearing lubricating oil or in cold weather, if the oil is too stiff for proper circulation, the hot jacket water from the engine may be circulated through the cooler and the oil heated.

Electric Plant

For supplying current for lighting the boat or operating any of the auxiliary pumps when the 50 horsepower auxiliary set is shut down a Cummins oil engine of 7 horsepower is

provided, connected to a 6 kilowatt Triumph, direct current generator. This engine operates on the Hvid principle, burns the same fuel as the main engine and can be started by hand. If for any reason all the starting air should be lost, so that the 50 horsepower auxiliary engine cannot be started, this small set can be started by hand and will supply power enough to operate the auxiliary air compressor and pump up the starting air.

Starting air at 350 pounds pressure is stored in six cylindrical tanks of about 20 cubic feet capacity each, located in the extreme aft end of the engine room. This greatly ex-

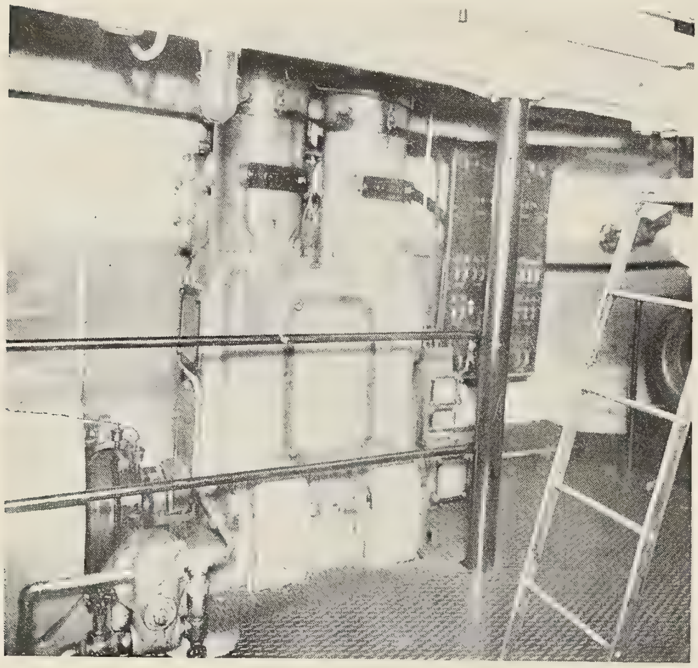

Fig. 4.—Worthington 50 Horsepower Diesel Engine Connected to 38 Kilowatt Generator for Supplying Current for Operating Derrick and All Auxiliaries. Switchboard in Background

ceeds the air requirements for the engine but the owners of the boat wished to be on the safe side and insure the boat against loss of maneuvering power in situations where very complicated maneuvers are required around crowded docks or among harbor shipping. In service it has been found that for normal operation two of these tanks are ample to meet the requirements.

New Type of Air Whistle Installed

Air at 100 pounds pressure for operating the whistle is stored in a tank that is a duplicate of the starting air tanks. Air is supplied to it through a reducing valve from the starting air reservoir. This tank was made of the same strength as the starting air tanks as a safety precaution in case the reducing valve should get out of order and permit full pressure of air to enter the tank.

In place of the conventional type of air whistle, which is notoriously ineffective as a sound producer and very extravagant in its use of air, the *Worthington* carries on top of the pilot house a Strombos duplex sound signal. This is a most effective sound device producing a very pleasing organ note, audible over long distances and requiring so little air that it is operated from a ¼-inch pipe.

The fuel supply is carried in two cylindrical steel tanks, of 4 tons capacity each, located outboard, one on each side in the hoisting engine compartment just forward of the engine room. At the main deck level in the engine room entrance, just above the main engine are located two daily service tanks each of sufficient capacity to operate the main engine continuously for six hours. A small pump driven from the crankshaft of the 50 horsepower engine transfers oil from the main tanks to the service tanks and a hand operated oil pump is provided as a standby. On the port side just forward of the fuel tank is a fresh water storage tank, while in a corresponding position on the starboard side is the lubricating oil storage tank.

Fire Fighting Equipment

In addition to the usual fire fighting equipment required by law additional protection against oil fires is provided in the form of a Foamite Firefoam engine of 80 gallons capacity installed in the forward part of the engine room hatch with sufficient hose attached to reach any part of the boat. In case of fire this machine is put into operation simply by opening one valve and the 80 gallons of mixture will produce 700 gallons of fire smothering foam under sufficient pressure to project it 50 feet from the hose nozzle. So effective is this apparatus for fighting oil fires that a very material reduction in insurance rate is granted by the underwriters where it is installed.

For heating the boat an Arcola hot water system of the ordinary house heating type is installed, the heating unit being located in the engine room. During the severe weather of the past winter this system proved so effective that it was found necessary to remove some of the radiators from the living quarters to reduce the heating effect.

Deck Machinery

For use in warping the vessel, pulling on lines, etc., a warping winch, driven by a 10 horsepower motor is located inside the deck house in the forward end of the engine room hatch, with a through shaft extending outside the deck house on each side and a drum on each end of the shaft.

It is worthy of comment that the boat was brought from

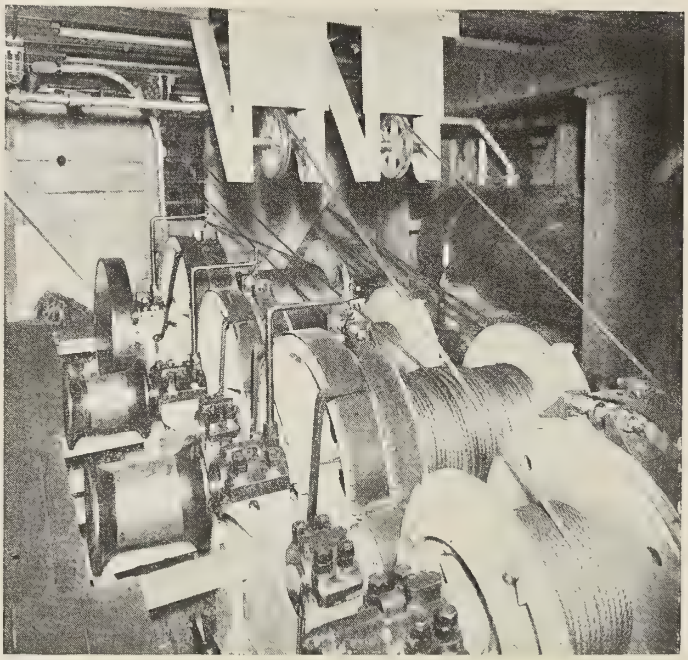

Fig. 5.—Electric Motor Operated Hoisting Engine for Controlling All Derrick Operations

the builders' yard to deep water in Delaware Bay through the shallow and tortuous water of Missapillion Creek under its own power, a trip requiring six days of almost constant maneuvering with the main engine. During this time the engine, although new and not "run in," met all the requirements of rapidly repeated maneuvers in a completely satisfactory manner, after which the vessel completed a sea trip in severe winter weather to New York without the slightest interruption.

Combined Ore and Oil Carrier Bethore, of 20,500 Tons Deadweight, Just Completed at Sparrow's Point (Md.) Plant of Bethlehem Shipbuilding Corporation, Ltd.

STEAMSHIP BETHORE COMPLETED

20,500-Ton Combination Ore and Oil Vessel Built by Bethlehem Shipbuilding Corp., Ltd.

THE S. S. *Bethore* delivered to the Ore Steamship Corporation on February 11, 1922, at the Sparrow's Point, Md., plant of the Bethlehem Shipbuilding Corporation, Ltd., is the second of the large combination ore and oil vessels to be completed at that plant. The first was the *G. Harrison Smith,* delivered to the International Petroleum Company on September 12, 1921.

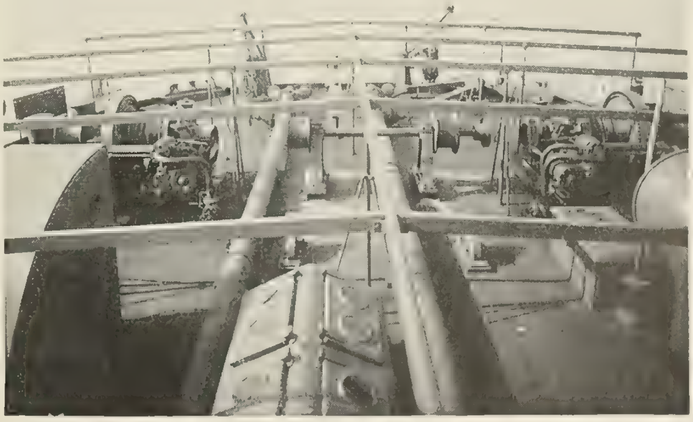
The commissioning of these steamers inaugurates the entry into service of a new type of vessel that has been developed to meet an economic demand in the construction of oil carriers. The *Bethore* is arranged with separate cargo spaces so designed and located that either a full load of oil or a full load of ore can be carried, or general cargo equal to approximately from one-half to one-third the deadweight capacity, according to density, can be carried. The utility of this type of vessel is apparent when it is recognized that it provides means for making a profitable return voyage after a cargo of oil has been delivered, thus enabling the ship owner to obtain 100 percent service from his fleet.

The ordinary tanker, as developed to date, is especially efficient in handling and transporting oil cargoes, yet suffers from the necessity of return voyages made in ballast. This condition means an economic loss which has been accepted as a necessary part of the industry. The advent of the combination ore and oil vessel, however, changes this situation and makes possible a greater return on the investment. Shipowners and operators are thoroughly aware of the necessity for economical operation and the importance of keeping their fleet moving with cargoes during the greatest possible number of days in the year, especially with present operating costs. That the construction of combination vessels is not necessarily confined to oil carriers, but may be applied as well to other types of freighters, is evidenced by the construction of two combination coal and ore carriers now building at the Union Plant, San Francisco, of the Bethlehem Corporation.

The *Bethore* is the first combination ore and oil vessel under American registry and ranks as one of the largest of all freight vessels afloat. There are undeniable economies and advantages in the use of vessels of great carrying capacity when conditions in their trade routes allow their use. This is true in the case of the *Bethore,* where the dimensions have been limited only by the depth of water available at loading and discharging terminals.

In design, the *Bethore* is of the patent combination ore and oil type and is similar, with some exceptions, to the *Marore* and *Steelore* now under construction at the Sparrow's Point plant and described in the April, 1921, issue of this paper. She was designed specially for carrying a cargo of oil from Mexico to South America, where the oil is to be discharged and a cargo of ore taken on for the United States,

Looking Aft from Bridge Deck, Showing 12-Inch Oil Cargo Discharge Line and Ore Hold Hatch Covers



Looking Aft on Poop Deck, Showing Two 12-Inch Stern Oil Cargo Discharge Lines

thus eliminating the necessity of making the return voyage under ballast as usually made by the ordinary tanker. General cargo can be carried on the trip to Mexico.

The general dimensions of the *Bethore* are in brief as follows: Length overall, 572 feet; length between perpendiculars, 550 feet; breadth, molded, 72 feet; molded depth, 44 feet; deadweight capacity, 20,500 tons, and displacement, 29,967 tons. Loaded, the draft is 32 feet 4⅛ inches, and light, the draft is 11 feet 3½ inches. The framing is longitudinal and the vessel is classed to the highest rating of the American Bureau of Shipping and British Corporation.

The principal cargo spaces in the *Bethore* consist of the cargo oil tanks and fuel oil tanks and the ore holds. The latter occupy a space 30 feet wide by 30 feet deep for a distance of 360 feet through the hull of the vessel, and are elevated 14 feet above the keel, which feature constitutes one of the inherent advantages of this type of ore carrying vessel. This ore space is divided by watertight bulkheads into three compartments. The oil cargo space contains 741,294 cubic feet, the fuel oil space, 141,160 cubic feet, and the ore cargo space of the three holds, 367,120 cubic feet.

The forward ore cargo hold is served by two hatches 30 feet long and one 19 feet long. The middle hold is served by three 30-foot hatches, while the after hold is served by two 30-foot and one 25-foot hatch. All hatches are 30 feet wide, the full width of the ore hold, and are of the corrugated patent Hogg-Carr type. Ten kingposts, with eighteen 36-foot Oregon pine booms of three tons capacity are provided for the handling of ore or general cargo in case the ship engages in a trade not having terminal facilities for loading and unloading. The ten 8¼ by 10-inch winches which handle the tackle for raising the hatch covers are available for working the ¾-inch diameter wire rope whips on the cargo booms.

The loading and unloading of an oil cargo is similar to the operations of an ordinary tanker.

In unloading ore, two 15-ton grab bucket unloaders will unload the vessel in about 40 hours.

The main engines in the *Bethore* are Bethlehem triple expansion reciprocating engines with 25-inch, 41-inch and 68-inch diameter cylinders and a 48-inch stroke. Steam is supplied by three Scotch boilers, 17 feet 6 inches in diameter by 12 feet long, built at the Sparrow's Point plant, fitted with Howden's system of forced draft and with the Bethlehem-Dahl mechanical oil burning system. In general both the engine room and deck auxiliaries, including the pumps, steering gear and mooring winches, were built by the Bethlehem Shipbuilding Corporation.

On her trial trips, on February 7 and 8, the *Bethore* more than met her requirements for speed. This vessel was designed for a speed of 11½ knots and over a measured mile off Kent Island developed a speed of 12.125 knots. A mean indicated horsepower of 5,557 was developed at 86.5 revolutions per minute.

National Merchant Marine Association Convenes

(*Continued from page* 228)

were not willing to remain at the mercy of foreign steamship lines but that our steamship operators must consent to be regulated and see their obligations to the shipper clearly defined.

Admiral Benson Given Ovation

Three lusty cheers and loud applause were given to Admiral Benson, a patriot and a fighter, who, after making an enviable reputation in the Navy, and, notwithstanding the fact that he was entitled to retirement from active service, was not afraid to handle the Shipping Board and its great problems practically alone in the face of acrimonious criticism.

The Admiral responded with a few words of explanation of the difficulties that he had labored under without the support of a full board before Mr. Harding's election and he also spoke of the necessity that he felt against doing anything to embarrass the incoming administration.

Mr. Franklin, president of the International Mercantile Marine Company, made a few extemporaneous remarks. He said that the President's message was excellent and exceedingly interesting even to people not in shipping. He hoped that all marine organizations would get behind the Shipping Bill as there was nothing so important for our merchant marine as this legislation.

Mr. Franklin said that it had a far better chance of passing than any previous bill and that, for the first time, support for such a measure could be obtained from the country at large.

Importance of Tramp Ships

Mr. Charles H. Potter, president of the United States Ship Operators' Association, stated that the Shipping Board selected its operating agents from owning and non-owning companies but that he hoped that before another year rolled around all these operators would then be classed as owners. Referring to the operation of tramp vessels by other countries he said in part:

"It is the policy of the Shipping Board to encourage and aid in the development of fast passenger, mail and cargo liners, also berth operations—and rightly so—for the very good reason that the Jones Bill so requires; but why, I ask, should the Shipping Board entirely and absolutely ignore tramp operations? I anticipate the reply will be to the effect that tramp operations are unprofitable—so are the operations of the combination passenger and cargo lines; also regular berth operations with possibly one or two exceptions. I submit that tramp operation is vital and therefore necessary to the ultimate success of a merchant marine. It is reported that since January 1, 1922, 242 foreign tramp steamers and only 51 American steamers have been chartered to transport bulk cargoes, principally from Atlantic United States ports and West Indian ports. These figures should be convincing evidence that foreign competitors are on the job; that they are taking advantage of our inactivities and short-sighted policy; and unless Government aid (either through an appropriation or subsidy) is forthcoming, and, I might add, revision of our antiquated and hampering navigation laws effected, we cannot hope to attain the goal to which we as a nation should aspire.

"The success of the British merchant marine is undoubtedly due to the large number of tramp owners rather than to the larger companies or combinations. Before the war the British fleet was divided about 60 percent tramp—40 percent liners. In recent years the larger companies or lines have deemed it necessary to buy tramp fleets in order that they might utilize these tramp vessels in supplementing the line ships on a berth controlled by conference. The tramps are not under conference regulations, and evasion of the conference rules was obtained by using uncontrolled tramps in a supplementary service. The Scandinavian countries, who have been most successful in shipping, have been principally tramp owners. Japan has also encouraged and developed its tramp tonnage. France and Italy have been principally owners of line vessels and their success has been very limited."

At the conclusion of the convention the delegates were received at the White House by the President. The President expressed his gratification at the assistance which the members of the Association had been able to render in studying the problems of marine legislation as applied to shipping.

Twisting Moments of Reciprocating Engines

Determination by Graphical Method and Use of Mathematical Formulae—Application of the Formulae

By Joseph Hecking*

THE laying-out of the twisting moment diagrams for reciprocating engines requires time and care. The work is considerably facilitated by the use of the graphical method, wherein the twisting moment at any crank angle equals the piston load at this angle multiplied by the distance between the center of the shaft and the intersection of the connecting rod with the horizontal centerline of the shaft, noted as "a" in the figures.

The mathematical formula for the graphical method is the following:

In accordance with the triangle of forces (Fig. 1).

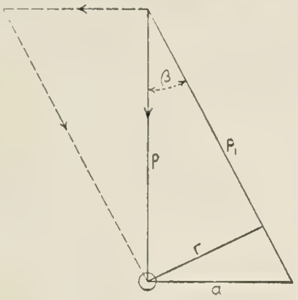


Fig. 1

$$P_1 = \frac{P}{\cos\beta}$$

where P = piston load, P_1 = force in the direction of the connecting rod. According to the law of similar triangles we have:

$$\frac{P_1}{a} = \frac{P}{r}$$

$$a \times P = P_1 \times r$$

The piston pressure to be taken from the indicator card at a point corresponding to the relative position of piston to crank. The inertia pressure per square inch of piston area at the various positions of the piston must be considered in the value of "p" and may be calculated for each engine or an average value may be assumed, depending on the type of the engine. It should be remembered that inertia is to be deducted from the working pressure for the first half of the stroke and to be added for the second half.

Torque Arm

Unless the torque diagrams are laid down accurately and to a large scale, errors are apt to occur in measuring values. The results of the graphical method may be readily determined mathematically without the construction of a diagram. The dimension "a" representing the leverage of the turning force may be determined as follows (see Fig. 2):

$$R = \text{ratio of connecting rod length to crank length}$$
$$m = \sin\alpha \times r$$
$$n = \cos\alpha \times r$$
$$\sin\beta = \frac{m}{Rr} = \frac{\sin\alpha \times r}{Rr} = \frac{\sin\alpha}{R}$$
$$s = \tan\beta \times n = \tan\beta \times \cos\alpha \times r$$

For upper half of stroke:

$$a = m + s = (\sin\alpha \times r) + (\tan\beta \times \cos\alpha \times r)$$

For lower half of stroke:

$$a = m - s = (\sin\alpha \times r) - (\tan\beta \times \cos\alpha \times r)$$

Piston Position

When the crank pin has traveled to the position of angle α the piston has moved through the distance "b," and the pressure of the lower position is measured from the indicator card. The length of the indicator card is taken as 2 r. The distance "b" is determined as follows:

$$t = \cos\beta \times R\,r$$

Upper half of stroke:

$$b = (R + 1)\,r - t - n$$
$$b = (R + 1)\,r - (\cos\beta \times R\,r) - (\cos\alpha \times r)$$

Lower half of stroke:

$$b = (R + 1)\,r - t + n$$
$$b = (R + 1)\,r - (\cos\beta \times R\,r) + (\cos\alpha \times r).$$

The values of "a" and "b" have been calculated by the above formulae for each 10 degrees of the crank and are tabulated in Table I on the next page.

Example: The indicator cards shown in the figures are taken with a 375 pound spring from a 4 cycle Diesel engine 24-inch diameter, 36-inch stroke, i. e., 1 inch height of the pressure curve represents 375 pounds pressure. The length of the connecting rod is 4½ times the length of the crank, R = 4.5.

For the 40-degree position of the crank the relative position of the piston, according to the table, b = .2803 × 18 inches = 5.05 inches from the upper position. Length of card 2r = 36 inches.

The piston pressure at this point is $\frac{19}{32} \times 375 = 223$ pounds and the piston load $223 \times .7854 \times 24^2 = 100{,}800$ pounds.

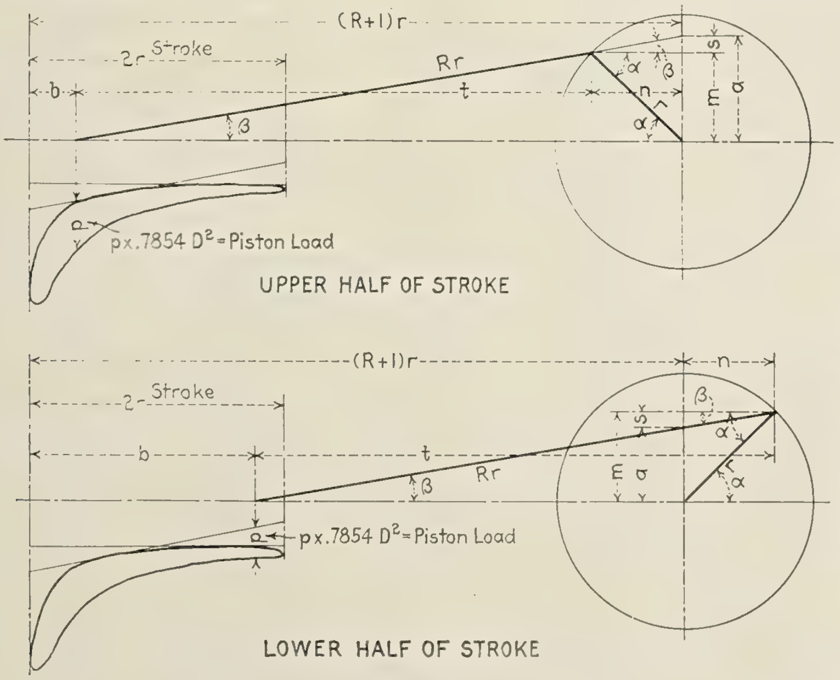

Fig. 2

*Engineer Surveyor, Scientific Department, American Bureau of Shipping, New York.

Table I—Values of "a" and "b" for Each 10 Degrees of the Crank

Crank angle from upper position	Ratio of connecting rod to crank lengths: 4		4.5		5		5.5

80	1.029	.9488	1.024	.9358	1.02	.9244	1.016	.9155
90	1	1.127	1	1.113	1	1.101	1	1.092
100	.9406	1.296	.9458	1.283	.95	1.272	.9532	1.263
110	.857	1.454	.8667	1.442	.8743	1.431	.8804	1.423
120	.7553	1.595	.7679	1.584	.7781	1.576	.7863	1.568
130	.6428	1.717	.657	1.708	.6678	1.702	.677	1.696
140	.5183	1.818	.5323	1.812	.5433	1.808	.5606	1.803
150	.391	1.897	.4035	1.894	.4134	1.891	.421	1.889
160	.2617	1.955	.2703	1.953	.2777	1.952	.2834	1.95
170	.1308	1.988	.1355	1.988	.1394	1.988	.1424	1.988
180	0	2	0	2	0	2	0	2

Values of "a" and "b" to be multiplied by "r."

Turning arm "a" $= .7533 \times r = 13.56$ inches.
Twisting moment $= 100{,}800 \times 13.56 = 1{,}365{,}000$-inch-pounds.

For angles different from those given in the table the *formulae* should be used to obtain the corresponding values of "a" and "b." For different ratios of connecting rod to crank lengths it will be sufficiently correct to interpolate between values given in the table.

Application of Formulae

In multi-cylinder *Diesel engines* the crank shaft at the after crank transmits the combined torque of all the cylinders and is, in addition, subject to bending strains. (See "Diesel Engine Crank Shafts" in Marine Engineering and Shipping Age, February, 1921.) The line shafts are subject to twisting strains only, disregarding bending strains due to their own weight, and the moment of resistance (Section modulus $\times$ working stress) should not be less than T maximum found by the above formula, i. e., $0.196\ d^3 f =$ T maximum. The position of the crank angle for T maximum will be found near the 30-degree position for all engines excepting the 4-cylinder 4-cycle, where it is located near the 110-degree position. T maximum is therefore the sum of the twisting moments of one crank at the 30-degree position plus the twisting moments of all other cranks at their position in relation to the 30-degree angle. Similarly for the 4-cylinder 4-cycle engine as mentioned above. Diesel engines are usually fitted with flywheels which have the effect of equalizing the turning effort, thus reducing T maximum and increasing T minimum for the shafting aft the flywheel. It is not advisable to take full advantage of the reduction in T maximum but rather to calculate line shafts with a somewhat higher fibre stress "f" of 7,500 to 8,000 pounds per square inch.

In *turbines and motors* the turning effort is uniform and T mean = T maximum; the working stress "f" is usually taken at 5,000 pounds per square inch.

$$T\ m = \frac{S.\ H.\ P. \times 63{,}000}{R.\ P.\ M.} = 0.196\ d^3 \times 5{,}000$$

$$d^3 = \frac{S.\ H.\ P. \times 63{,}000}{R.\ P.\ M. \times 0.196 \times 5{,}000} = \frac{S.\ H.\ P. \times 65}{R.\ P.\ M.}$$

Steam Reciprocating Engines

Years of experience and common practice have established certain constants which may be used safely in calculating shaft diameters. T m is found by the well known formulae

$$\frac{plan}{33{,}000} = \frac{T\ m \times 6.28 \times R}{12 \times 33{,}000}$$

$$\text{or } \frac{p\ S\ D^2 R}{252{,}000} = \frac{T\ m \times R}{63{,}000}$$

$$T\ m = .25\ p\ S\ D^2 \text{ where}$$

p = mean referred pressure
S = stroke in inches
D = diameter of low pressure cylinder in inches
R = revolutions per minute

For compound engines $\dfrac{T\ max.}{T\ m} = 1.45$

and T max. $= 0.363\ p\ S\ D^2$

For triple expansion engines $\dfrac{T\ max.}{T\ m} = 1.33$

and T max. $= 0.333\ p\ S\ D^2$

For quadruple expansion engines $\dfrac{T\ max.}{T\ m} = 1.25$

and T max. $= 0.313\ p\ S\ D^2$

The fibre stress for the crank shaft is taken at 6,000 pounds per square inch and for the line shaft 7,000 pounds. For the crank shafts of compound engines, for instance,

$0.196\ d^3 \times 6{,}000 = 0.363\ p\ S\ D^2$, and for the line shafts

$$0.196\ d^3 \times 7{,}000 = 0.363\ p\ S\ D^2$$

The mean referred pressure "p" is dependent on the ratio of expansions and the card or efficiency factor; it is the theoretical mean effective pressure multiplied by the card factor.

The theoretical mean effective pressure for any number of expansions may be taken from any engineering handbook.

The ratio of expansions $= \dfrac{1}{\text{percent cut-off}} \times$ ratio of cylinder volumes. Inasmuch as the stroke of all cylinders is the same, the ratio of cylinder volumes is the same as the ratio of their diameters squared.

It is more convenient to express "p" as a fraction of the absolute boiler pressure P (working pressure + 15 pounds). The process of obtaining the values of p for various cylinder ratios and engines is given in the following table taken from the *Bulletin of the American Bureau of Shipping.* The values of shaft diameters obtained from these factors represent closely the requirements of the American classification society.

Cyl. Ratio L^2/H^2	Ratio Expansion	Theoretical m. e. p.	p = m. r. p.

Steering Machinery—Merchant and Naval Types

Calculation of Forces Acting on Rudders—Power Required for Steering Engine—Description of Steam, Hydraulic and Electric Steering Gears

By George Murray

WHEN a ship is under way most of the forces acting on the rudder may be easily calculated, if we know the following particulars: Immersed area of rudder to waterline; speed of vessel; distance of center of gravity of rudder from centerline of rudderhead, usually termed center of pressure; angle the rudder makes with the centerline of ship.

Rudder Proportions

When not given by the shipbuilder the proportions of the rudder may be estimated.

$$\text{Area} = A = \frac{L \times D}{70}$$

A = immersed area of rudder in square feet.

L = Length on waterline between perpendiculars in feet.

D = draft in feet.

$$\text{Center of pressure} = L_1 = \frac{A}{D} \times C.$$

L_1 = center of pressure in feet.

A and D as for immersed area rudder.

C = a value based on the sine of rudder angle, with the following limits:

Angle 10 degrees = .248
20 degrees = .300
30 degrees = .347
35 degrees = .37
40 degrees = .391
45 degrees = .41

As the rudder stocks of vessels of ordinary proportions have their dimensions made to either the rules of a classification society in the merchant class or the accredited formula derived from experience in naval vessels the machinery operating these rudderstocks ought to conform to standard dimensions or capacities instead of the existing system, wherein the maker of this important marine auxiliary with the consent of the shipbuilder is free to install machinery with a very small margin of power over resistance. It will be noted from the July, 1920, *issue of* MARINE ENGINEERING *that Great Britain is about to set up in several districts panels with the idea of obtaining uniformity in deck fittings and auxiliaries including steering gear.*

If the rudder is rectangular and the angle the rudder makes with the centerline of the ship is 35 degrees, then the center of pressure is approximately three-eighths of its width. When the rudder is rounded the area may be obtained by Simpson's rule.

Balanced Rudders

When the rudder is balanced each part may be dealt with separately. Usually the forward part is smaller than the after part, therefore the resistance of the former would be deducted from the latter and the difference would give the actual resistance of the rudder to turning or the turning moment of the rudder.

Turning Moment

The resistance to turning or turning moment may be ascertained by substituting the proper values for the factors in the following rule:

If turning moment = M_t

Formula I. $$M_t = \frac{A \times V^2 \times L_1 \times C}{R} \times T = \text{foot pounds.}$$

A = immersed area of rudder in square feet.

V = speed of ship in knots.

L_1 = center of pressure in feet.

T = travel of chain in feet, i. e., proportion of circumference of quadrant embracing the angle "hard over" to "hard over."

R = radius in feet, center of rudder stock to center of chain on quadrant.

C_1 = a number based on the rudder angle with values as follows:

H.O. to H.O. 70 degrees = 1.8
80 degrees = 2
84 degrees = 2.5
90 degrees = 3

Alternative Method

Formula II. $M_t = A \times \sin Q \times P_1 \times L_1.$

A = immersed area rudder in square feet.

Q = angle rudder makes with centerline of ship.

L_1 = center of pressure in feet.

P_1 = pressure on rudder in pounds per square foot, i. e., $1.12V_1^2$ (see Table I).

V_1 = speed of ship in feet per second plus 10 percent.

Alternative Method

To facilitate calculations by Formula II, Table I is useful.

It is not always possible to arrive at the turning moment by the formulæ above, owing to the information supplied by the shipbuilder consisting only of the diameter of the rudder stock and probably the length, draft and speed of vessel. The turning moment is then obtained from the strength of the rudder stock. It is the practice of many makers of steering machinery to allow a stress on the rudder stock well within the limits of ultimate breaking point as Table II shows.

Table I—Pressure in Pounds Per Square Foot

Knots	Pressure P_1 Lbs. per Sq. Ft.	Knots	Pressure P_1 Lbs. per Sq. Ft.
7	189.2	17	1,118
8	247.4	18	1,253
9	313	19	1,396
10	387.3	20	1,546
11	468.7	21	1,705
12	557.4	22	1,872
13	653	23	2,046
14	758	24	2,227
15	870	25	2,416
16	990		

For the purposes of this article it will suffice to assume there is no bending moment transmitted to the rudder stock by the quadrant, tiller or other attachment and that a simple turning effort is all that we allow for, using the strength of the rudder stock in accordance with the table for a given diameter of stock. If the turning moment is given, the diameter is found as follows.

We have the strength of stock from the following familiar formula:

TABLE II—TORSIONAL STRENGTHS OF STEEL RUDDER STOCKS

Diameter, Inches.	Breaking Strength, Inch-Tons.	Elastic Limit, Inch-Tons.	Turning Moment Applied by Gear = 2/3 Elastic Limit, Inch-Tons.
5¼	846	348	232
5½	976	385	275
6	1,272	511	342
6½	1,618	575	383
6¾	1,812	644	429
7	2,020	718	479
7¼	2,245	798	532
7½	2,485	884	589
7¾	2,742	975	650
8	3,016	1,072	715
8¼	3,307	1,176	784
8½	3,617	1,286	857
8¾	3,946	1,403	935
9	4,294	1,527	1,018
9¼	4,662	1,658	1,105
9⅜	4,850	1,725	1,152
9½	5,051	1,796	1,197

$$\frac{f}{y} = \frac{M_t}{I}$$

where $y = \frac{D}{2}$; $f =$ limiting stress; $I =$ moment of inertia of section. Now $f = \frac{M_t \times D}{I \times 2} = \frac{M_t \times D}{\frac{\pi}{32} D^4 \times 2} = \frac{M_t \times 16}{\pi D^3}$

$$D^3 = \frac{M_t}{\frac{\pi}{16} f}. \quad D = \text{diameter of stock.}$$

For *f*, the usual stress allowed is 5 tons per square inch. From the foregoing, having arrived at the turning effort necessary to overcome the resistance offered by the pressure on the rudder with the ship under way, we may proceed to determine the power of the steering gear or engine.

Merchant Type Gears

In the merchant pattern of steering engine it is customary to base the engine power on the assumption that one of the cylinders in a two cylinder engine is required to overcome the friction of the gear and all the rudder connections. With a gear similar to Fig. 1 the power is obtained as follows:

Formula III. $A \times P \times 2S \times R =$ foot pounds (engine power) where

- $A =$ area of one cylinder in square inches.
- $P =$ working steam pressure in pounds per square inch.
- $S =$ stroke in feet.
- $R =$ revolutions of engine "hard over" to "hard over."

The revolutions of the engine $R = \frac{G \times H \times N}{M}$

where

- $G =$ circumference of quadrant at pitch line of chain.
- $H =$ fraction of circumference moved from H.O. to H.O.
- $N =$ number of teeth in worm wheel.
- $M =$ circumference of barrel at center of chain.

The diameter of the chain barrel should be at least 12 times the diameter of the chain.

There is no fixed ratio of engine power to turning moment but the best makers give:

$$\text{Ratio} = \frac{\text{Engine power}}{\text{Turning moment}} = 4.$$

Screw Gear

To fix the power ratio in this type of gear the following formula is the simplest:

Formula IV.

$$\text{Turning moment, } M_t = \frac{A \times V^2 \times L_1 \times C_1}{L_2} \times T_2 = \text{foot pounds}$$

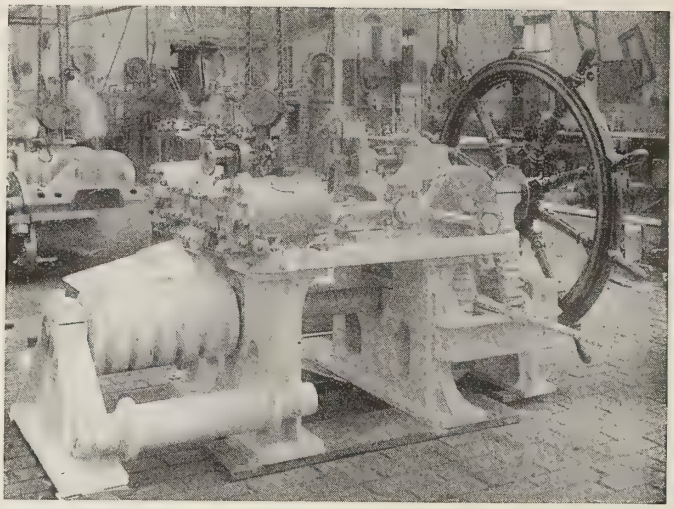

Fig. 1.—Horizontal Type of Steering Engine

where A, V, L_1 and C_1 have the values as in Formula I; T_2 is the travel in feet of the screw gear crosshead; L_2 is the shortest radius, i.e., distance from crosshead pin to center of ship when crosshead is hard over *and engine power* is obtained from Formula III.

taking $R = \frac{T_3 \times N}{p}$

where $p =$ pitch of screw in inches or lead if multiple thread and $T_3 =$ travel of crosshead pin in inches.

Having in a general manner described the methods used to fix the size of steering engines, several of the more important types of the merchant ship pattern will be briefly noted and illustrated.

Horizontal Engine with Chain Barrel

Of the many gears in use the premier position is held for small and medium sized vessels by this style of engine, no

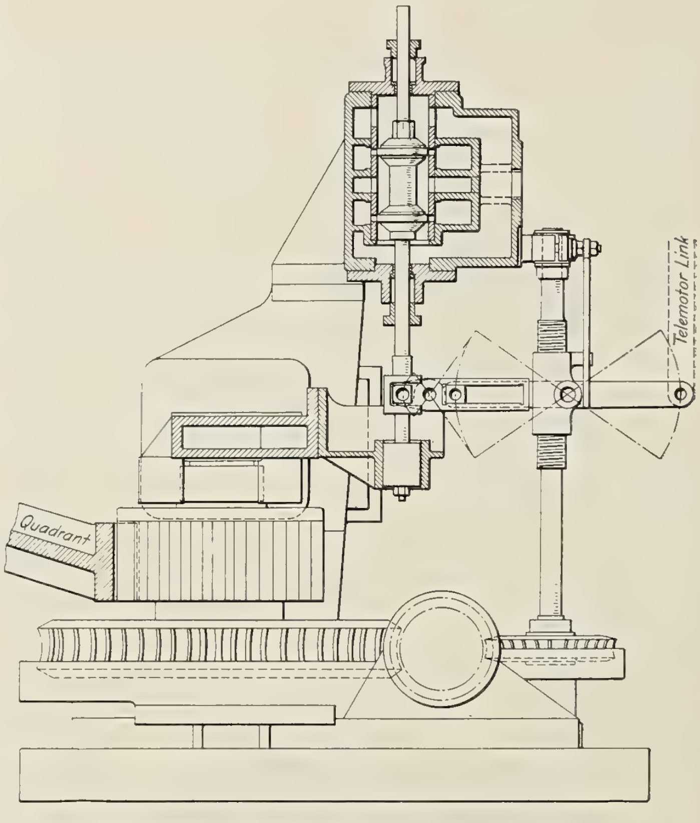

Fig. 2.—Section Through Vertical Quadrant Gear

doubt on account of its simplicity, and the scope it affords for variety of design, combined with the almost unique record it holds for safety, and the ease with which it is manipulated.

Fig. 1 illustrates a steam and hand table or horizontal gear in which the barrel is extended, the shaft being carried by a separate bracket. Guide rollers are provided and the hand gear is supported on an independent bracket firmly secured to the main cheeks by brackets, one of which serves as the fulcrum for the hand lever operating the clutch suitably disposed between the steam and hand gear wheels. As a rule the control for this gear consists of steel shafting with miter wheels and suitable supports. The vertical shaft on the gear will be noted on the illustration.

Vertical Quadrant or "Wilson Pirrie" Gear

This gear has been in favor for many years. It is very rigid and being directly connected to the rudder stock the space occupied is small and there is the advantage that long chain leads are dispensed with. In recent years many improvements for centralizing the rudder and brake gear have been a feature.

Fig. 2 shows a section through this type of gear. On the rudderhead is keyed a toothed quadrant or in the "Wilson Pirrie" type a tiller is keyed to the rudder stock and the quadrant is connected to the tiller by strong eyebolts provided with cushioning springs. The quadrant teeth mesh with a quadrant pinion mounted on a pinion shaft and, in this example, integral with the worm wheel which is rotated by means of a worm cut on the crankshaft of the steering engine.

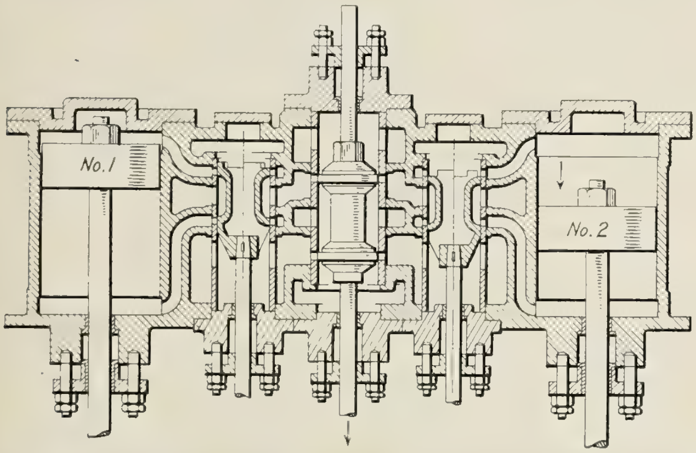

Fig. 3.—Section Through Cylinders of Vertical Steering Gear

It will be noted that telemotor gear control is fitted and a safety device known as the Stanhope lever is used to actuate the control piston, a circular guide taking any strain which might be induced by this lever arrangement. The means provided to return the control piston to its central position are clearly shown and, if taken in conjunction with the cylinder details, the action will be quite easily understood.

Control of the Gear

Fig. 3 is a longitudinal section through the cylinder of a vertical quadrant gear. The control piston is shown in mid position; No. 1 piston is at the top of stroke; No. 2 piston at mid stroke. The eccentrics are set in advance of the crank, therefore No. 1 valve is at mid stroke and No. 2 valve at the bottom of its stroke or travel. If the telemotor link is pushed down with the arrangement in Fig. 2 the control piston moves down causing piston No. 2 to move down, rotating the worm shaft and small worm wheel on the control shaft. This shaft has a screw on which a suitable thread is cut and carries the lever fulcrum nut by means of which the reversing or centralizing of the control piston is effected.

Hydraulic Steering Gear

As there was no reliable controlling mechanism till a few years ago this gear did not receive the attention it deserved, but with the advent of the motorship, owners and shipbuilders desiring to eliminate steam gears have adopted this type.

Fig. 4 shows a modern gear which is a combination, consisting of a constantly running electric motor, driving a variable speed and reversible pump, which delivers oil under pressure to either of two cylinders. These cylinders are fitted with rams having bearings for the journals of a steel crosshead, provided with an aperture to take the circular end of a forged steel tiller securely keyed to the rudder stock. The control for this gear is an adaptation of the telemotor, giving very sensitive governing and great latitude in maneuvering.

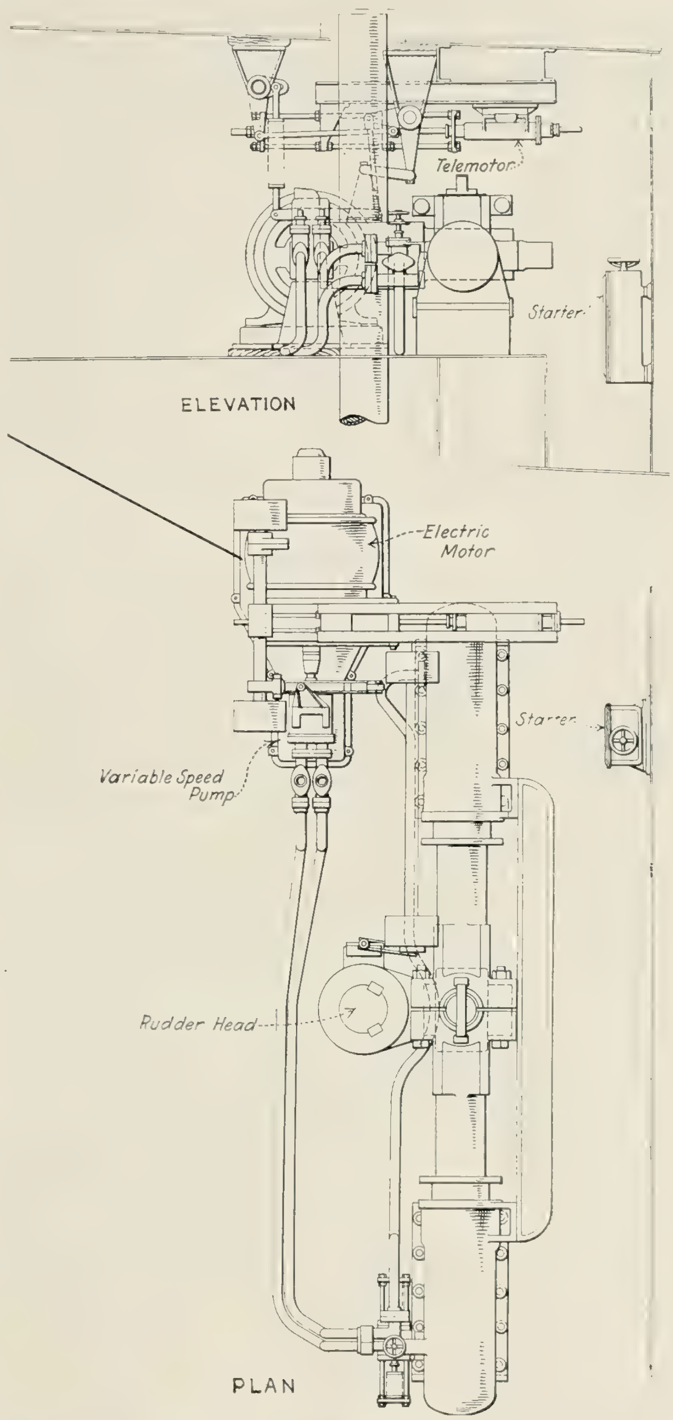

Fig. 4.—Hydraulic Steering Gear

If we suppose the levers in the relay system, which controls the variable speed pump, to be moved down on the left

by the spring link, this sets the pump in motion and transmits oil under pressure to the cylinder and forces the ram to one side. In order to maintain the position assigned to the rudder by the steerer, what is known as a differential gear is fitted. This gear returns the eccentric of the pump to its neutral position, when no oil is transmitted, thus holding the rudder at the proper angle.

Steam Screw Gears

Screw gears operated by hand were among the first styles used. This gear has much to commend it. It is self-holding, is of simple construction, will work well after considerable wear and may be constructed to suit any size and type of vessel.

Fig. 5 shows a well known type of gear for use on a large liner. The screw is placed forward of the rudder stock, strong

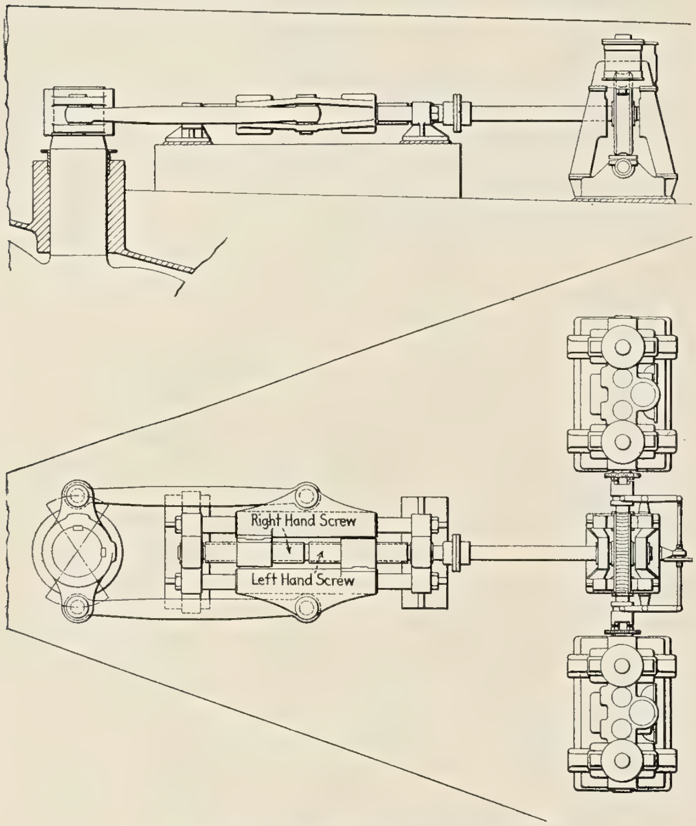

Fig. 5.—Steam Screw Steering Gear

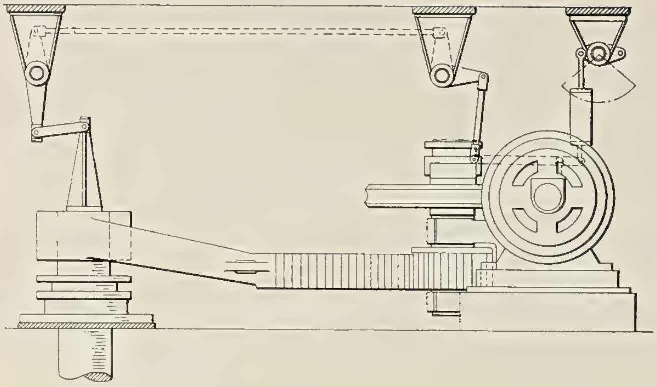
steel connecting rods being attached to a forged steel crosshead keyed to the rudder stock. On an extension of the screw shaft is fitted a worm wheel which gears with a worm driven by the steering engines. The engines are of the marine pattern. One engine acts as a standby. A clutch gear is arranged so that as one engine is disengaged the other is coupled to the worm shaft.

Naval Gear

In British naval practice the most common style is the right and left hand screw gear placed in a compartment near the rudder, with a train of cast steel spur wheels as the reduction gear between the line shaft from the steering engine (which is usually placed in the engine room) and the screw shaft. Occasionally there are two screw shafts, side by side, one having a right and the other a left hand thread. The nut on either screw shaft is provided with an opening to take one end of the connecting rod, the other end of which fits a similar opening in the forged steel crosshead keyed on the rudder stock.

There is usually an auxiliary means of steering consisting of several large handwheels mounted on a shaft which is clutched to the screw gear simultaneously with the withdrawing of the engine clutch. An alternative gear consisting of a William Janney or Hele-Shaw variable speed hydraulic



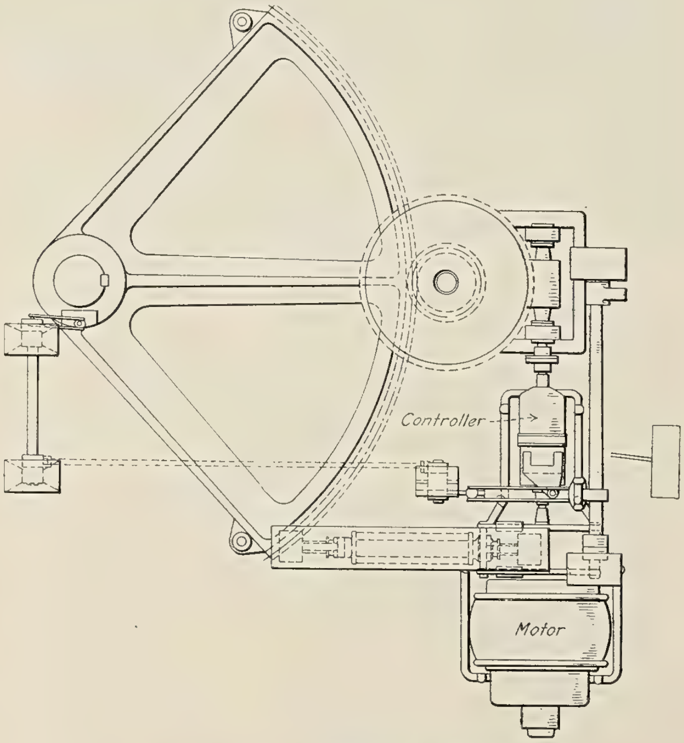


Fig. 6.—Electric Quadrant Steering Gear

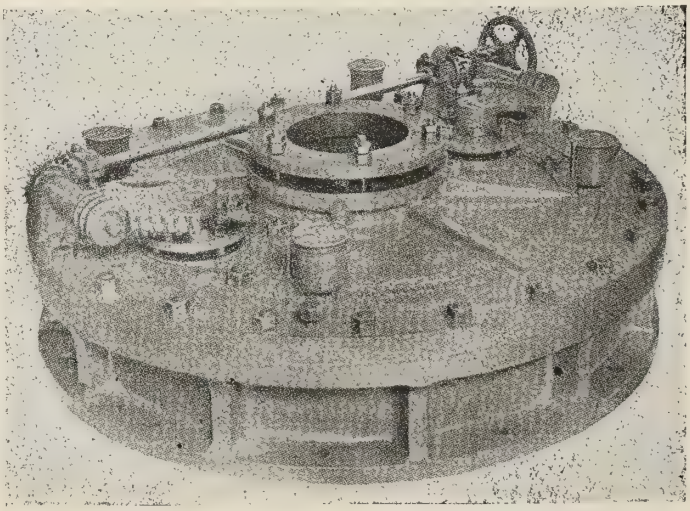

Fig. 7.—Outside View of Rudder Brake

motor with an electric motor as its prime mover is a potent feature of the newest vessels.

Table III. Particulars of Recent Steam Screw Gears

Turning Moment, Foot-Tons	Rudder Stock Diameter, Inches	Diameter of Screw, Inches	Engine Dimensions, Inches	Weight of Engine, Pounds	Weight of Screw Gear, Pounds
20	7	4½	5–5 / 5	1,120	3,136
60	9	5½	7–7 / 6	2,016	3,584
100	11	6½	8–8 / 9	3,920	4,480
200	15½	7½	10–10 / 12	6,384	8,960

375	20	10¾	13–13–13 / 13	16,800	22,400
500	26	2–10¾	14–14 / 14	16,240	23,520 (each)
600	28	13	17–17–17 / 14	22,400	40,320

Electric Quadrant Gear

In the American Navy a modern adaptation of the quadrant gear has come into favor, as illustrated by Fig. 6. It consists of a toothed quadrant forced on the rudder stock, the

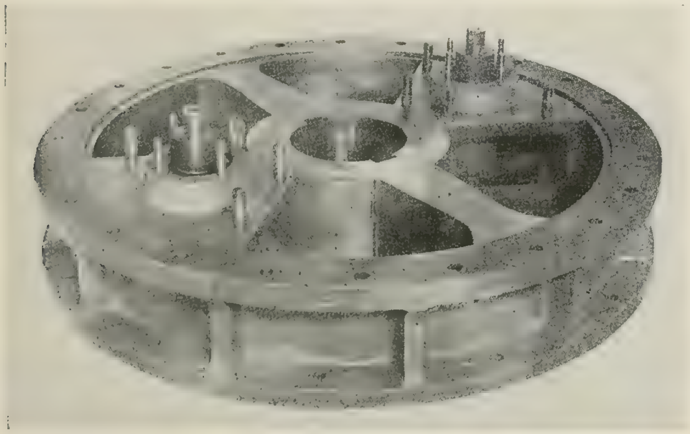

Fig. 8.—View of Rudder Brake With Cover Removed

quadrant meshing with a pinion attached to a pinion shaft. On the opposite end of this shaft a worm wheel is freely mounted but capable of becoming integral for rotating the shaft by a strong clutch. The worm wheel receives its motion by gearing with a worm operated by a variable speed motor or reversible electric motor, the starter for which is controlled by a relay system in much the same manner as the mechanism described in the paragraph dealing with "hydraulic gears."

Rudder Brakes

In self-holding steering gears such as screw gears, also in gears of the hydraulic ram type, it is not essential to introduce a brake but with other designs the importance of a good brake cannot be underestimated. A primitive form consists of a grooved metal segment attached to a tiller and a hard wood block which is forced against the segment by a long lever operated by a screw and nut.

There is also a form of brake similar to that used as buffers on the railway termini, having two hydraulic cylinders fitted with pistons, the outer ends of the piston rods being attached by pins to a crosshead on the rudder stock.

A very good example of the rotary pattern is shown in Figs. 7 and 8. The apparatus consists of a rotary piston keyed to the rudder stock and well fitted to a casing surrounding the stock, the casing having a strong flange bolted to the deck. There are four compartments filled with liquid. Ported segments with cocks and passages give access from one compartment to the other compartment situated on the same side of the rotary piston. In operation with the cocks open the rotary piston simply forces the liquid from one compartment into its neighbor, but when it is desired to cushion the rudder the cocks are partly or fully closed at will without interfering with any other part of the steering machinery.

The piston floats in oil which prevents excess of wear and the rudder and stock may be supported solely by the casing for hung rudders in ships having sterns of the cruiser type.

Portable Electric Rivet Heating Devices

Electric rivet heaters in general embody advantages of cleanliness, ready movement from place to place in the shop and rapidity of heating. The United States Electric Company, New London, Conn., appreciating the

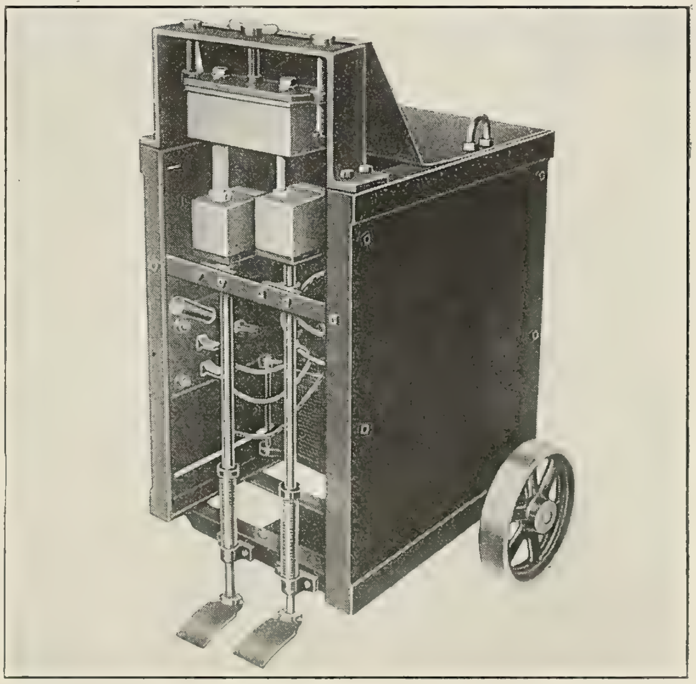

Fig. 1.—Rivet Heater, with Capacity for ¼-Inch to 1½-Inch Diameter Rivets

need for this equipment in boiler, railroad, and structural working shops has developed the rivet heating devices illustrated.

The heater shown in Fig. 1 has a capacity of rivets from ¼ inch to 1½ inches in diameter by 6 inches long. The time required for heating a rivet of the largest size is about 30 seconds.

The device is built in three types A, B and C with electrodes arranged to heat two, four or six rivets at one time. The large type C machine can heat twelve pin rivets per minute, which is as fast as they will ordinarily be required. Ten, 15 and 20 kilowatts, respectively, is the power consumption of the machines, depending upon the diameter of rivets to be heated.

A pan is supplied with the heater when it is desired to

hold a quantity of rivets in front of the operator or heater, and the rivets are easily placed by hand in the electrodes and removed with the tongs when heated. The operation is simple. The control switch being set for the size of rivets to be heated, the operator presses down on the foot lever and places a rivet between the electrodes until the desired heat is obtained. By heating in series after the first two rivets are heated, there is always a hot rivet ready for the riveter, and the operator always can control the current by removing one rivet, eliminating the pulling of a switch. The switch will be supplied if specified so that it will not be necessary to remove the rivet. The machine operates on 60 cycles and 220, 440 or 550 volts, single phase.

The automatic rivet heater, illustrated in Fig. 2, is built to heat rivets when making long runs on one size of rivet, heat-

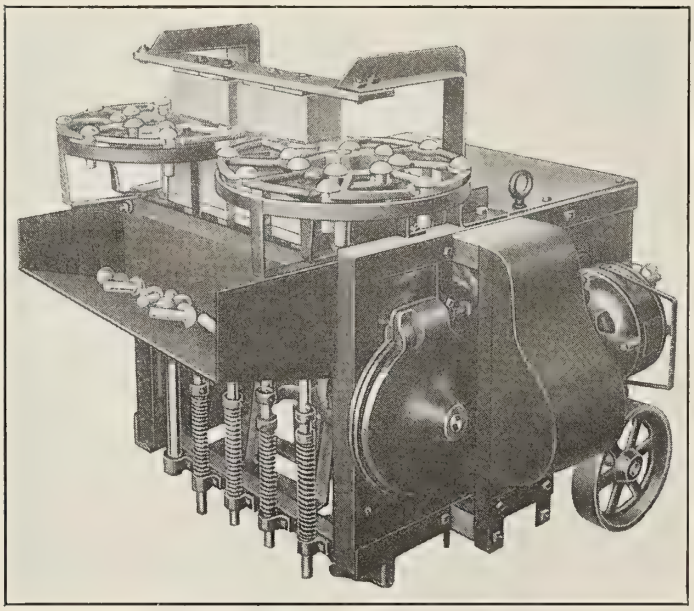

Fig. 2.—Automatic Electric Rivet Heater for Use When Making Long Runs on One Size of Rivet

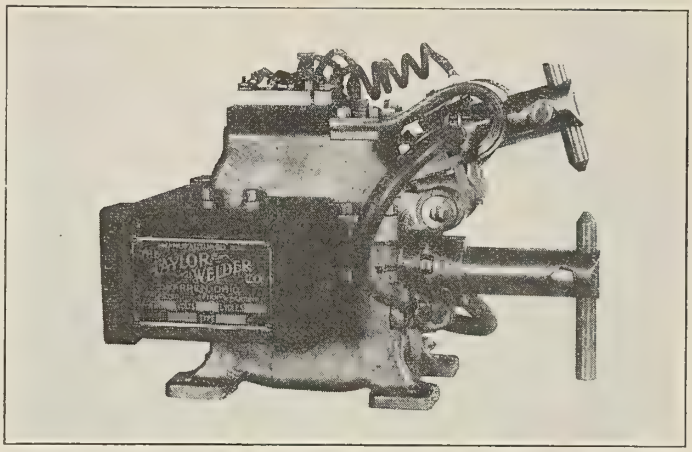
ing as high as 12 ¾-inch by 2½-inch rivets per minute. The machine is equipped with a control switch, the disks being arranged to hold any size rivet and accommodating 32 at one loading. The electrodes can be adjusted for any length of rivet up to five inches long and timed to give the desired heat in the rivet.

Bench Type Spot Welder

A NEW spot welding machine of the bench type, having a capacity of two pieces of No. 30 to No. 16 gage sheet metal, has recently been put on the market by the Taylor Welder Company of Warren, Ohio. The machine has a cast copper frame which acts as a secondary and adds to its efficiency. Two horns of cold drawn copper 1¼ inch in diameter protrude from the machine, the upper horn being capable of movement through a distance of one inch. The lower horn is made adjustable by drilling three sets of holes in the base and setting the horn to suit the work, a long electrode being furnished to meet this condition.

With the lower horn in its highest position the distance between the two horns is three inches. This distance can be increased to five inches when the lower horn is in its lowest position. The transformer has a capacity of 3 kilowatts and a 4-step regulator is used for adjusting the current. Cooling is effected by the circulation of water through both the upper and lower horns. The floor space occupied by the machine is 10 inches by 17 inches and the extreme height from the bench is 12 inches. An automatic single pole switch closes the circuit and the upper horn and contact point is brought



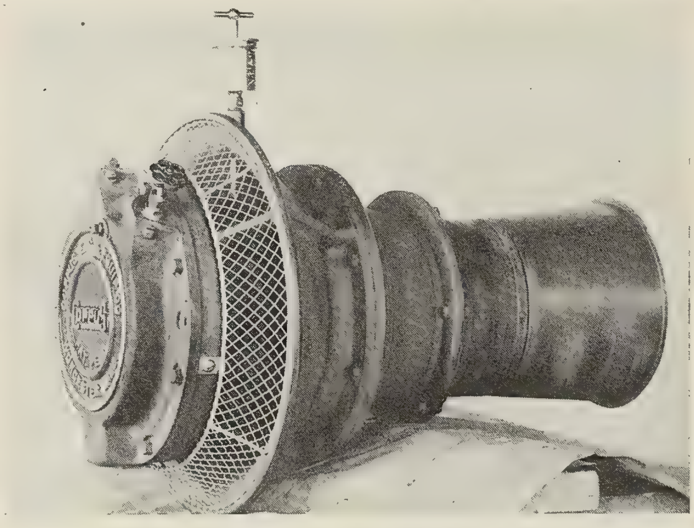
Bench Spot Welder with Water Cooled Welding Horns

against the work by the operation of a foot pedal, not shown in the illustration. The approximate weight of the machine is 150 pounds.

Blower for Forced Draft or Ventilating Service

SCREW blade propeller blowers which deliver air in lines parallel to the axis of the machine have been added to the line of blowers manufactured by the Coppus Engineering and Equipment Company, Worcester, Mass. The Coppus "Vano" blower is designed in two types for turbine and electric drive.

The principal feature of this blower is a stationary guide vane of special design located beyond the propeller. The individual guide vane blades subdivide the air current leaving the propeller radially. These blades, which have a curvature increasing in the direction of rotation of the propeller, concentrate the air current and give it an added



Turbine Drive Blower

acceleration inside the stationary guide vane so that a considerable part of the air pressure is produced in the vane. Much of the end thrust is thus taken up by the stationary guide vane casing.

Because of kinetic energy, the streams into which the flow of air has been divided by the guide vane blades rotate slightly and converge towards the axis as they leave the casing, so that the entire air flow is impelled beyond the guide vane.

The blowers are used for undergrate or forced draft service in hand fired boilers and also for ventilating purposes.

Cost Accounting and Estimating*

By H. H. Schulze†

Cost accounting and estimating are so closely allied that it is not possible to treat of one without the other. In early days, cost accounting as applied to ship work did not receive careful thought or attention but was considered more in the nature of clerical work; during later years, and especially since the cost plus form of contract came into being, cost accounting has become better understood and is today considered among the most important departments of the shipbuilding business. Cost estimating occupied much the same position as cost accounting, and few shipyards reduced their cost estimating to a systematic basis. It is therefore the intention of this paper to treat mainly of the second portion of the title and to describe the methods adopted in the effort to obtain uniform results.

THERE are really three main functions of cost accounting: First, for determining the profit; second, for submitting statements during construction to the operating manager, so that he can anticipate or investigate the overrunning of estimated costs; third, for estimating—that is, to determine the basis upon which to submit bids for similar work. The financial statements required for each of the above purposes are entirely unlike.

For determining profit but one figure is required, namely, the completed cost; for use of the operating manager the statement should be divided into groups corresponding with the division of his operating departments; for determining the cost for future work the statements should be divided by groups represented by physical quantities so that unit rates can be determined, to be applied to similar physical quantities calculated for the proposed work. A good accounting system should provide means to indicate all the above.

The number of groups in the accounting system depends largely upon the variety of work constructed. It is understood that, should but one type of commodity be constructed in which the relation of each operation to the other is always constant, but one factor would be necessary to determine the rates for similar commodities. In ship work, however, because of the varying relations of the many items and trades entering into the numerous types of vessels, it becomes necessary to subdivide the return cost into the correspondingly numerous items, which broadly may be classified in groups of hull and machinery.

The hull is usually divided into general items such as bonds, insurance, watching, temporary electric service, plans, trials and delivery; steel hull, including loft work, staging, launching, hull castings and forgings, and structural hull; woodwork, including joiner and carpenter work; also painting, hull piping, ventilation, electric work, steering gear, warping gear, boat gear, doors and hatches, airports, inside and outside fittings, handrails, deck covering, masts and rigging, and outfit. In naval work there must be such additional items as ammunition handling, turrets, installation of ordnance and armor.

The machinery is generally divided into main engine, condenser, pumps, boilers, stacks and uptakes, forced draft system, fuel oil system, piping, lagging, shafting, bearings, propellers, floors and gratings, tanks, and auxiliaries, including feed heaters, evaporators, distillers, oil coolers, auxiliary condensers, refrigerating, heating, fire extinguishing and disinfecting plants, together with tools and spares.

The above groups are more or less subdivided, according to the nature of the work constructed at the particular plant.

The return cost for each of the above items should be given in the three divisions: material, labor, operating expense, termed overhead.

Material is comprised of purchased material, *i. e.,* items requisitioned and purchased directly for a particular ship; and storehouse material, *i. e.,* material drawn from the general storehouse and applied directly to the vessel. The latter consists of such items as standard pipe, fittings, bolts, nuts, etc.

Labor, sometimes termed direct labor, is that portion of the labor which is charged directly to the vessel.

Operating expense, or overhead, consists of both material and labor and constitutes just as much a part of the cost as either the direct labor or material. It consists of material and labor which is more accurately distributed by prorating than by the direct charge.

The division between direct labor and indirect labor is by no means uniform at all plants. The general principle which determines the division is that direct labor should include all labor where little or no judgment is necessary by the operator in the division of his time. Where it becomes necessary for the foreman or quarterman to estimate the division of his time between the several vessels or jobs, such labor should be classified as indirect labor. An ideal system would be one where all the labor could be accurately distributed directly to its appropriate job. Unfortunately, much of the labor entering into ship construction cannot be charged direct without the arbitrary distribution by the employee, and it must therefore be included in the operating expense.

The material charges in the operating expense embrace such items as light, heat, coal, water, etc., and the labor includes the compensation of foremen, leading men, inspectors, clerks, messengers, cleaners, timetakers, etc. In addition to the above there is included, as administration, selling and general expense, a proportionate part of the cost of the office of the manager, sales department, treasurer, accounting department, purchasing department, plant engineers, service department, etc.

The distribution of the overhead in some businesses can be apportioned according to the units manufactured, where such units are all the same character, but in shipbuilding it has generally been customary to apportion the indirect expense as a percentage of the direct labor. Each department in the shipyard should have an account to which the expense of the department is charged, so that it may be possible each month to prorate the expense of that department among all of the direct labor which it performed for that period.

Since the distribution between the direct and indirect labor is not uniform at various shipyards, it can be seen that direct costs of one yard are not comparable with another yard. To make a proper comparison, it would be necessary to adopt not only a uniform cost system, but a uniform force report so that the distribution between the direct and indirect labor would be the same at all shipyards.

Cost estimates are prepared primarily to form the basis

*Paper read before the Society of Naval Architects and Marine Engineers, New York, November 18, 1921.
†Bethlehem Shipbuilding Corporation, Ltd.

of a bid or a selling price, and secondarily for the information of the general manager so that he may be advised what allowance has been made to each department so as to assist in the reduction of operating costs. The importance of the latter function is being recognized more and more, and an excellent paper on this subject, entitled, "How the Cost System Assists the Management in the Reduction of Operating Costs," was presented by Mr. William B. Ferguson, assistant to the president, Hog Island, before the Society of Industrial Engineers, on March 26, 1920.

Estimating

While the selling price is determined by the amount the consumer is willing to pay and the manufacturer willing to accept, few lump-sum contracts are taken without some form of estimate. The acceptance of a contract on a competitor's bid involves the dangerous assumption that the competitor has not made an error and that the purchasing power and manufacturing efficiency of both plants are equal.

The builder usually prepares his estimates on the same basis and, after submitting several bids, soon ascertains what allowance must be made over the estimates prepared by him to compete with other bidders. Thus, if he is consistently high, with a constant percentage as margin, he knows that, if he desires to obtain the contract, it is necessary to correspondingly reduce the amount of margin.

All estimating—in fact, the solution of all engineering problems—is performed by comparison. A formula is merely an expression endeavoring to reconcile by functions all the various conditions entering into the problem, and the closer the functions and formula represent the condition the more uniform will be the coefficients in the formula. The personal element in the selection of factors to represent the proposed condition is one of the reasons for erratic results in estimating.

Designing and estimating would be reduced to a more scientific basis if, under the given engineering condition, the same dimensions would be obtained at all times, irrespective of the person who is solving the problem. Again, after the size has been determined, if the same weight and cost would be obtained, then estimating would be reduced to somewhat of an exact science. The solution of this problem has been attempted by the method described herein, and, as far as it has been applied, has been found to be very successful.

There is usually a time limit to every estimate, and the problem is to make the best use of this time. One essential is to proportion the time according to the money value of the item, and another is to avoid repeat operations in every succeeding estimate. For example, it is unwise to devote a large amount of time to the calculation of structural foundations and then hurriedly figure the shell plating, merely because this portion is easy to calculate. Again, it is not desirable to devote a large amount of time to an intricate iron casting and to approximate the weight of a composition casting costing several times as much. Repeat operations are avoided by the standardization of particular items, as will be described below.

A good estimating system should be flexible enough to make the best use of all the particulars specified by the purchaser, and where these particulars are not specified it should provide means for determining the sizes according to the best standard practice.

Since estimating consists largely of a comparison with past practice, it is of importance that items to be compared should be on exactly the same basis; otherwise the estimator must make the proper adjustment in his mind before applying the new rates. In former years, when there was no great fluctuation in the material and labor market, it was sufficient to use the price-per-pound method for both material and labor, making slight modification as found necessary. When large fluctuation in material cost and labor rates occur, the mind cannot readily compensate for the varying rates, and comparisons with previous returned cost and with previous estimated costs become of no practical use; therefore a method should be adopted of placing all estimates on the same basis, viz., uniform base for material and labor rates.

Uniform Base for Material and Labor Rates

By an adoption of a standard schedule of material unit rates for the various commodities, and by reducing labor to hours, estimates can be placed on a uniform basis and would not only be comparable one with the other, but would also be available for use at any period by applying current rates to the quantities and to the labor hours which, combined with the current expense rate, produces an estimate on current rates. The relation of the current estimates to the standard estimate should be very nearly constant for the same period.

It is not alone sufficient that details be calculated accurately, but every estimate should be subjected to a check method to determine whether the total represents a reasonable figure. To accomplish this, resort is made to check summary cards, which indicate the quantities and costs combined in large groups, together with appropriate weight factors, and unit rates of material and labor.

The character of the estimate depends largely upon the character of the inquiry. Frequently inquiries do not give any particulars, and sometimes not even the general dimensions. This probably means that the prospective purchaser is merely feeling the market, and in such cases approximate estimates are prepared in condensed groups, using as a basis the check cards of the nearest similar vessels. In the hands of an expert with good judgment, such check-card estimates will give results which compare quite favorably with the detailed estimates.

While space will not permit describing in detail the method of determining the dimensions of vessels and their horsepowers to fulfil required conditions, it might be briefly stated that recourse is made to design cards bearing lineal ratios, displacement and weight co-efficients, also to the freeboard tables and to model experiments conducted by Admiral Taylor and Constructor McEntee. The freeboard tables have been reduced to curve form, making the determination of depth for any draft, length and extent of erections a very simple operation. By reducing the model results of Taylor's Standard Series to a mechanical operation and plotting curves of the relative performance of known models, the horsepower can be quickly determined, and with a reasonable degree of certainty.

In cases where only the general particulars are given, an estimate is prepared by the condensed groups without going into great details, except for the larger groups, such as structural steel hull.

When complete plans and specifications are submitted, or when it is probable that the prospective purchaser seriously contemplates construction, estimates are prepared in full detail. One of the first steps in preparing such detail estimates is the determination of the sizes of auxiliaries purchased from subcontractors and the submitting of the necessary inquiries. The subcontractor, before he will quote, will require complete information regarding the auxiliary, which necessitates not only the engineering knowledge for determining but also knowledge as to how this material is furnished by the subcontractor. In most cases the time required to prepare the estimate is governed by the time necessary to receive prices from outside contractors. This is particularly true when the auxiliaries are not of their standard manufacture.

Having briefly described the general principles and the several kinds of estimates, a description of the procedure in preparing a detail estimate will now be given.

Preparation of Detail Estimate

In a large company the work of estimating is divided among men who become specialists in their particular line. For instance, it is very desirable to have the quantities for woodwork, both carpenter and joiner, calculated by someone who has had practical experience in this character of work; piping should be determined by an expert piping man. The material is generally calculated in the same units as it is purchased—that is, steel by the pound, lumber by the board foot, floor covering by the square foot, etc.

The costs of construction bonds and insurance depend upon the time of construction and the amount of the contract and are estimated on this basis. The cost of the trial trip and delivery depends upon the horsepower, duration of the trial, size of the vessel and the point of delivery, and where this amounts to a considerable item a detail estimate is prepared, taking into account the consumption of fuel, lubricating oil, stores, number of crew, commissary, transportation charges, compass adjustment, docking, towboat charges, etc. In cases where it does not involve a considerable item the cost is merely based upon similar vessels.

The cost of plans is based upon the number of hours required in the drafting rooms, and it has been found that the best criterion for determining these hours is the total hours of direct labor for constructing the hull and machinery separately. Staging and launching depend upon the size of the vessel and the duration of the construction period, and, based upon these factors and the return cost of similar work, proper allowance is made for these items.

The weight of structural castings and forgings is calculated after the sizes have been determined from the registration rules. Practically all vessels are classified in one of the society rules, such as the American Bureau of Shipping, Lloyds, or Bureau Veritas, and if not classified, the scantling and sizes are usually obtained from the above rules.

Hull

The structural hull is by far the largest item of cost and weight in the vessel, and it is therefore essential that the quantities be determined with the greatest accuracy possible. Coefficient methods have at times been adopted, but the use of such methods is dangerous, particularly in the hands of the inexperienced or when a complete knowledge of their derivation is lacking. Usually the approximate lines are sketched, from which curves of shell expansion, floor areas, areas of bulkheads, decks, and the length of frames and reverse frames are obtained. From the above information and the scantlings obtained from the classification rules, quantities are calculated in detail. The grouping is always done in the same manner so that comparisons can readily be made. This is very essential and applies to other jobs as well.

The steel hull is calculated in three groups, each divided into regular classified subgroups. The first group consists of the continuous running members below the topmost structural deck, namely, transverse framing, longitudinal framing, keel plates, shell plating, inner bottom plating and decks. The second group consists of the other members below the structural decks and includes bilge keel, engine, boiler, and miscellaneous foundations, transverse and longitudinal bulkheads, chain lockers, shaft alleys and miscellaneous trunks and ducts. The third group consists of all the erections above the continuous deck, including structural work for the poop, bridge and forecastle, bulwarks, casings, etc.

The steel has been classified in the above logical groups in order that the result can be checked by coefficients obtained from similar work. The quantities are net weight, calculated in pounds, and are classified as to plates, angles, channels, bulb angles, half rounds, tees, etc. The net quantities are transferred to the cost sheets and due allowance made for wastage, to obtain the gross quantity or amount to be purchased. To these gross quantities current unit rates are applied, obtaining thereby the estimated purchase price of this material.

The labor on steel, as in all the other jobs, is estimated in hours, being based upon the returned hours on similar work; to these hours are applied the current averaged hourly earnings of the particular plant, giving the labor in money value.

Joiner work is calculated in board feet and necessitates a knowledge of the kind of materials and dimensions ordinarily used for carlins, studs, sills, plates, internal and external sheathing, straight and diagonal bulkheads and for the various items of furniture. Hardware, fastenings, glass, etc., are listed and priced, unless the time is insufficient, when they are taken by comparison with other work. As with steel, the quantities of lumber are transferred to the cost sheet, due allowance made for wastage, current unit rates of lumber are applied, giving the estimated cost of this material. The labor in hours is estimated, based upon the corresponding prices per board foot obtained in similar work.

Carpenter work is calculated in the same manner as joiner work, but, in addition to the number of board feet, lineal feet are calculated, since the labor is best applied on the basis of the lineal feet as laid by the carpenters.

The amount of paint is calculated in pounds, based upon the extent of the surface covered, treating separately the underwater body, the ordinary steel work, the joiner work and the varnishing and decorating. While cement amounts to a considerable item in the displacement, it does not involve much cost, and this is usually approximated, taking into consideration the size of the vessel.

The hull piping, including cargo oil mains, fire main, drainage and plumbing, is calculated in detail from a single line sketch plan made to suit the special requirements. The number and weight of flanges, fittings and valves are listed and the pipe is calculated in pounds, separate quotations being received for the plumbing fixtures themselves.

A similar procedure is followed in ventilation where this is an elaborate system; otherwise, the ordinary engine fireroom and hold ventilators are obtained by applying quantities derived from similar work. The costs of doors, hatches, airports, hand rails and deck coverings are obtained by counting, or calculating the number and size from the plans, and applying to the quantities, so obtained, prices and weights derived from similar work. After applying to such systems as steering gear, warping gear, anchor gear, boat gear, etc., the prices of auxiliaries received from the subcontractors, the remaining items are estimated by comparison with similar work. Masts, spars and rigging are calculated in detail—that is, the number of pounds of structural steel, the number, diameter and length of booms, the lineal feet of wire rope, the pounds of running rigging and the number and size of various blocks required.

The galley and deck outfit in some cases is very elaborate, and complete schedules are often forwarded to subcontractors for silverware, glassware, linen, bedding, etc., and these prices are applied.

Machinery

The machinery quantities are figured in detail and in the same units as the material is purchased. Within the time limit it is of course impossible to calculate the weights of each casting, such as cylinders, columns, bedplates, condenser heads, etc.; and in some shipyards the weights of such items are derived from an empirical formula, applying coefficients from the nearest similar work. For those shipyards which have a sufficient staff to enable weights and quantities to be classified and standardized, excellent results are obtained

with a minimum amount of time. Curves are developed for the various types of cylinders giving the weights for any diameter and stroke, one series for high pressure cylinders with piston valves; another series for intermediate pressure cylinders with one piston valve, with two piston valves, and with slide valves; and a similar series for low pressure cylinders with various types of valves. Similar curves are developed for all parts of the main engine, including bedplates, bearings, columns, guides, all items of the reciprocating group, the valve gear, etc., so that it is possible without detailed calculations to obtain the weights which meet the required engineering conditions. This same procedure can be adopted for all portions of the machinery estimates, including condensers, boilers, stacks and uptakes, shafting, bearings, etc.

One of the largest and the most difficult items in steam engineering is the steam engineering piping. The best procedure for calculating steam piping is to make a quick layout of the machinery with a single line sketch plan of the various piping systems, including main and auxiliary steam, main and auxiliary exhaust, suction and discharge piping, and to calculate from this layout all the valves, flanges, pipe and fittings in the same manner as for hull piping. Where the time limit will not permit of such detailed layout, piping is estimated in separate groups, as described above, by comparison with the nearest similar job; but here again great care must be exercised, since the several owners' requirements vary to such extent. One company might require copper pipe and composition valves for the system, whereas ordinary good practice would consist of wrought-iron pipe with cast-iron valves; and realizing that the former would cost several times as much as the latter it will be at once seen that the greatest care must be exercised in making assumptions in this group. The deck steam pipes, smothering pipes and heater coils for oil steamers sometimes consist of very large quantities, and, being comparatively simple, they are calculated separately.

Auxiliaries

The specifications cannot specify all sizes, dimensions and character of material, and therefore the estimator must have a complete knowledge of the character of the material and the size required for any portion of the machinery; for instance, in piping, it will be necessary for the estimator to know what connections are made to the various pumps, their size and character of piping. If the sizes of the condenser, air pump, and circulating pump are not specified, it will be necessary for him to know the best practice to determine these sizes. In reciprocating pumps he is required to know not only the size of the pumps, but whether they would be composition end, composition fitted, or with cast-iron cylinders—whether or not soft packing or metallic packing is required. The same detailed knowledge is required for determining all sizes and dimensions where not definitely specified. Having determined the net quantities, they are transferred to the cost sheet; due allowance for wastage, current unit rates are applied, obtaining the estimated cost of the material.

The labor, as with the hull, is estimated in hours, and in most of the groups is based upon the weight, though in some cases better results are obtained by applying unit rates, following the method of manufacture. Thus it has been found that in a condenser it is better to base the hours upon the number of tubes.

A summary of the hull and machinery is prepared from these detailed figures, and on this sheet is applied the current rate of expense. This is not constant for hull and machinery nor even for the separate jobs, since the expense rate of the various departments differ greatly, as described above.

The sum, then, of the material, labor and expense for the hull and machinery gives the estimated cost of the vessel. Throughout the process of estimating, check methods are continually applied, so that there is little possibility of a large error appearing in the process.

Standardization

To avoid repeat operations and to obtain uniform results, the various groups should be standardized. The general method of standardizing a group is, first, to ascertain the theoretical calculation by which sizes are determined; second, tabulate from practice the various sizes; third, apply the theoretical calculations and from practice obtain the coefficient so that the result may coincide with those usually adopted; fourth, calculate and tabulate results throughout the entire range of requirements. A few examples are as follows:

The size of the circulating pump depends upon the amount of steam to be condensed, the temperature of the sea water, the vacuum, and the percentage of the rated capacity of the pump in actual service. After having determined the amount of steam used by the various types of engines, the amount of water required by the theoretical calculation is determined and this amount compared with the rated capacity of the pump indicating that, in normal running condition, the pump is working at a certain percentage of its rated capacity. Tabular statements are then prepared for several temperatures of sea water and for predetermined water rates and vacuums for the several types of engines. Without calculation it is then possible to ascertain from this tabulation the normal size of a circulating pump for compound, triple, quadruple, turbine or electric drive, for several temperatures of sea water, the instructions giving the temperature to be used for the various routes.

The same method applies equally well to the hull jobs. In anchor gear, for instance, the size of the hawse pipe must be sufficient to prevent the chain shackles from fouling under all conditions. From practice, the clearance over the diagonal length of the chain shackle is plotted, to which is added the diagonal length of the shackle for determining the diameter of the hawse pipe. The length of the hawse pipe must be sufficient to permit of the proper housing of the stockless anchor. The top and bottom thicknesses and the dimensions of the lips are plotted from practice. With the standardized dimensions, hawse pipes are determined for all sizes of chains and the weights calculated. The dimensions of chain pipes, devil claws, cable clenches, hawse pipe covers and anchor davits are similarly determined and placed in tabular form. The weights and costs throughout the entire range are carefully calculated and tabulated, so that for any size vessel or any size chain the weights and standard costs of not only the above fittings but the windlasses, anchors and chains themselves can be immediately obtained either in detail or in total.

Application of Standardized Information

A brief description of the method of applying the standardized information is given by an example for determining the size of the main engine when not specified. A tabular statement is prepared, giving the minimum, normal and maximum horsepower; the size of the engine; the minimum, normal and maximum revolutions; together with reference plans, hull numbers, and condition of patterns for the various engines constructed, with intermediate sizes where the sizes constructed are not sufficient to cover the entire range of horsepowers. Based on propeller performance, a tabular statement is prepared, giving the normal revolutions for varying speeds and drafts. Following the direction of the typewritten instructions, it is merely necessary to ascertain from the latter table the normal revolutions for any given draft and speed, and from the tabular state-

ment of engines pick out the proper size. Reference is then made to a weight and cost folder for this particular size of engine, from which can be obtained at once the total net weight, the total gross weight, the standard cost of material and hours of labor. Current cost is obtained from the above by factors.

Similarly, the proper size of the condenser may be determined, and reference is made to the weight and cost folder which contains a list of condensers advanced by intervals of 100 square feet. This is accomplished by increasing or decreasing the length of the condensers actually constructed. The weights and costs are carefully calculated from bills of material, actual casting weights being used for gross weights and scale or calculated weights for net weights.

The principal weight factors for propellers are the diameter of the tail shaft, diameter of propeller, and area of developed surface. In determining the developed surface, the indicated thrust-per-square-inch method was adopted, using the information as published by Admiral Dyson, together with the actual practice used on merchant ships.

Similar methods can be applied to nearly all other jobs, such as forced draft systems, boilers, stacks, uptakes, lagging, shafting, auxiliary condensers, feed water heaters, refrigerating plants, and even tools, instruments and spares.

While the machinery jobs lend themselves better to standardization, similar methods may be applied to the hull jobs, and a few of these will be described.

The determination of the weight of the structural hull resolves itself into two operations: First, the determination of surfaces and lengths according to the dimensions and model; second, the determination of unit weights for those surfaces and lengths. The surfaces and lineal dimensions can be determined directly from a series of standardized lines somewhat similar to those described in the very instructive paper by Mr. A. J. C. Robertson, appearing in Transactions of 1920. These standardized lines were developed by making use of the experiments of Naval Constructor McEntee appearing in the Transactions for the year 1919, and also from the various other model experiments. Investigations were also made regarding wetted surface formulæ in order that the wetted surface for any particular model could be quickly and accurately determined. Taylor's formula was adopted as being the simplest formula, the accuracy being dependent only upon the accuracy of the coefficient. A series of curves of coefficients has been developed so that for any length, for any breadth, for any draft, and for any block coefficient, the surface coefficient could be obtained within the desired degree of accuracy.

The results of the standardization of lines have been incorporated in a folder with typewritten instructions so that a complete set of lines can be at once drawn up for any condition without fairing, or that a particular cross section can be obtained without the use of a set of lines; also, that the areas of any particular cross section to any height and the girths of any cross section to any height can be obtained without the necessity of drawing lines or that the entire surface can be obtained by a simple calculation.

The unit weights are established by the classification society under which the vessel is constructed, and tables of coefficients have been established for laps, rivets, etc.

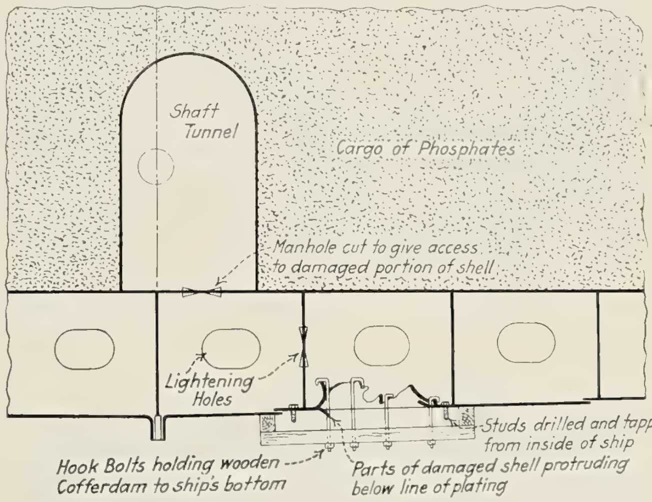
In joiner work standard drawings are made for the various items of portable furniture, such as berths, lockers, transoms, etc., and the number of board feet of lumber of various kinds, together with the amount of hardware for each of these items have been tabulated. The various kinds of bulkheads and joiner decks have been standardized for dimensions and the quantities reduced to lineal or square foot basis. The quantities for complete pilot houses and rooms for the various officers have been tabulated, so that it is unnecessary to make these detailed calculations for each estimate.

The work of standardization is performed during the intervals between estimates, and, when once started, the time saved on jobs already standardized can be utilized for further standardization. It is believed that the time-saving element and the uniformity and accuracy of results well warrant the labor expended; certainly, after the standardization is complete, the time required to prepare an accurate estimate is very much reduced.

A Difficult Submerged Repair Job Accomplished

By A. C. Waters*

THE Japanese steamer *Tamon Maru VIII,* which recently bunkered at Newcastle, Australia, had the misfortune when about to leave port to rip a hole in the bottom of her after ballast tank on a submerged anchor. The *Tamon Maru VIII* is a vessel of 2,977 gross tons, 327 feet long, 41 feet beam and 26 feet depth, and at the time



Sketch Showing Extent of Damage to Bottom of S. S. Tamon Maru VIII

was carrying a full cargo of phosphates. The extreme dimensions of the hole were approximately 4 feet 6 inches square.

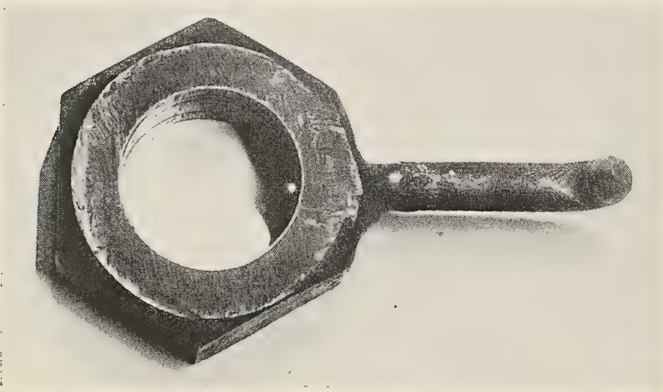
There is no dry dock at Newcastle, and, even if there had been, it would probably have been necessary to unload at least a portion of the cargo, which would have been ex-

*Shipyard manager, Government Dockyard, Newcastle, Australia, N. S. W.

View of Cofferdam on Deck

pensive quite apart from the fact that available wharfage space would have been difficult to find.

It was therefore decided to make the repairs while the vessel lay alongside the dolphin, and the Government Dockyard at Newcastle was invited to undertake the job. The work was started September 23 and the vessel was able to

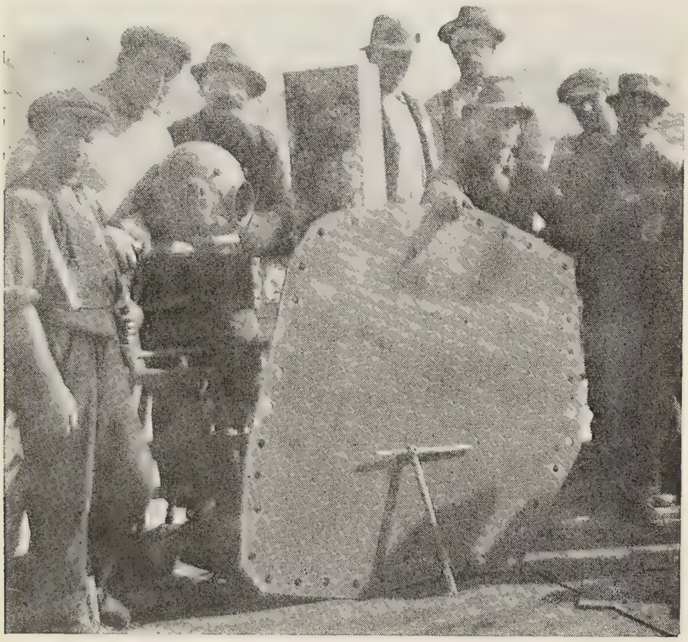


Clearance Nut for Locating Position of Stud Holes

leave port October 1, carrying Lloyd's certificate permitting her to travel to any part of the world.

The work was accomplished as follows:

A large heavy cofferdam, about 6 feet square, was first secured by hook bolts to the damaged portion of the shell by the diver. The after ballast tank was then pumped out, after which a temporary manhole was cut through the tank top in the tunnel, as the regular manhole entrance in the hold was covered with tons of cargo. The work of taking away the damaged portion of the plate, and tapping and fitting of ⅞-inch studs was all done inside the ballast tank



View of Patch Used to Repair Bottom

and within the boundary of this cofferdam; a risky performance, but the good job made by the diver allowed only a little water to enter the tank.

When all these studs were in place and the patch was taken account of from the inside, the manhole cover was secured in position and the diver sent down to demolish the cofferdam. A template prepared in accordance with the information taken from the inside of the vessel was then sent down with the diver. The holes in the template were large enough to easily fit over the ends of the studs. A clearance nut, as shown in Fig. 3, was given the diver and, by describing circles with this nut about the ends of the studs, the exact position of the center of each hole was obtained for punching the plate. This system of obtaining the exact position of each hole worked out so well that, although the plate was punched with proper sized holes and first shipped over the two long pilot studs, it went over the remainder of the studs at first trial, and was screwed up by the diver in very short time, the diver taking all he could on the bolts as the outside pressure increased during the pumping out of the tank. The nuts were further secured by upsetting the ends of the studs.

When the tank was pumped out, examination from the inside showed that the patch was absolutely dry, not even showing signs of a weep. The extreme dimensions of the patch were about 4 feet 6 inches by 4 feet, and it was secured to the shell of the vessel by ⅞-inch studs about 4 inches apart. The patch was ½-inch thick, and after inspection was covered by about 4 inches of cement, which thickness existed elsewhere in the tanks.

It might be added that the remaining portion of the damaged plate served as an excellent holding power for the cement, and the whole job is considered as being very strong and effective, Lloyd's surveyor passing same to allow the vessel to steam between any ports without docking.

Oil Tanker Fulgor

THERE was recently launched by the "Cantieri Navali della Spezia," Spezia, Italy, the tanker *Fulgor* built to the order of the Società Marittima "La Columbia," Genoa, Italy. This tanker is intended to carry oil in bulk between the different ports of the North American Atlantic coast, the Mexican Gulf and also the Black Sea ports, supplying Italian and African ports on the Mediterranean coasts.

The principal dimensions of the vessel, built on the Isherwood system, are as follows:

Length between perpendiculars	401 feet 11 inches
Breadth extreme	54 feet 9 inches
Depth molded	31 feet 3 inches
Gross tonnage	about 6,500 tons
Load deadweight	9,000 tons

The propelling machinery, main and donkey boilers and auxiliary machinery have been supplied by Messrs. McKie & Baxter, Govan, Glasgow.

The propelling machinery consists of one set of quadruple expansion engines, balanced on the Schlick-Tweedy system, with cylinders 21 inches, 29½ inches, 43 inches and 62 inches diameter with a stroke of 45 inches designed to develop about 2,000 indicated horsepower to give the vessel a sea speed of 10 knots.

Steam is supplied by three single ended Scotch boilers fitted to burn either coal or oil, with Howdens forced draft and White low pressure oil fuel system. Steam for the deck machinery is supplied by one single ended Scotch boiler also fitted to burn either coal or oil.

The following auxiliaries are provided: one steering gear, by Donkin & Company, Ltd., Newcastle, one windlass with capstan, two winches, two main petroleum pumps, two auxiliary oil fuel transfer pumps, two dynamos, one Hall's refrigerator, two evaporators, one fresh water distiller and all other auxiliaries for the main engine.

A sister ship of the *Fulgor,* named *Vigor,* is also being built at the same yard.

The Shipping Board announced on March 9 that it has fixed a minimum price of $30 a ton for its ships as representing the world market price and has sold a number of ships at this figure.

Deck Coverings—II

By Horace Holden Thayer*

Continuation of a series of articles containing information regarding shipbuilding materials and their uses that is not readily obtainable from shipbuilding handbooks and other generally available sources. The articles are not intended to be a complete exposition of the subject but will be found to contain items of value to the various classes of workers in this field who have to deal with these materials from the materials point of view.

COMPOSITION deck covering when well made is not subject to as much expansion and contraction as cement deck covering. It is the practice on large surfaces to insert expansion joints about 30 feet apart, filling them with an asphalt of high melting point.

Expansion and Contraction

There are three types of expansion and contraction effects—the first, that due to expansion with heat and contraction with cold, the second, that due to setting reactions, and the third, that due to aging or storing conditions, humidity, etc. The first of these is very small, but expansion and contraction due to the other causes is sometimes comparatively very great and leads to grave trouble in many cases.

The majority of the expansion or contraction effects of composition deck covering usually occur during the period between final set and 24 hours old. Some products show an expansion of .3 percent in this early period and some a contraction of like amount. With the latter cracking is sure to occur and the former will often cause buckling.

All composition deck covering of the usual mix will expand in moist air or when wet, regardless of the type of magnesite used, but it will not always contract in absolutely dry air.

Some magnesites expand when stored in normal air and some contract. Both the chemical composition and the burning temperature influence the expansion and contraction, but this influence has not been clearly defined. It is unfortunate that commercial magnesites vary as much in this respect as they do, for there is little doubt that much of the trouble encountered by deck covering manufacturers is traceable to this cause.

Excessive amounts of chloride increase expansion effects.

As is the case with strength and wearing resistance, the amount of expansion or shrinkage is dependent upon the strength of the chloride solution used. With expanding magnesites the 22-degree solution is the one productive of the best results, while shrinking magnesites admit of greater solution strengths.

Kieselguhr, Celite, precipitated chalk, volcanic ash and other materials which are of an impalpable fineness, when used in place of silex, are almost certain to give a cement having an excessive tendency toward shrinkage and cracking. Such aggregate absorbs a larger volume of solution and this in drying out during setting produces a change in the volume of the mass. This nullifies the value of the increased covering power sought for and made possible by the use of Kieselguhr and similar materials.

Watertightness

Properly made composition deck covering when intact is practically watertight. Tests on a sample one-half inch thick, as reported by one of the leading exponents of this type of decking in the April, 1918, issue of this magazine, showed a water absorption of less than 2 percent of the original weight after the sample had been submerged for four weeks. Although this type of deck covering as at present developed is essentially an interior one and not suitable for continuous wetting, it is important that it allow of frequent washing without disintegration, that it be unaffected by water standing on it for a reasonable length of time and that it shall not allow water to penetrate to the steel deck beneath it.

The principal factor in securing watertight qualities is proper grading. Some commercial products are so porous, due to improperly graded aggregates, as to allow of seepage of water through them.

The use of too great an amount of water absorbent aggregate, such as soft wood sawdust or flour, impairs the watertight properties.

There are various solutions on the market designed for integral waterproofing, which are of some value. They are, however, not necessary for the customary service of a properly made composition deck covering and cannot be expected to make up for the defects of an improperly made one.

Setting Time

Magnesium oxychloride cements are subject to two sets, an initial set and a final set. After the composition deck covering is mixed, dumped upon the deck and leveled off, the workmen have to wait for the initial set to allow them to move about on it without displacing it for the purpose of surface trowelling. When final set takes place no more trowelling can be done and, if it takes place too soon, the surface has to be finished off as well as it can be by the use of wire wool. There should manifestly be a reasonable time, depending upon the size of the job, between the mixing of the materials and the initial set and at least two hours between the initial set and the final set. With a properly made composition both times are ample and there will usually be about six hours between the mixing and final set in the hot summer months, increasing to about 48 hours in cold winter weather. Composition does not freeze at a temperature higher than 50 degrees below zero; so there is no interruption of operations on that score.

The setting time increases rapidly with decrease of temperature below the normal and decreases very materially with increase of temperature above the normal. The Dow Chemical Company has prepared a curve to show directly the setting time of any oxychloride flooring at any temperature, if its setting time at the normal temperature, i. e., 60 to 70 degrees, is known. This curve shows the setting time at 35 degrees temperature to be about 3½ times that at 70 degrees, and the setting time at 100 degrees to be slightly over one-half that at 70 degrees.

The Dow Company has also prepared curves for use in estimating the effect of chloride solution strength on the setting time, provided the setting time with the use of any definite strength of solution is known, other factors remaining the same. These show for deck covering mixtures an increase in the time after mixing the material required for both initial and final set as the chloride solution is increased from 16 to 26 degrees Baumé, and show that the time between the two

*Member of the firm of Rossell & Thayer, naval architects and marine engineers, Philadelphia, Pa.

sets is a minimum with the 20-degree solution, increasing both ways from that point. They have found that the setting time of an oxychloride cement will average 10 percent faster when made up with 18-degree solution and 10 percent slower with a 26-degree solution, than when a 22-degree solution is used.

The initial set is but little affected, though in some cases hastened by damp air, but the final set is slower in such air. Eight samples of flooring mix tested by the Dow Company in 1920 showed an average of only about 12 minutes increase in the interval between initial and final set with moist air as against normal air when mixed with 18-degree magnesium chloride to normal consistency at normal temperature and about 30 minutes increase in the interval between initial and final set with 22-degree solution.

Both initial and final set occur later as the stiffness of the mixture is decreased from the normal value. The writer has no data for deck covering mixtures to show clearly whether the elapsed time between the two settings is increased or decreased as the product is thinned.

The greater the amount of magnesite, the earlier will be the initial and final sets; but no appreciable gain in the interval between the two sets can be obtained by varying either way from the normal amount.

Magnesite that is underburned sets earlier and magnesite that is overburned sets later, in the composition, than the normal. Many commercial magnesites are far too rapid setting for use in hot weather. Twelve samples of a number of different commercial magnesites made up into a deck covering mixed to normal consistency with 22-degree solution were found by the Dow Company to have initial sets in from 1½ to 6¾ hours, final sets in from 3 to 9¼ hours, and differences between initial and final sets of from 1¼ to 2½ hours. These results show the lack of uniformity in commercial magnesite and the necessity for careful physical tests of the magnesite shipments. Specifications calling for a minimum setting time at a particular temperature would be of great value.

Calcium chloride and sulphates as impurities in the magnesium chloride will somewhat increase the time between initial and final set. These with salt constitute the impurities for which the magnesium chloride is usually tested. The salt has no effect on the setting time.

Color

Uniform and permanent colors can be obtained in Venetian red, dark red, brown, tan, yellow, gray green, light gray, dark gray, white and black. The first mentioned is the most usual probably because being the easiest with which to obtain lastingly good results; and it is a good, warm color for shipboard use. Blue is not apt to be permanent, being affected by any weak acid that might come in contact with it; and a true green, unless made with very expensive material, will in time be changed to yellow.

Thorough mixing is of course a factor in color uniformity.

The Dow Company suggests improving the color uniformity by suitably coloring the fibrous aggregate used; but aniline colors are apt to change color when the magnesium chloride solution strikes them and oil colors will gum the fibers together. Perhaps, however, something of this kind can be worked out.

The surfacing tools used sometimes mar the color. Iron trowels are blackened by the chloride solution and frequently smear the surface when first used on later work. Brass and copper trowels produce a green discoloration from the same cause. This trouble may be eliminated by the use of bronze trowels.

Sweating and Efflorescence

Sweating of the composition deck covering results principally from an excess of magnesium chloride solution, which absorbs the moisture from the air. It depends to some extent upon the nature of the magnesite used. Some magnesites are hard and sandy in texture even though finely ground while others are soft and velvety. The former have a tendency to allow the solution to work to the surface during trowelling while the latter hold it uniformly in the mass. An excess of surface chloride combines with the other surface material to form a compound which is very hygroscopic. Underburned magnesites combine with much less chloride than do properly burned magnesites, and may on that account give rise to sweating troubles.

Efflorescence is principally a result of the sodium chloride, or salt, which occurs as an impurity in the magnesium chloride, and less than .2 percent of salt will cause it. It is increased by heat. If it is not washed off as it appears it has a tendency to fade the color of the deck covering. Efflorescence is only a temporary trouble and a flooring that is kept clean soon loses this undesirable property.

Surfacing

The surface finishing of a composition deck covering is a very important factor in a successful installation, and necessitates the maintenance of a field organization of workmen who are skilled in the art.

The use of fine fibers and wood flours is an aid to ease of trowelling and the uniform appearance of the deck covering. The value of trowelling as an aid to wearing qualities and the reduced wear resulting from the use of wood flour instead of sawdust have been previously referred to.

Cork as an aggregate has a tendency to cause roughening and pitting of the surface under traffic. It has been tried out in various forms by some of the deck covering manufacturers, and abandoned.

Imperfect mixing results in surface pitting.

Thickness of Coating

The properties of a composition deck covering, among which are relatively slight toughness and some expansion and contraction, demand a minimum thickness over buttlaps or other high spots of ¾ inch. The thickness of 1½ inches which is usually specified for shipyard work will in most cases allow of this. The average thickness of such a covering will be about 1⅛ inches, and the weight may be approximately figured as 7¾ pounds per square foot.

Specifications

The writer has not seen any specifications for composition deck covering that properly protect the user of it, and this is probably because any batch of material cannot be properly tested out prior to being put down and because the test of a previously prepared sample or of a part of another batch will not give the answer. It is probable that most of the technical points which we have been considering will have to be taken care of by the manufacturers in specifications for the purchase of their materials, and the writer understands that the National Association of Oxychloride Cement Manufacturers is about to undertake the preparation of revised and uniform specifications of this nature. The following requirements can however be very well embodied in specifications for the completed product:

1. The application of an approved bituminous solution directly on the steel.
2. Pure ingredients of the nature required for a magnesium oxychloride cement, properly graded.
3. Uniform and permanent color.
4. Thorough mixing of the ingredients.
5. Use of magnesium chloride solution strength not less than 22 degrees Baumé.
6. A consistency of mix that will support on end a 1-1/4 inch diameter blunt ended rod weighing 250 grams.
7. An approved method of binding the covering to the deck.
8. A normal thickness of 1-1/2 inches or more, as desired, with a minimum thickness at any spot of 3/4 inch.
9. A thoroughly trowelled, smooth surface.
10. A guarantee for one year against excessive wear and cracks.

The guarantee does not protect the ship from loss on account of being delayed while the covering is being renewed, but is of value when furnished by a reliable manufacturer.

Congoleum

See "Felt Base Deck Covering."

Cork Composition Tiling

This is an interior deck covering made of powdered cork, wood flour, linseed oil, gums and pigments, in a manner similar to linoleum and cut into tiles which finish about ¼ inch thick, interlocking or otherwise.

It is quiet, warm, elastic and non-slippery to the tread, has good wearing qualities and allows of pleasing artistic effects. It is used in the same locations as rubber tiling. This tiling ¼ inch thick weighs about 1½ pounds per square foot. It is cheaper and lighter than rubber tiling.

The materials should be clean and pure and thoroughly mixed so that the tile is homogeneous throughout.

The sheets should be seasoned in drying rooms for at least three months before the tiles are cut. The edges should be cut clean and square, and the tile be true to size, as otherwise the covering could not be laid watertight.

The tiles are fastened to the backing with waterproof cement and should be serrated on the under side to insure a proper bond with the backing. They can be laid direct on wood or cement. Steel decks are preferably leveled off with a special cement or composition as Portland cement will crack under this tiling unless it is several inches thick. A coating of bituminous solution under composition is desirable.

Dreadnaught Tiling

See "Cork Composition Tiling."

Duraflex

See "Mastic."

Everlastic Tile Decking

See "Cork Composition Tiling."

Felt Base Deck Covering

This deck covering is a substitute for linoleum. It is proposed by its manufacturers for use in the same locations and is laid in the same manner. It is an asphalt saturated felt base material, and, if a poor asphalt is used, the product will be poor. The following specifications have been prepared by one of the manufacturers as embodying requirements which will ensure good quality.

Base Material and Seasoning. The base of this material is to be manufactured of a good grade of rag stock well beaten and formed into a sheet and then staurated with compound petroleum asphaltum. This saturated sheet shall then be well seasoned before the application of any surfacing material.

Surface Material. The surface of this material shall be manufactured of the best grade of linseed oil, gums, pigments, and colors. It shall be well baked and thoroughly seasoned before inspection and shipment.

Uniformity of Color and Grain. When this material is cleanly cut at an angle of 45 degrees, it shall show no material difference in color or grain between the edges and center in either the base or the surface.

Weight and Thickness. The thickness of the base of this material shall be measured on a spring micrometer thickness gage, and shall gage between 63/1000 inch and 67/1000 inch. The surface of this material shall also be gaged on a spring micrometer thickness gage and same shall gage between 26/1000 inch and 29/1000 inch. This material finished shall weigh five pounds to the square yard and shall have a total thickness of from 90/1000 inch to 96/1000 inch.

Backing. The back of this material shall be well covered with a coating of linseed oil and pigments.

Tests for Quality. This material shall be made to withstand the following tests after it has been kept at a temperature of 70 degrees F. for a sufficient length of time so that the whole body has reached this temperature.

Bending Test. A strip 2 inches wide with backing on inside of curve shall bend, without showing the slightest signs of cracking, around a bar two inches in diameter. At least one strip shall be cut longitudinally and one strip transversely of the roll.

Indentation Test. This is the same as required by the Navy Department for linoleum and given later under that head.

Absorption Test. A sample 6 inches by 3 inches shall be weighed and then submerged for 24 hours in fresh water at a temperature of 70 degrees F. The sample at the end of this period shall be removed from the water and the surfaces, including edges, dried between blotter or filter paper. At the end of 2 minutes from the time the test piece has been removed from the water it shall be weighed again. The increase of weight shall not be more than 5½ percent.

Number of Tests. When inspected at the factory, at least one complete set of tests shall be made on each lot, a lot being defined as material submitted for inspection at one time, made of the same quality and proportions of saturating material and coloring matter, calendered and seasoned at the same time and under the same conditions. In no case, except in the delivery of a single roll, shall less than two sets of tests be made.

Insulite Mineral Rubber Flooring

See "Mastic."

J. M. Asphalt Flooring

See "Bitumen Deck Coverings." Class (b) Trinidad asphalt is used.

Kompolith

See "Composition."

Lead

Sheet lead should be used on wood decks under the entire cement floors of wash rooms and toilets, extending up the side walls about 9 inches above any other deck covering. Sheet lead around a room extending up on the walls in this manner and a short distance out on the floor is called a flashing; and lead flashings should be run generally around toilet and wash rooms which are not tiled, refrigerated rooms and other spaces on the floors of which water is apt to collect. Lead is sometimes used on the floors of wash rooms with no other covering except a wood grating.

Sheet Lead for these purposes should be about ⅛ inch thick, which weighs 7.4 pounds per square foot.

Linoleum

Linoleum is an interior deck covering and the nature and properties of the inlaid, or so called "Battleship," linoleum are similar to those of cork composition tiling. It is of value for the wheel house, chart room, living quarters and passageways. Navy Department specifications for this material embody the following requirements:

Material and Seasoning. To be manufactured from the best grades of linseed oil, driers, gums, cork and coloring matter. An admixture of wood flour is not objectionable, provided that the requirements of these specifications are met. It shall be thoroughly seasoned before being offered for inspection or before being shipped.

Uniformity of Color and Grain. Surface cleanly and freshly cut at an angle of 45 degrees shall show no material difference in color or grain between the outer edges and the center. To be terra-cotta red ground body throughout.

Cork. The cork shall be clean, thoroughly ground, and of such size that when ready for use it will pass through a screen not coarser than 22-mesh.

Burlap Backing. The linoleum compound to be provided with a burlap backing of the best quality of hard-spun yarn weighing not less than 8 ounces or more than 11 ounces per 36 inches by 40 inches. The burlap to be deeply imbedded and keyed to the cork compound so as to be partially concealed in same. The burlap shall not be painted.

Weight and Thickness. Thickness shall be measured over the burlap on a spring micrometer thickness gage. The grades of linoleum shall be known as "Heavy," "Medium" and "Light," and shall conform to the following:

	Thickness in inches		Weight per square yard in pounds
	Minimum	Maximum	Minimum
Heavy	0.243	0.265	9½
Medium	0.185	0.201	7
Light	0.125	0.142	5

Tests For Quality. Linoleum shall withstand the following tests after it has been kept at a temperature of about 70 degrees

F. for a sufficient length of time so that the whole body of the linoleum has reached this temperature.

Bending Test. A strip 2 inches wide with burlap on inside of curve shall bend, without showing the slightest sign of cracking, around a bar 3 inches in diameter for heavy, 2½ inches in diameter for medium and 2 inches in diameter for light weight linoleum. At least one strip shall be cut longitudinally and one transversely of the roll.

Indentation Test. Sample disks, 1 inch in diameter, shall be cut from the delivery and prepared by removing the backing and then buffing so that the under surface is absolutely smooth and parallel to the upper surface. A pressure of 80 pounds shall then be applied to the upper surface of the disks for a period of 60 seconds by means of a flat cylindrical steel bar 0.282 inch in diameter. The bar shall be supported in a frame in such a way as to insure the face of its foot being parallel to the surface of the linoleum. The edges of the face by means of which the pressure is applied shall be buffed smooth to prevent cutting the linoleum. The load shall be lowered gently until its entire weight presses upon the linoleum, but in no case shall the load be dropped upon the linoleum. One hour after the test has been made, the depth of the indentation shall not exceed 0.010 inch. If the depth exceeds this amount, the material shall be rejected. The surface of the material shall show no sign of being broken through or cut and, if such condition exist, even though the depth of the indentation does not exceed 0.010 inch, the material shall be rejected.

Burlap Test. Two-inch strips of linoleum shall be taken, one in the direction of warp and one in the direction of filling, and broken about 1 inch from the end by cutting part way through from the face and bending back. The burlap backing shall then be stripped slowly from the remainder of the test pieces by pulling at right angles to the back. The pull required shall not be less than 6 pounds.

Absorption Test. A sample 6 inches by 3 inches, prepared by removing backing and sandpapering or buffing the rough surface from which the backing is removed until the surface is absolutely smooth, shall be weighed and then submerged for 24 hours in fresh water at a temperature of 70 degrees F. The sample at the end of this period shall be removed from the water and the surfaces, including edges, dried between blotter or filter paper. At the end of 2 minutes from the time the test piece has been removed from the water it shall be weighed again. The increase of weight shall not be more than that indicated in the following table:

Linoleum	Allowable increase of weight
Heavy	3½ percent
Medium	5½ percent
Light	7½ percent

The wear resisting qualities of inlaid linoleum as well as the very inferior nature of painted linoleums are illustrated by the wear resistance table in the section on "Composition."

When laying linoleum all inequalities should be filled up with a special cement and the deck and the underside of the linoleum coated with linoleum cement.

Linotile

See "Cork Composition Tiling."

Linotol

See "Composition."

Litosilo

See "Composition."

Maple

This is an attractive deck covering that is of value on shipboard for public rooms of the nature of social halls. Its good wearing qualities are shown in the table in the section on "Composition."

Maple decking should be quarter sawed, ⅜ inch by 1½ inch, and be laid over a substantial wood deck with a layer of parchment sheathing paper between.

Marbleloid

See "Composition."

Maritimo

See "Bitumen Deck Covering." Special.

Mastic

The name Mastic is usually applied to a deck covering that is made by dissolving Elaterite by a volatile oil in sealed containers and adding asbestos fiber. Elaterite is a mineral rubber found in Utah which is almost pure bitumen and has a melting point of about 300 degrees F. The more volatile the oil the better, hence naptha is generally used. When applied to a deck the naptha evaporates, leaving a firmly adherent coating that contains no material soluble in water or acids, nor anything injurious to steel.

Mastic is resilient, waterproof, sanitary, durable and of light weight. A proper installation will not crack or come loose from the deck plates. If it is scarred or otherwise damaged it is very readily repaired; and holes can be cut in it or work done to steel or woodwork beneath it without injury which cannot readily be made good. Worn spots can be patched and the patches made indistinguishable from the original. It is much preferable to cement for living quarters, such as for the ship's personnel, where the cost of composition might not be warranted. The colors most readily available are black, green and dark red. An effort to obtain other colors would probably be at the expense of some of the good qualities of the coating.

For a substantial coating there should be a minimum thickness of at least ⅛ inch which for best results requires four coats. The naptha will not evaporate properly from a coat much over 1/32 inch thick and an attempt to lay thick coats results in a covering which will harden on the surface and be soft underneath, thus becoming dented and uneven. Inequalities in the surface to be covered, such as plating laps, are taken care of by previously prepared wedges of the material or some other material such as composition which will not crack or have a tendency to creep in hot weather.

This deck covering will weigh from 2 to 3 pounds per square foot, depending upon the inequalities in the surface to be covered.

The chief disadvantage of Mastic is the fire hazard due to the evaporating of the naptha while the material is being laid. A light of any kind or even a hot rivet will start a fire. There is no danger after the covering has hardened. This objection could be overcome by the use of tetrachloride of carbon instead of naptha to dissolve the Elaterite, but that material is very expensive. It can be said in this connection that while some shipyards will not use Mastic on account of the fire hazard, it was used during the rush work of the war on a great many steamships without any fire casualty as far as known to the writer.

In laying Mastic on a steel deck a coat of liquid gum solution is applied, the triangular filling pieces at the laps and butts are laid in it, and the first body coat of Mastic is put on with a trowel in a plastic state and then rolled, without any waiting between these operations. Other body coats and the finish coat are laid on subsequent days, one a day. Sometimes two finish coats are required. The body coats get hard enough to walk on in about 12 hours, and the finish coats, which have the color in them, in about 24 hours, though this depends somewhat upon weather conditions.

Mastic is laid on wood and concrete decks in the same way except for the absence of filling material to level up these decks.

Neuchatel

See "Bitumen Deck Covering," Class (b).

Penco

See "Composition."

Rubber Tiling

This is an ideal deck covering for dining saloons, smoking rooms, lobbies, passageways in passenger accommodations, stair treads and similar service. It has the well known quiet, resilient, non-slippery and waterproof properties of rubber, and admits of artistic design and coloring. The tiles are made interlocking or otherwise, about ⅜ inch thick, and are cemented down. They are usually made up in sections 2½ feet square for convenience in laying, composed of a number

of the tiles locked together in the desired pattern. The backing has been referred to in connection with cork composition tiling.

Rubber tiling is more expensive and heavier than cork composition tiling but on the other hand it is more waterproof and sanitary and has a cleaner appearance. The weight is about 4½ pounds per square foot.

Tenax

See "Bitumen Deck Covering," Class (b).

Tile

The two classes of tile which are of particular interest for shipbuilding purposes are—

(a) Wall tile
(b) Floor tile

Both are usually ceramic, or pottery tile, made of powdered clays which are subjected to great pressure and fired. They are given an uneven back surface for better adhesion to the backing material.

The wall tiles are mostly made of white-burning clays and flint and are porous and of moderate hardness after being burned. These tiles are, however, subsequently dipped in a glazing mixture and fired a second time, which develops a hard, waterproof surface that is very sanitary and easily kept clean.

The floor tiles, with which we are principally concerned, should not be glazed, as that makes them slippery. In addition to being non-slippery they should have good resistance to abrasion and be dense enough to prevent the absorption of dirt and moisture. Vitrified, but unglazed, ceramic tile has these properties and because of this and its harmony with the glazed wall tile it is usually found in the high grade toilet and wash room construction which calls for glazed tile on the walls. It also makes a high grade flooring for cold storage rooms. The color is preferably white or cream. The high wearing value is shown in the table under "Composition."

Encaustic tiles are those which have the main body of one color of clay and patterns laid in other colors of clay before firing. Ceramic tiles are often called mosaic tiles, the latter word having reference to patterns made by the use of tiles of different colors.

Brick tiles have been previously dealt with.

There are various special makes of floor tile, some of which are designed to be particularly non-slippery and wear resistant.

Tiling is laid in Portland cement backing which should have expanded metal or similar reinforcing in it. The cement should be at least 1¼ inch thick and the tiling be laid and grouted just after the cement is laid and before it has reached its initial set.

The Most Interesting Job in the Yard

Another spokesman for the ship designers, or ship draftsmen, has something to say this month as to why their work is the most interesting in the yard. How about YOUR job? How does it compare with the others discussed under the above heading? Tell us about it.

ALL of us who work find, at least spasmodically, something absorbingly interesting in our task but to only a few of us is it given to discover a sustaining interest before we have reached that period in life when we are expecting time to knock at the door and say that our years of usefulness are at an end. At that moment, how many intelligent people are ready to lay down their work? How many of them do not feel that just then they are prepared to accomplish something really worth while? The years that have oozed away were spent in the daily struggle for the daily bread, or wasted in vain pursuits and endeavors, but, now, when old age has robbed them of their strength they eagerly desire to accomplish something more lasting, to do something creative. And never did work seem so alluringly tempting, so intensely interesting as do these creative tasks of the future that must be left to someone else to do or that must go undone.

That is the key to interest in work, the doing of something creative whether it be in the field, in the shop or in the office, and the lack of interest, with the consequent "labor unrest," is usually traceable to the inability of the worker to see the creative value of the task assigned to him. Of all the tasks that are necessary for the creation of any of the multitudes of products of modern industry, those which are most inclusive, which most completely survey the entire process of manufacture or creation, necessarily have the strongest and most lasting hold on the interest. And what task is more inclusive than that of the designer who follows the entire process from the first conception to the last polishing touch of completion? And what designer has a wider, a more inclusive range of interest than the designer of ships—even though he be only a "scrub draftsman" to whom it is given to see, in the plans he handles, the seed of a floating, moving, living ship? To be sure, some people succeed in taking an interest in fields of work where no finished results are ever visible, but I am inclined to believe that their interest is forced, that it is sustained by their determination to shut out from their consciousness every feeling of incompleteness, every suspicion of disappointment or of lagging of interest because the results of their efforts are not satisfying to themselves.

Admittedly, there may be a gambling interest in work—the interest of the financier who plays the game and takes his losses as well as his gains. No doubt there is also a touch of romance in such activities, as, for example, in the financing of the manufacture of a product that is sent over the seven seas to the four corners of the earth. But I sometimes wonder why the really successful financiers so often turn to philanthropy. The moralist may mutter something about the compunctions of conscience, but is it not possible that the building of libraries and colleges and hospitals is at bottom nothing but the fulfillment of a desire to do something more lasting than the hoarding of wealth, to accomplish or take part in something creative, to see something grow—other than the figures on the credit side of the ledger? If this postscript of creative work really is, though perhaps unconsciously, intended to satisfy an inborn desire for useful labor, then the whole of the previous career must be regarded as but a preparation for the creative work and purely financial success is then measurable only by the extent to which it makes creative work possible. But without this long period of preparation, it is possible for all of us to do useful, creative work, work that is necessary for the making of a finished product.

And when the finished product is a ship, with the relative lack of repetition usually met with in ship work, the appeal

is even greater than with most things that ordinarily come under the head of finished products—and all the more so when your share of the building is that of a draftsman. There was the first, rough, preliminary design, perhaps preceded by a study of service conditions. Follows then that fascinating game of give and take, the aim of which is to satisfy all concerned as far as possible, and which is ordinarily known as chosing the lesser of two evils. And that is a game continued until the ship is delivered and you heave a sigh of relief, for way back in the dawn of the history of this contract there was the estimate, which has been hanging over your head like the sword of Damocles, that document of figures covering a score or more of trades in steel work alone, covering steam and electrical engineering, piping and plumbing and wiring, carpentry and joiner work, rigging and equipment, painting and cementing. Although not, to be sure, master of all these trades, the draftsman, when he also officiates as estimator, makes prodigal use of detailed cost figures pertaining to them all, not to mention overhead costs, only to find it a rather painful performance to work within the estimate when the day of reckoning has come.

Not that his life is made up of estimating and days of reckoning only. There are many days of growth, growth of plans and material piles in the yard, growth of the ship's structure from the time the keel blocks are lined up and the keel is laid until the day when the vessel gracefully slides down the ways amid the blowing of whistles—yes, growth even until her rigging is set up and the first smoke is starting to curl up from her stack. Did you ever watch the floors and frames go up from day to day? Did you ever see the shell plating grow and gradually envelop that skeleton we call the framing of the ship, just as the spring foliage gradually envelops the twisted skeletons of trees and shrubs? If you have seen these things, and if you have had any part in the growth of a ship, you know the feeling and the interest that observing this development produces.

And the interest does not end even when the ship, the curl of smoke changed into a long, thin streamer, speeds away from the yard. So long as that ship floats and sails the seas your thoughts are more or less with it—sympathetic thoughts, which make you feel that this thing of steel and iron that you have helped develop from a mere conception is almost a living thing that carries with it something of your personality, for is not part of yourself woven into it?

And again, there is the larger view, the broader interest: each ship you help build becomes a unit of a fleet, be it merchant or naval, destined not merely to do its share of the world's work for the term of its life but also to be a foundation for the ships of the future, for better ships and safer ships, if not for larger ships, and to add its mite to the store of general knowledge and skill that makes the advancement of the world possible.

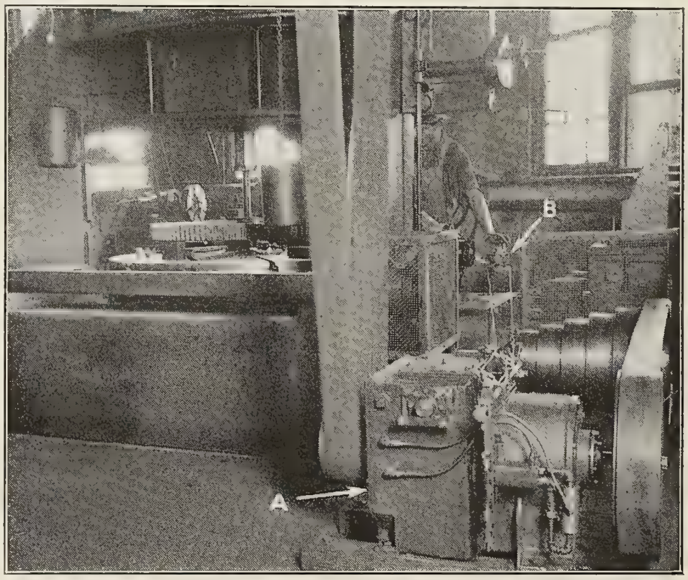
Quincy, Mass. John Flodin.

Oil Pressure Power Transmission Applied to Machine Tool Operation

In applying variable speed, oil pressure, power transmission devices to machine tools the Oilgear Company, Milwaukee, Wis., has developed a feed control and a variable speed drive to eliminate the manual work of controlling medium and heavy machine tools. The feed control system consists essentially of a pump which may be adjusted through a wide range of delivery capacity and a motor driven by the oil received from the pump. The pump is ordinarily driven from the countershaft of the machine tool on which the control is applied and the motor attached to the carriage or ram on which the feed is desired.

Two types of feeding motors are employed: the direct acting pushing cylinder and the rotary motor, the former being used when space conditions permit. For very long machines and frequently for cross feeds where it is necessary to have a screw control of the tool slide, the rotary type of motor is used. A feature of the feed gear, is the rapid traverse movement obtainable which enables the operator to move heavy carriages and rams without fatigue. The feed control permits the operator to increase the feed when cuts become lighter, back out the tool for examination of the cutting edge and return it quickly into the cut without disconnecting the friction clutches, etc.

Delivery of fluid from the feed controller, varied in quantity and direction, compels the feeding motor to perform exactly the function desired by the operator. The pressure in the system is large or small according to the resistance offered to the cutting tool, but the feed motor moves at the exact rate of speed called for by the operator without regard to the pressure required to do the work. If this pressure rises above the maximum necessary for feeding, a relief valve



Rear View of 7-Ft. Boring Mill Equipped with Oilgear Variable Speed Drive

opens and permits the feed motor to come to a standstill. This property is made use of in locating shoulders and the like in work to be machined as it is only necessary to set rigid stops and allow carriage to run against them as desired.

In addition to its use on lathes and the like, the variable delivery pump may be applied to presses and boring mills. An example of this is given in the accompanying illustration, where the device is shown applied to a 7-foot boring mill. This machine is driven by the standard feed controller requiring only a belt drive from a line shaft.

A larger type machine, designed to drive the spindles of machine tools from a line shaft, a constant speed electric motor or a gasoline engine has also been developed by the Oilgear Company. The principle of operation is similar to that of the feed control system, securing for the operator a wide range of speed changes in either direction through the manipulation of a single control handle.

Japanese Shipbuilding.—At the present time there are 14 Japanese shipbuilding establishments capable of constructing ocean-going merchant ships as compared with a total of 53 yards in 1918. Of these 14 plants only nine are actually engaged in new construction. The estimated output of the Japanese yards for 1921 was 40 vessels aggregating 190,000 gross tons. The maximum output occurred in 1919 when 136 vessels, totalling 621,513 gross tons were built.

The Still Engine

By L. B. Chapman*

This is a combination Diesel and steam engine, devised to increase the thermal efficiency over that of the Diesel engine. The heat ordinarily rejected in the jacket water and to the exhaust is used to produce steam and about 8 percent of this heat is converted into useful work, increasing the brake horsepower of the engine about 30 percent.

FROM the diagram of the Still engine shown in Fig. 1 it will be seen that in its present form the engine is double acting with the Diesel cycle working on top of the piston and the steam cycle below the piston. The water jacket is connected in a circuit with the boiler and an exhaust generator as shown in the diagram. The cooling water enters and leaves the jacket at a constant temperature corresponding to the pressure of the steam in the boiler. The heat absorbed by the jacket water surrounding the combustion cylinder is used to convert the water into steam

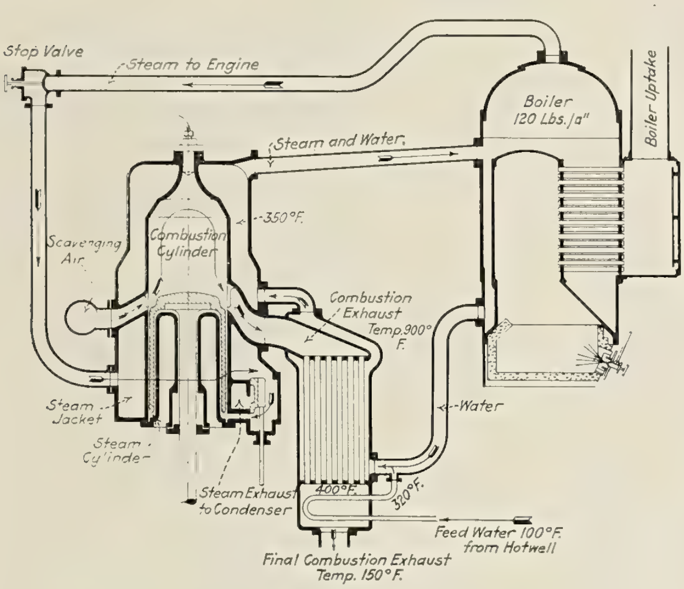


Fig. 1

at constant temperature. In other words, the heat of combustion that radiates through the walls is transferred into latent heat of steam. The steam thus generated passes to the boiler. The function of the boiler is to produce steam for warming up and starting the engine and to augment the supply generated in the jackets, if the jacket supply is not sufficient for the steam end of the cylinder.

The boiler feed water is circulated through the jacket as shown in Fig. 1. The feed water is taken from the feed tank by the feed pump as in all steam plants and is delivered at about 100 degrees to a feed heater or exhaust generator where it absorbs the heat in the exhaust gases. The temperature of the feed water is thus raised from 100 degrees F. to between 350 and 450 degrees F. and the exhaust gases are reduced from 900 to 150 degrees F. The feed water then enters the jacket where it is converted into steam by the heat of combustion.

The steam from the boiler enters the lower part of the cylinder and acts on the piston in practically the same manner as in a steam engine and is then exhausted to the condenser. Cylinder condensation, which is a large loss with the ordinary steam engine, is practically eliminated in the Still engine because of the heat received from the combustion of the gases in the Diesel end.

During compression of the air on the Diesel side of the piston the air charge absorbs heat from the cylinder walls because of the high temperature in the jacket. With the straight Diesel engine the transfer is in the opposite direction, due to the cold circulating water. One result of this is that the required compression pressure is less in the Still engine than in ordinary Diesel engines.

Advantages of Combined Cycles

The advantages due to the interaction of the combustion and steam cycles are summarized by Mr. F. E. D. Acland in a paper before the Royal Society of Arts as follows:

1. The mean temperature of the cylinder walls is higher than in ordinary engines; the cooler parts being maintained at a higher, the hotter parts at a lower, temperature.
2. The piston is cooler, owing to the expansion of the steam behind it.
3. The heat efficiency of the combustion cycle is augmented owing to the walls being at a higher and constant temperature, and is in proportion to the rise in temperature of the jacket water.
4. Frictional losses are reduced by the higher temperature, and by the steam overcoming the inertia of the reciprocating masses at the lower dead center.
5. The mechanical efficiency of the whole engine is higher than that obtainable in a normal engine of similar type.
6. The steam, expanding as it does in a cylinder hotter than itself, gives an indicator diagram larger than that theoretically obtainable under ideal conditions in an ordinary steam engine.
7. Twenty-nine percent of additional brake horsepower is added to the shaft of the engine without increase in the fuel consumption. (Steam not condensed.)
8. Forty percent is added when condenser is used. (Air pump separately driven.)
9. The indicated horsepower due to steam appears as brake horsepower added to the shaft, all the mechanical losses having already been accounted for in measuring the combustion brake horsepower.

Besides the merits listed above the two-cycle Still engine has the following advantages:

1. Fuel consumption 10 to 20 percent lower than the Diesel engine.
2. Absence of cold circulating water causing large temperature difference and trouble with cylinder and head castings.
3. Absence of cylinder condensation in steam end.
4. Lower compression pressure.
5. Absence of air starting, circulating and piston cooling system.
6. Absence of exhaust valves and gear.
7. Increased horsepower for a given bore and stroke.
8. Possibility of overload by forcing steam boiler.
9. Maneuvering at low revolution per minute is possible.
10. High temperature range 2000 to 150 degrees F. (Carnot efficiency).

Trials with a single cylinder two-cycle Still engine were carried out during 1921 by Scott's Shipbuilding & Engineering Company, Greenock, Scotland. Owing to the fact that the experimental engine had only one cylinder, it was necessary to provide a small auxiliary high pressure steam cylinder, the lower end of the main Still cylinder serving as a low pressure steam cylinder. In an actual installation where several cylinders are used the lower part of one can

*Professor of naval architecture and marine engineering, Lehigh University, Bethlehem, Pa.

be used as a high pressure cylinder and the lower part of another as a low pressure cylinder, thus obviating the use of an auxiliary cylinder. All the auxiliaries except the scavenging air pump were driven off the main engine in these trials.

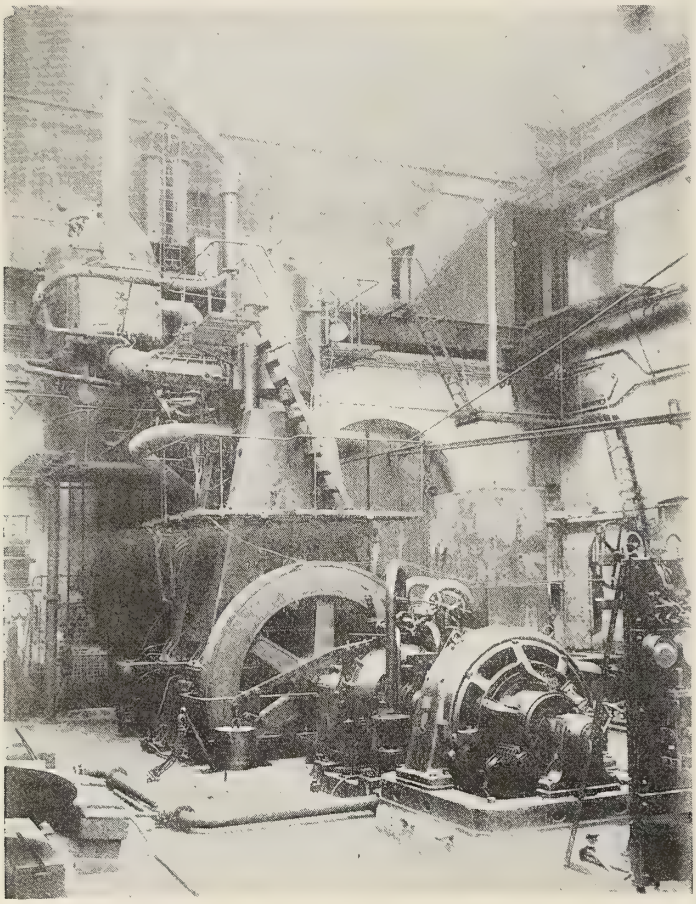

Fig. 2.—Still Engine Undergoing Shop Test

A photograph of this engine is shown in Fig. 2, and a diagrammatic view showing all the auxiliaries in Fig. 3.

The result of the trials of this engine are given in the following table:

Trials of 22-Inch by 36-Inch Still Oil Engine

Main Still cylinder—Stroke, 36 inches. Bore, 22 inches. Piston rod, 6¼ inches.

Auxiliary high pressure cylinder—Stroke, 14 inches. Bore, 22 inches.

	Over-load	Full Load	Half Load
1. Average combustion M. E. P., lbs. per sq. in.	88.9	81.2	54.2
2. Average steam M. E. P. referred to H. P. .	4.43	3.80	1.26
3. Average steam M. E. P. referred to L. P. .	7.36	6.23	3.60
4. Total M. E. P.	100.69	91.25	59.06
5. R. P. M.	128.1	124.3	103
6. Steam boiler pressure, lbs. per sq. in. gage.	112	100	108
7. H. P. receiver pressure, lbs. per sq. in. gage.	75	57	23.5
8. L. P. receiver pressure, lbs. per sq. in. gage	11	5.5	0.4
9. Vacuum, inches Hg	28	27.5	26.6
10. Water evaporated per hour, lbs.	950	807	388
11. Scanvenging pressure, inches water	49	46	40
12. H. P. for scavenging	15.4	14.1	12.0
13. Combustion I. H. P.	394	349.5	192.5
14. Total I. H. P.	446	392	210
15. Engine B. H. P.	384	343	174.5
16. Net B. H. P. (line 15—line 12)	368.6	329	162.5
17. Oil per hour, lbs.	146.6	123.4	64.0
18. Oil per net B. H. P. per hour	.398	.375	.394
19. Efficiency on net B. H. P., percent	35.5	37.7	35.8

It will be observed that the fuel consumption at full load is 0.375 pound per brake horsepower, which is about 10 percent lower than the best four cycle Diesel practice and nearly 20 percent better than the general run of two cycle Diesel engines.

Claims are put forward that the Still engine weighs less and occupies less space than the Diesel engine. The gain in economy of between 10 and 15 percent for this single cylinder engine is highly encouraging and no doubt this can be improved upon when several cylinders are used. At first thought the engine appears complicated but it must be borne in mind that the air starting, circulating and piston cooling systems are eliminated and the small boiler employed with

the Still engine would generally be required on a Diesel ship for heating purposes.

It would seem that the claims of the inventor are borne out by the recent trials and the engine has excellent possibilities for marine propulsion. The diagrams, photograph and data in the above article were kindly supplied by the Still Engine Company, of London.

Munson Elected Member of Executive Committee of Merchant Marine Association.—Frank C. Munson, president of the Munson Steamship Lines, has been elected a member of the executive committee of the National Merchant Marine Association, according to an announcement by Senator Joseph E. Ransdell of Louisiana, president of the association. "Mr. Munson's election to the executive committee," says Senator Ransdell, "is very important, as he brings to it long practical experience in steamship management, both as owner and as operator of United States Shipping Board vessels."

Questions and Answers for Marine Engineers

Inquiries of General Interest Regarding Marine Engineering and Shipbuilding Will Be Answered in This Department

Conducted by James L. Bates

This department is maintained for the service of practical marine engineers, draftsmen and shipbuilders. All inquiries should bear the name and address of the writer. Anonymous communications will not be considered. The identity of the writer, however, will not be disclosed unless the editor is given permission to do so.

Weight of Speaking Tubes on Warships

Q. (1156).—Can you give me an idea of the weight devoted to speaking tubes on a war vessel?

A. (1156).—During recent years the necessity of prompt communication between various parts of a vessel has been emphasized. The effect in terms of weight in the case of war vessels is apparent from the figures given below for brass voice tubing and fittings:

	Tubing	*Fittings*
Battleship	56,000 pounds	19,000 pounds
Scout	10,500 pounds	3,500 pounds
Destroyer	7,250 pounds	1,950 pounds

Point of Maximum Valve Lead

Q. (1147).—If a marine engine has a given lead (on the top and bottom dead center), is that the greatest lead or full port opening that the valve will have? In other words that lead will not increase as the crank leaves the dead center top or bottom?

A. (1147).—In practice the port opening does increase as the crank leaves dead center. In order that full port opening might exist at dead center or the beginning of the stroke the radius of the eccentric would have to be in line with the crank radius; that is, the eccentric would be on the opposite dead center to that of the crank. Such an arrangement would mean that cut-off would begin with the commencement of the stroke and that all the other operations of the cycle, expansion, exhaust, etc., would take place in their order at a correspondingly earlier point in the stroke than in good practice.

Mean Effective Pressure

Q. (1148).—Don't you think 110.875 pounds is pretty high for a mean effective pressure in the following example? What do you think of the formula?

A marine engine has an absolute pressure of 125 pounds per square inch, with a cut-off of ⅝ of the stroke. The pressure in the condenser is 14 pounds or 28 inches of vacuum. What is the mean effective pressure?

Constant for a ⅝ cut-off from slide rule is .919, then $125 \times .919 = 114.875 - 14$ or 100.875 mean effective pressure.

A. (1148).—With a vacuum of 28 inches (corresponding to 14 pounds pressure) in the condenser a pressure of, say 3 pounds (known as back pressure) might be expected at the engine exhaust which we will call p. With ⅝ cut-off the number of expansions would be $1 \div .625 = 1.6 = r$.

P_1 = pressure in steam chest = 125 pounds absolute

$$P_m = \text{theoretical M.E.P.} = P_1 \times \frac{1 + \text{hyp. log } r}{r} - p$$

$$= \left(125 \times \frac{1 + .47}{1.6}\right) - 3 = (125 \times .919) - 3 = 111.9 \text{ pounds}$$

The value of P_m is a figure which might be expected from a perfect engine having dry steam expanding at a constant temperature. In the actual engine as built there will be losses in pressure due to friction of steam during admission and cut-off, also through ports and passages, condensation of steam due to the cooling action of the cylinder walls and passages, opening of valve to exhaust before piston reaches end of stroke, also compression and back pressure due to lead. All these losses may be taken care of by a factor, the value of which depending upon the type of engine and valve gear, number of cylinders, piston speed, whether condensing or non-condensing, jacketed or non-jacketed. When possible this factor value should be derived from a similarly constructed engine.

For the single cylinder engine under discussion this factor, which we will call F, may be taken as .70. Then the actual mean effective pressure would be

$$P_m \times F = 111.9 \times .70 = 80.4 \text{ pounds}$$

Bottom Blow Valves

Q. (1152).—Please give a brief explanation of the bottom blow valve of ocean going steamships, and a description of each kind.

A. (1152).—The object of the bottom blow valve is to blow out of the boiler into the sea, with the boiler's own steam, mud and sediment which may collect at the lowest part of the boiler, or for emptying the boiler for the purpose of cleaning or examination. In the case of express type boilers where two or more lower drums are fitted, each drum would require its own bottom blow valve.

The valve may be attached directly to the boiler or as is often the case an intermediate blow-off cock or valve may be fitted. The one nearest the boiler being opened wide and an outer valve used to control the blowing-off operation. The valve's location should be at the lowest point; but, if this is found to be impracticable, it may be placed at some higher point with a connecting internal pipe running to the bottom point. This valve in turn is piped to a valve at the ship's shell.

There are so many blow-off valves on the market, that it would be impossible to enumerate their detail differences. They may, however, be divided into four principal types and designated as "seat," "seatless," "gate" and "cock."

The first type is much on the order of an ordinary globe or angle valve in appearance, the seat being easily removable and so designed together with its disk as to eliminate so far as possible the lodging of scale in such a way as to prevent the valve being closed. The valve is so attached that steam is always on top of the disk.

The second type consists essentially of a hollow piston, either with a series of ports around its circumference or an internal elbow passage, and is so constructed that there will be no projection upon which scale or sediment can collect. The pressure is against side of piston when valve is closed.

The third type is essentially a specially designed gate valve which permits of a straight through flow when the disk is drawn up to its open position.

The fourth type is simply a plug cock having a spring or other device on the top side of the plug for holding it securely in place and to take up wear, thus preventing the accumulation of scale and sediment.

LETTERS TO THE EDITOR

Oil Burners Overtax Feed Water Heaters

I have read with much interest your article in the February number of Marine Engineering and Shipping Age concerning the trial of the S.S. *Independence,* fitted with Peabody-Fisher wide range, one-man control oil burners. This article was much to the point. I note, however, that it states that the low temperature of the feed water was due to the arrangement of the measuring tanks installed on the boat deck.

This arrangement consisted of pumping the water from the hot well up to the measuring tanks, from which it was discharged into a temporary tank on deck, to which the suction of the feed pump was connected. It will be obvious, therefore, that very little loss in temperature in the feed water took place, as the only source of cooling would be a slight amount of radiation during the passage of the water from the measuring tanks to this temporary "hot well."

On the other hand, please note that we were making steam at a rate very much beyond the ordinary requirements and the excess steam was escaping through the safety valves. In fact, during the latter part of the test, more than 62,000 pounds of steam were being generated per hour, whereas the maximum requirements of the vessel were estimated at 45,000 pounds.

Thus the quantity of feed water passing through the heater was far in excess of the normal amount, while the exhaust steam from the auxiliaries entering the heater remained unchanged; the natural consequence being that there was not enough exhaust steam to heat the abnormal amount of feed water above 168 degrees.

This, of course, is no reflection on the design or operation of the machinery but merely an example of the very high capacity at which the boilers were being forced. If the boilers had not been forced, the feed temperature would possibly have been 210 degrees Fahrenheit or more.

I subscribe fully to your comment concerning the effectiveness of the soot blowers. Had they been used earlier in the test, doubtless a still higher efficiency would have been obtained from the boilers. However, I am sorry that you did not add a statement to the effect that very little or no smoke was produced during the trial, as it might appear to the average reader that the boilers were badly sooted up during the trial. This, of course, was not the case.

At about the end of the trial, while the vessel was entering the harbor at full speed, the engineer got a bell to stop and the main engine was immediately shut down. The operation of our wide range control came into service at this time and merely by the turn of one valve on the bypass line all fires were reduced in capacity so that the safety valves were prevented from blowing. At the end of a period of about five minutes the signal "full speed ahead" was given and again, by the turn of the valve, the fires were accelerated and the steam pressure maintained, with the engines developing full capacity.

In other words, it was not necessary to touch any of the burners; none of them was extinguished; cold air was prevented from entering the furnaces (thus preventing contraction strains) and, when starting up again, it was not necessary to get out the torch and light up any burners.

It has been claimed that our flexible system is of no use on merchant vessels, where the load on the boilers is uniform and steady. However, the above incident shows that there are many occasions when the bypass comes into excellent service. No change of tips is necessary when getting up steam on cold boilers. All maneuvering is easily handled by the bypass, and it frequently happens at sea that on account of fog or heavy weather the engines have to be slowed down.

The tanker *Illinois* of the Texas Company has now been in service some eight months, and it has been found that the flexibility of the system is of great advantage.

New York.

Peabody Engineering Corporation,
E. H. Peabody, President.

Marine Boilers

In your issue of September, 1921, there appears an article entitled "The Selection of Propelling Machinery," by Professor Lawrence B. Chapman, in which he, like many other persons, makes comments upon marine boilers which, I believe, are not justified.

He begins the part on boilers by stating that the lighter express types of watertube boiler are unsuitable for merchant service, and ignores the fact that the *Berengaria* (ex-*Imperator*), *Leviathan, Great Northern, Northern Pacific* and most of the "State" ships of the Shipping Board have such boilers and apparently are satisfactory. The forthcoming *Majestic* of the White Star Line also has them and I imagine that many ships in the future will be so provided. The *Berengaria, Leviathan, Majestic* and "State" ships have boilers of the Yarrow type and the *Great Northern* and *Northern Pacific* have Mosher boilers. I have not heard of any trouble from them and it is well known that the two latter steamers, when used for transports, made the quickest round trips between New York and Brest of any steamers.

Concerning Professor Chapman's comments on Scotch boilers, I disagree with him and assert that the Scotch boiler has good circulation after it has once been heated up; that it can be easily forced and that its efficiency is superior to that of any marine watertube boiler. With it it is important to raise steam slowly and to circulate the water artificially while this is being done. When the results of the tests of the 15-foot 3-inch Scotch boiler at the Sun Shipbuilding Company's plant at Chester, Pa., carried out by the Emergency Fleet Corporation in 1920-21 are published, many persons will be enlightened on these matters. They will find that the combustion was excellent, that the economy was unusually high, that the circulation was perfect, as shown by thermometers inserted through the shell at top and bottom, and that there were no drawbacks.

Concerning forcing, what can possibly prevent burning a large quantity of coal in a Scotch boiler, if the draft is sufficient—that is what forcing consists of. The draft, being usually artificial, can be sufficient to force any boiler. Can the Sotch boiler respond with economy when forced? It surely can, and the Emergency Fleet tests prove it, especially when retarders are used. People are misled by the temperatures of the escaping gases from Scotch boilers. They are higher than from watertube boilers because there is no air leakage to cool them as in the case of watertube boilers. This is a valuable feature as the hotter gases are effective in superheating the steam and heating the air with the Howden system.

Is there any reason for anticipating more injury to a Scotch boiler from forcing than from ordinary use? I can see none as the distribution of temperatures is as equable when forcing as when not, and it is the absence of this that causes injury to boilers. Furthermore, unusual forcing of boilers at sea seldom occurs.

By an examination of an article in *The Engineer* of September 23, 1921, on the tests of the Inglis Scotch boiler it will be seen that this boiler surpasses in economy all other boilers in existence, whether on land or sea, even when burning 49 pounds of coal per square foot of grate per hour

with an air pressure of 3 inches, and apparently without heated air for combustion. The tests of these boilers were made by five different firms or individuals in good standing, and the results were as follows:

Tests by	Coal burnt per square foot grate per hour, pounds	Heat value of coal, B. T. U.	Temperature of escaping gases, degrees F.	Evaporation per pound of coal from and at 212 degrees F., pounds	Efficiency, percent
Burstall & Monkhouse	19.82	14,350	439	12.97	87.34
	27.31	14,280	482	12.24	82.80
	48.89	13,890	523	11.33	78.80
Prof. Stanfield	20.10	14,080	457	12.70	87.58
	33.20	14,080	475	11.82	81.32
	48.00	13,600	524	10.94	77.82
John Brown & Company, Ltd.	38.70	13,647	498	12.08	85.00
	48.90	13,647	593	11.40	80.20
Denny & Company	16.20	13,864	470	12.87	89.50
	19.00	13,864	410	12.70	88.40
	29.00	13,864	440	12.08	84.10
The Fairfield Shipbuilding & Engineering Company, Ltd.	19.20	13,952	445	12.45	86.21

These results easily surpass any that have ever been obtained from any other type of boiler, when hand fired, and constitute an epoch in boiler performance. The Inglis Boiler Syndicate guarantees 80 percent efficiency, which has never been done before.

The Scotch boiler lends itself to superheating readily, and, by the use of the locomotive type of superheater, to high degrees. Its defects are its cost, weight and space occupied. It is not as sensitive to salt as the watertube boiler, salt being the great enemy of the latter.

Boston, Mass. F. W. Dean

NEW BOOKS

Electric Ship Propulsion. By Commander S. M. Robinson, U. S. N. Size, 6 by 9 inches. Pages, 274. Illustrations, 140. New York, 1922: Simmons-Boardman Publishing Company.

Electricity as a prime mover for ships has been proposed for many years and a number of excellent papers on this subject have been presented from time to time before technical societies both here and abroad. It has remained, however, for Commander Robinson to present the first book devoted in its entirety to electric propulsion.

The United States Navy was the first to recognize the possibility of electric drive for ships and the author's experience with the design and operation of naval craft so propelled is such as to place him among the foremost authorities on this subject in the world. As might be expected, a goodly portion of the book is devoted to electric drive installations in naval vessels, but the application of this method of propulsion to merchant craft is taken up in no less detail.

Chapter I deals with the history of electric propulsion and the types of ships for which it is best adapted. Comparison of electric with turbine and Diesel installations is made clearly and concisely and deductions arrived at which indicate the type of machinery best adapted for various classes and types of vessels.

Chapter II describes the electrical systems most suitable for marine propulsion and discusses the reasons for different systems in various types of craft.

In Chapter III the characteristics of propellers are dealt with from the viewpoint of the effect of the propeller on the design of the ship's motor. The design of motors and generators to meet the conditions imposed by the propellers is fully treated in Chapter IV, while Chapter V describes the characteristics of turbines and governors for electric propulsion.

Ventilation and heaters as a means of protecting the motors and generators are described in Chapter VI as are also proper fire extinguishing apparatus for preventing damage from fire caused by a short circuit. Switchboards, interlocks and control apparatus are dealt with in Chapter VII, and the proper type and kind of wire, cable, insulators and insulation is given in Chapter VIII.

Chapter IX takes up the installation of exciters and other auxiliaries which are required for furnishing excitation to the main generator field. The next five chapters are devoted to describing in detail the electric drive installations installed in some of the naval vessels including the initial experimental installation in the collier *Jupiter* and the latest improvements as installed in the latest battleships.

A typical installation in a ten-knot cargo vessel of 6,000 tons capacity is described in Chapter XV where the Ljungstrom system of electric propulsion, as applied to the *Wulsty Castle*, is set forth in detail. Chapter XVI is devoted to the description of Diesel electric drive and deals with the future possibilities of this type of prime mover for merchant vessels, while the concluding chapter describes the care and upkeep of electric propulsive units and gives a number of practical hints which will aid in keeping the machinery in proper working order.

Commander Robinson's book has been skilfully prepared and its value is greatly increased by the many illustrations showing actual details of existing installations. The increasing trend of modern practice in the direction of the application of electricity as a prime mover for ships has created a demand for an authoritative text-book on this subject which is fully met by this book. It should have a place in the libraries of all students of modern marine engineering.

PERSONAL MENTION

George H. Wells, of the traffic department of the Shipping Board, is to be appointed to the executive staff of the United States Lines.

Francis M. Wolf, who has been assistant passenger traffic manager of the Munson Steamship Line, has been made passenger traffic manager.

J. T. Borden, formerly of Chester, Pa., has been placed in charge of the recently opened New York office of the Sun Shipbuilding Company at 25 Broadway.

Gale H. Carter, a director of the Pacific Mail Steamship Company since last September, has been elected president of the company to succeed George J. Baldwin.

George J. Baldwin, president of the Pacific Mail Steamship Company, has been elected to the newly created office of chairman of the board. Mr. Baldwin's resignation as president will relieve him of the active management of the company, which he has had for the past six years.

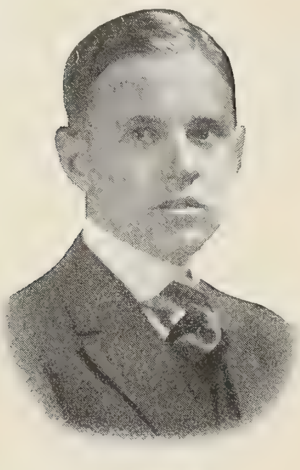
R. H. M. Robinson, chairman of the executive committee and, during the past year, acting president of the United American Lines, has been elected president of the company. At the same time A. D. Tomlinson was elected vice-president. Mr. Tomlinson is vice-president of the American-Hawaiian Steamship Company, for which the United American Lines are managing agents.

George G. McIntosh, formerly passenger traffic manager of the Munson Steamship Line, will assume the duties of European service manager for this company.

R. I. Dunigan has been named as successor to Edward Wortmann as assistant general passenger agent of the United States Lines. Mr. Dunigan was formerly traffic director for the Baltic Steamship Company.

M. J. Buckley, assistant to A. J. Frey, vice-president of the Shipping Board, has resigned and intends to return to San Francisco, where he was formerly connected with the Pacific Mail Steamship Company.

Charles F. Gross of Baltimore, Md., has been made assistant professor of marine engineering and naval architecture at the College of Mechanics of the University of California, Berkeley, Cal. Professor Gross graduated from the department of naval architecture and marine engineering of the Massachusetts Institute of Technology, after which he became instructor at the United States Naval Academy, Annapolis, Md., in the department of marine engineering and naval construction. For some time after the war he was associated with the Union Shipbuilding Company, Baltimore, Md. Professor Gross is a member of the Society of Naval Architects and Marine Engineers and of the American Society of Naval Engineers. The course in naval architecture with which he is connected at the University of California was started in January, 1918, under the instruction of Professor D. W. Dickie, a well known naval architect on the Pacific coast.



Charles F. Gross

Eric Krag has been appointed manager of the newly formed chartering department of the General Steamship Corporation, San Francisco, Cal. He was formerly connected with the East Asiatic Company in Copenhagen and came to this country in 1914 as assistant general Pacific Coast manager of the company.

J. P. Sutherland has been appointed eastern passenger agent for the Pacific Mail Steamship Company with headquarters at 10 Hanover Square, New York City, to handle the newly established San Francisco-New York service of the company. Mr. Sutherland was formerly manager of the passenger and mail section of the United States Shipping Board.

J. L. Ackerson, president of the Atlantic Coast Shipbuilders' Association, has been named a member of the committee recently formed by the Chamber of Commerce of the United States to consider policies to be adopted in connection with the American merchant marine. The committee is made up of men prominently identified with business and shipping interests.

James W. Boring has been appointed manager of the advertising department of the United States Shipping Board Emergency Fleet Corporation to succeed M. B. Claussen who was forced to resign this position on account of ill health. Mr. Claussen, however, will remain in the employ of the Shipping Board, supervising the development work of the various transpacific passenger services on the Pacific coast and in the Orient.

P. J. Pearce was recently elected president of the Puget Sound Maritime Circle. Mr. Pearce has been acting president of the organization for some time. The Maritime Circle comprises staff employees of steamship and transportation companies in Seattle.

Joseph Scott, assistant general manager of the States Marine and Commercial Company, New York, has resigned this position to become manager of the steamship department of the Transmarine Corporation, a subsidiary operating company of the Submarine Boat Corporation.

E. E. MacNary has been named by General Manager Rossbottom of the United States Lines to succeed J. M. Kennedy as general passenger agent of the company. Mr. Kennedy was recently transferred to London to act as European passenger agent for the lines with headquarters in London.

George W. Sterling, former assistant director of operations of the United States Shipping Board at New York, was recently elected president of the Foreign Transport and Mercantile Corporation. Mr. Sterling while with the Shipping Board acted as receiver for a number of companies which had bought Shipping Board tonnage and defaulted on their commitments for the vessels.

Captain Eugene O'Donnell, manager of the marine department of C. H. Sprague and Sons, Boston, Mass., has resigned as chairman of the committee on sea-going personnel of the American Steamship Owners' Association. President Raymond of the association has appointed A. J. McCarthy, vice chairman of the committee and manager of the American flag steamers of the International Mercantile Marine Company, to this post.

Robert Taylor Merrill has become director of the Bureau of Research of the United States Shipping Board. Mr. Merrill, prior to coming with the Shipping Board, was connected with the Oriental Navigation Company, in the capacity of operating vice-president. He is a graduate of the United States Naval Academy and during the war was supervisor of the United States naval auxiliary reserve, charged with the supervision of the officers and men of the merchant marine enrolled in the Navy. He was also district supervisor of the Naval Overseas Transportation Service, in charge of the physical handling of supply ships running to Europe. On his resignation from the Navy in 1919 he held the rank of lieutenant commander. The Bureau of Research will conduct investigations into maritime matters, making studies of world shipping and shipbuilding conditions in relation to their effect on American shipping.

© *Kadel & Herbert*
Robert T. Merrill

Nathan A. Smyth has been named as general counsel of the Emergency Fleet Corporation. The object of Mr. Smyth's promotion to the position of general counsel is to bring about a segregation of the legal work of the Shipping Board from that of the Fleet Corporation. Before becoming assistant to Elmer Schlesinger, general counsel of the Shipping Board, last July, he was associated with the law firm of Rushmore, Bishbee & Stern of New York. He was born in Quincy, Ill., in 1876, graduated from Yale in 1897 and the Yale Law School in 1900.

Shipbuilding, Reconditioning and Operation

Port Expansion, Passenger and Freight Activities and Other Notes of Interest in All Branches of the Marine Industry

Principal Details of Three Turbo Electric Ferryboats For New York City, To Cost Approximately $1,330,000

Vessels Will Be 218 Feet in Length Each, for Service to Staten Island—City Establishes New Record

PLANS and specifications for the construction of three electric drive steel screw ferry boats for the City of New York, having an estimated cost of $1,330,000, have been submitted by Grover A. Whalen, Commissioner of Plant and Structures, to the Board of Estimate and Apportionment for approval, according to official information obtained by MARINE ENGINEERING AND SHIPPING AGE. The boats will have a length over all of 218 feet, length between end posts, 215 feet; beam over guards, 64 feet; beam molded, 45 feet; depth of hull at side molded, 18 feet.

Alternative bids are to be submitted for certain parts of the work and a lump sum bid per boat must be submitted for building two boats and three boats complete. The first boat must be entirely completed within 245 consecutive calendar days from date of certification of the work; the second boat within 275 consecutive calendar days from date of certification and the third boat within 305 consecutive calendar days from date of certification. The amount of security to guarantee the faithful performance of the contract will be $400,000.

The vessels are to be double ended ferry boats for carrying passengers and vehicles between St. George, S. I., and Manhattan, and are to have four driveways on the main deck without cabins, and a cabin and outside seats on the upper deck. The hulls and main decks are to be built of steel with steel main house sides and steel center house; upper decks together with houses and decks above to be built of wood. The Isherwood system of longitudinal framing will be used in the hull construction.

Alternative propositions will be received for steering gears, one providing for the installation of a steering gear on each end of the boat of the electric drum type together with a hand steering gear, each set being complete and independent of the other, and the second providing that a steering gear be installed on each end of the boat of the parallel cylinder electro-hydraulic type.

MACHINERY

For each vessel there will be one main turbine of the impulse type, direct connected to the main generator. This turbine shall be capable of delivering a maximum of 2,200 horsepower at the propeller shafts. The turbine speed shall be not less than 3,000 revolutions per minute when delivering 2,200 shaft horsepower. Under normal operating conditions the total shaft horsepower will be 1,900.

There will be one main generator designed for 2,300-3,000 volts and a maximum operating speed of not less than 3,000 revolutions per minute. Excitation required at full load when delivering 2,200 horsepower at the propeller shafts is not to exceed 20 kilowatts.

Two main propulsion motors are to be provided and installed of the three-phase, alternating current, induction type, 2,300-3,000 volts. Each motor is to be provided with a stator winding for operating the stern propeller at full speed and power (2,100 horsepower and about 176 revolutions per minute) and a stator winding for operating the bow propeller at reduced speed and low power (about 100 horsepower and 132 revolutions per minute).

AUXILIARIES

There will be two direct current turbo-generator auxiliary sets of 125 kilowatt capacity each.

All auxiliary motors are to be of the marine, direct current, compound or shunt wound, commutating pole, continuous rated, self-ventilated, splash-proof type, operating at 220 volts.

There will be one surface condenser installed in the engine room of the horizontal centrifugal, two-pass type, containing not less than 4,000 square feet of cooling surface.

The circulating pump is to be of the centrifugal, double suction, high speed type with a capacity of not less than 5,000 gallons per minute against a total head of 20 feet.

The condensate pump is to be of the centrifugal, balanced side suction, high speed type, direct connected to a motor. Two duplicate air ejectors are to be installed on the condenser, each one having a capacity sufficient to meet maximum conditions.

The steam pump equipment will include two vertical simplex feed pumps, one horizontal duplex fire and general service pump, two vertical simplex bilge pumps. One centrifugal double suction high speed salt water service pump, motor driven and one rotary type fresh water pump, motor driven, are also to be provided.

BOILERS

Four watertube boilers are to be installed The boilers are to have a working pressure of 250 pounds per square inch and to be constructed to allow for the installation of superheaters.

A superheater is to be installed in each boiler having sufficient surface to maintain 200 degrees of superheat to 30,000 pounds of steam per hour with four boilers in use under natural draft or with three boilers in use under forced draft.

Million Dollar Conversion Job, Involving Eleven Ships, Is Planned

Approximately a million dollars' worth of ship conversion work is receiving the serious consideration of the Admiral Line, of which H. F. Alexander is president, according to information obtained by MARINE ENGINEERING AND SHIPPING AGE. Mr. Alexander, who is at present in the East, is making his headquarters at the office of the Dollar Line, 11 Moore street, New York City. It is understood that the project now under contemplation involves the conversion of 11 vessels, 7 of which are steamers and 4 steel barges, into Diesel driven ships for freight service.

Five of the steamships, which are similar to the steamer *Cottonplant* type built by the Great Lakes Engineering Works for the Shipping Board during the war, are at present tied up at Norfolk, Va., and the other two steamships, the *Wallingford*, built by the Long Beach Shipbuilding Company, and the *Silverado*, built by the Craig Shipbuilding Company, are laid up on the Pacific Coast. The steamers are all about 4,000 deadweight tons each.

The barges, it is reported, are the *Dawnlite, Daylite, Starlite* and *Moonlite*, of about 3,000 deadweight tons each, and are tied up at Baltimore, Md.

It is believed that the conversion of the steamships, which are now equipped with triple expansion reciprocating engines, into motorships will cost $100,000 each with a probable cost of about $75,000 each for the installation of similar motive power in the barges.

Sun Shipbuilding Company to Build Doxford Opposed Piston Two-Cycle Oil Engines

Arrangements have been completed with the Sun Shipbuilding Company of Chester, Pa., for uniting the interests of the American Junkers Patents with Doxford Patents which have been the basis of the developments forming the Doxford opposed piston two-cycle oil engine.

The Sun Shipbuilding Company have already secured the full license in America and its possessions of the Junkers Patents and it will operate both interests in America. An immediate start is to be made at the Chester Works on the construction of a four-cylinder 3,000 horsepower single screw installation, being a duplicate of the Doxford manufacture, two of which engines are already at sea in the motor ships *Yngaren* and *Dominion Miller*.

This type of engine opens up with the brightest expectations to question of installing single screw Diesel engines for all types of vessels up to a very large tonnage.

Sun Shipbuilding Company Announced As Successful Bidder For New West Coast Express Passenger Ship Costing $1,027,000

ANNOUNCEMENT is made of the awarding of the contract for the construction of an express passenger steamer for the Inter-Island Steam Navigation Company of Honolulu, T. H., to the Sun Shipbuilding Company, Chester, Pa., at a price of $1,027,000 and 285 days, this company submitting the lowest bid. The vessel will be 360 feet in length and will have a speed of 16½ knots. She will be used in service around the Hawaiian Islands.

Thirteen bids were submitted by various Atlantic and Pacific Coast yards as follows:

		Days
Sun Shipbuilding Co.	$1,027,000	285
Newport News Shipbuilding & Dry Dock Co.	1,100,000	285
Bethlehem Shipbuilding Corporation	1,115,000	305
Federal Shipbuilding Co.	1,128,370	300
Los Angeles Shipbuilding & Dry Dock Co.	1,150,000	300
Merchants Shipbuilding Corporation	1,151,489	364
Bethlehem Shipbuilding Corp., San Francisco, Cal., plant	1,199,350	305
New York Shipbuilding Corporation	1,273,500	425
Staten Island Shipbuilding Company	1,275,000	365
Wm. Cramp & Sons Ship & Engine Building Co.	1,340,000	365
Todd Dry Dock & Construction Co.	1,350,000	245
Bath Iron Works	1,360,000	456
Union Construction Co.	1,468,300	300

Steel Hull for Dredge

The United States Engineer Office, Nashville, Tenn., will receive sealed proposals until 11 A.M., April 11, 1922, for the construction and delivery of a steel hull for a dredge. Further information on application.

Bids Asked for Steel Pontoons And Equipment for Dredge At Philadelphia

The United States Engineer Office, Philadelphia, Pa., will receive sealed proposals until 12 o'clock noon, April 6, for furnishing all labor and materials for and constructing 20 steel pontoons, 60 cast steel pontoon saddles and 30 cast steel pipe saddles with "U" bolts and washers, and 168 lengths of 18 feet each of shore discharge pipe complete. This equipment is for the United States dredge *Cataract*. It is estimated that the work will involve the expenditure of close to $20,000. Plans and specifications may be obtained upon application to the Engineer Office.

Contract for Steel, Diesel Driven Houseboat Awarded Consolidated Shipbuilding Corp.

A contract has been placed with the Consolidated Shipbuilding Corporation, Morris Heights, N. Y., for the construction of a new type of houseboat for John Ringling, plans and specifications for which were prepared by Henry J. Gielow, naval architect. The vessel will be of light draft, and combine the seagoing qualities of a good motor or steam yacht with the more material comforts of a houseboat.

The new craft will have an over all length of 125 feet 7 inches; length on load water line 117 feet 9 inches; beam 21 feet 3 inches; and 4 feet 3 inches draft when fully loaded. The propelling machinery will consist of two 6-cylinder Diesel engines of 180 horsepower each.

The boat will be constructed of steel, the shell plating being carried up to the upper deck.

Two Million-Dollar Passenger Ships To Be Built For Eastern Steamship Company For Boston-New York Line

Vessels Will Be of Highest Class, Equipped With Geared Turbine Engines, Burning Oil Fuel and Will Have Accommodations for Over 700 Passengers

BIDS are expected to be received within the next two months for the construction of two new passenger ships for the Eastern Steamship Company, Boston, Mass., at a cost of approximately $1,000,000 each, according to information obtained by Marine Engineering and Shipping Age. It is understood that the vessels are to be ready for operation by June, 1923. Plans and specifications are being prepared by Theodore E. Ferris, naval architect and marine engineer of 30 Church Street, New York.

Approximate figures give the size of the ships as about 400 feet in length over all, 56 feet beam and 17 feet load draft. The vessels will run on the Metropolitan Line between New York and Boston and will probably be more on the ocean type than the Sound type steamers. They will be single-screw ships driven by double reduction geared turbines.

It is understood that each vessel will be equipped with five single-ended Scotch boilers having 16,500 square feet of heating surface, 150 degrees of superheat, steam at 200 pounds pressure, delivering about 5,500 shaft horsepower and 98 revolutions per minute. The boilers will be fired by oil burners.

It is planned to have these ships surpass any other vessels in similar service. They are to be of the coastwise hurricane deck type equipped with complete double bottoms, lower, main, hurricane, promenade and boat decks with ports large enough for the handling of automobiles. They will be equipped to carry about 640 first class passengers in regular room, parlor and suite, and 100 berth travel or steerage passengers.

Norfolk, Va., Takes First Definite Steps Towards $5,000,000 Port Development

The Atlantic, Gulf & Pacific Company, with offices at Norfolk, Va., is low bidder, at a price of 17.89 cents per cubic yard, for the dredging of 750,000 cubic yards in the channel approaching the new Norfolk municipal terminals, which will be the first step in the construction of these facilities provided for in the recent $5,000,000 bond issue election. The bids have been referred to City Manager Ashburner for analysis and recommendations.

The company agreed to start the work in ten days after contract is awarded, and guaranteed to dredge 125,000 cubic yards per month until the work is finished. On two separate items of work in connection with this project and which embody certain small dredging and filling operations this company bid 30 cents and 50 cents per cubic yard, respectively. Their whole bid will bring the entire operation to $140,000.

Work on the terminals will begin with the least possible delay, the Port Commission has announced, and it is expected that before spring is far advanced the terminals will be under construction.

One of the big factors which entered into the bid of the Atlantic, Gulf & Pacific Company for the first dredging work, necessary to be done before the construction of the terminals can begin was the fact that this work could begin on ten days' notice. The element of time is the essence of the situation with regard to the grain elevator, in the opinion of the commission, because it must be ready for the next fall crop of grain or lose an entire year of operation.

As soon as the elevator plans are under way, plans for the piers and warehouses will be taken up. The commission feels that while all the development is urgent, its energies must be concentrated on construction of the elevator, to be followed by active steps to complete the entire project.

47,000 Gross Tons of New Shipping Admitted to American Registry During Month of February

The Bureau of Navigation, Department of Commerce, Washington, D. C., reports 39 sailing, steam, gas and unrigged vessels of 38,359 gross tons built in the United States and officially numbered during the month of February, 1922.

No vessels are reported as having been built in this country for foreign owners during the month.

Forty-three vessels having a total of 24,909 gross tons were reported as transferred to foreign flags during February.

From other sources than construction two vessels having a total of 8,646 gross tons were admitted to American registry.

Ship Bids Rejected

All bids received for the 1,490 Shipping Board vessels recently announced for sale have been rejected by the Shipping Board. About 100 bids were received in all and, according to a statement by Chairman Lasker, "there was not a serious bid in the whole lot." He spoke of them as facetious and declared that he was convinced there was no market for ships now and there probably would not be until the subsidy question now before Congress was decided.

Philadelphia Preparing to Spend Millions For Expansion of Its Pier Facilities; Bids Now Being Asked

The Department of Wharves, Docks and Ferries, Philadelphia, Pa., is soliciting bids which will be received and opened at 12 o'clock noon, March 24, 1922, for the construction of the superstructure of Pier No. 84, South Wharves, the substructure of which has already been completed at a cost of $1,292,202.76. The substructure is 300 feet wide and 900 feet long, and is of "solid fill" type; upon which will be placed three depressed railroad tracks in the center of the pier. The superstructure will be a two-story steel, and reinforced concrete structure and will cost approximately one and a half million dollars ($1,500,000).

Plans and specifications are now prepared and bids will be solicited some time early in the month of April for the construction of the superstructure of Pier No. 3, North Wharves, and the sub and superstructure of Pier No. 5, North Wharves. These piers are designed as combination piers for either the accommodation of Trans-Atlantic or coastwise and river traffic, each 185 feet wide by approximately 550 feet long, with all docks or waterways 215 feet wide, except that between the first pier, No. 3, and the ferry house, which will be 115 feet. The substructure will be of permanent and massive design and of the type known locally as the "fill-on-platform," which may be described briefly as timber piling supporting a timber deck covering the entire area of the pier near the low water level, and which in turn supports a dry fill deposited on the decking and brought up to the level of the main pier deck, and retained by concrete walls built on the low level decking along the sides and ends of the pier.

The superstructures will be two-story steel and concrete sheds of modern construction throughout, enclosed on the dock sides with an approved type of turn-over cargo doors and terra cotta tile walls, and will be thoroughly equipped with cargo masts, electrically operated elevators and winches, chutes, spiral conveyors and other improved cargo-handling apparatus. Double car tracks leading from the Philadelphia Belt Line Railroad in Delaware Avenue will extend into the sheds for nearly the entire length of the piers, and be depressed so that the car floor will be approximately at the same level as the pier main deck. The first deck will be designed for a loading of 600 pounds per square foot and the second deck for 300 pounds per square foot.

The facades of the pier and bulkhead sheds on Delaware Avenue and the river-end elevations will be architecturally treated in brick and lime stone, and when completed the Delaware Avenue front of the terminal, in conjunction with Cherry Street Pier (No. 9), to which it connects, will present an unbroken elevation, more than 1,000 feet long. The project will cost approximately three and a half million dollars ($3,500,000).

Contemplated Improvements

In addition to the above piers, the Department, will, before the end of the present year, enter into a contract for the construction of the superstructure of Pier No. 82, South Wharves, the substructure of which is now completed and cost $1,329,946.24. This substructure is 300 feet wide by 900 feet long, and is of the "solid fill type," and has been planned for two-story steel and concrete superstructure, with architectural concrete inshore and outshore elevations, with depressed railroad tracks in the center and along the outside of the sheds. The paving of River Street in front of said piers and the construction of a freight handling yard in the rear, the estimated cost of which is three million dollars ($3,000,000).

Private Work

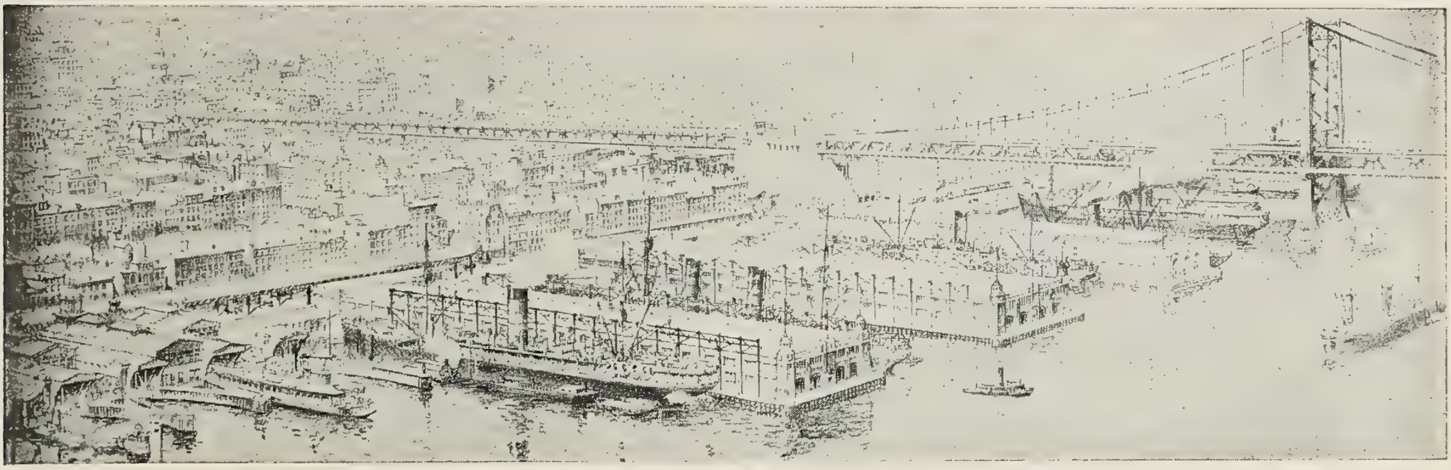
Licenses have been issued to private owners to construct work as follows:

S. B. Vrooman Company, Ltd., to erect a log pond and saw mill in front of their property situated on the Delaware River at Reynolds and Jenks Streets. Estimated cost, $150,000.

Philadelphia and Reading Railway Company, to install a new float bridge, and construct a mud fence in front of property on the Delaware River at Pier "J" Port Richmond. Estimated cost, $64,000.

And applications are now pending for: Philadelphia Electric Company, for the construction of bulkhead in front of their property situated on the Delaware River between Penn Treaty Park and Palmer Street.

Philadelphia and Camden Ferry Company, to construct one additional ferry rack at the foot of Market Street.



Proposed Girard Piers Nos. 3 and 5 North Delaware Wharves.

Seven New Boats Considered for Service in the East River

The City of New York will spend close to a million and a half dollars for new ferries for service in the East River, if present intentions are carried out. It is learned officially that engineers of the Department of Plant and Structures are preparing plans and specifications for at least two and probably seven vessels to ply in the East River. The boats will probably cost about $200,000 apiece.

It is understood that the type of ferry receiving consideration is to be of steel construction, 170 feet in length, the propelling machinery to be of the Diesel electric type. It will probably be several weeks before plans and specifications are available.

Water-Tube Boilers to Replace Scotch on Transport "Madawaska"

The new boiler installation of the United States Army Transport *Madawaska*, now being reconditioned at the yards of the Morse Dry Dock & Repair Company, Brooklyn, New York, will consist of six Babcock & Wilcox Water-tube, two-inch type, built for a working pressure of 250 pounds and having a total heating surface of 24,084 square feet. They will burn coal under forced draft. These boilers are so designed that they will occupy the boiler room space now taken up by the three double ended Scotch boilers in the vessel, the space taken up by a single ended boiler being added to the forward bunkers.

Diesel-Engined Yacht Contract Awarded Tebo Plant

A contract for the construction of a steel Diesel-engined yacht was recently awarded to the Tebo Yacht plant of the Todd Shipyards Corporation. This yacht is being built to the designs of Cox and Stevens for Merrill B. Mills of Detroit.

Her measurements are: 129 feet over all length, 23 feet beam, 6 feet 6 inches draft. The main propelling machinery will consist of two Diesel-type, six-cylinder, four-cycle Winton engines, each developing 225 brake horsepower.

The work of converting the auxiliary yacht *Alcyone* to Diesel electric propulsion is being completed at the same yard.

Marine Construction News of the Month

Ship Contracts — New Ship Concerns and Shipyard Improvements—Terminal Projects—Government Contracts

SHIPS AND SHIPBUILDING

Reconditioning Steamer, Hoboken, N. J.—Mongolia, of International Mercantile Marine Company, sister ship of Manchuria, is undergoing extensive reconditioning of her first class quarters at Tietjen & Lang plant. Work requires 60 days.

Pontoons, Tug, Coos Bay, Ore.—Port of Coos Bay has ordered four new pontoons for its suction dredge, and has started investigation to determine advisability of owning its own port tug.

Ore Carriers, Alameda, Cal.—Report from San Francisco stated that J. J. Tynan, vice-president and general manager of Bethlehem Shipbuilding Corporation, conferred with Charles M. Schwab regarding construction of new type of Diesel engine and building two 20,000-ton ore carriers.

Scows, Portland, Ore.—Port of Portland Commission let contract for construction of two donkey scows to Portland Shipbuilding Company at price of $1,650 each.

Reconditioning Job, Chester, Pa.—Steamship Columbia, formerly Great Northern, purchased from U. S. Government by Admiral Line, $1,250,000, and contract for reconditioning, same let to Sun Shipbuilding Company. Work will cost approximately $500,000, and includes extensive hull and machinery repairs and installation of accommodations for 675 first class passengers. Ship to be completed latter part of May.

Lake Freighters, New York.—Construction of fifteen lake freighters to cost close to $5,000,000 is contemplated by Central Steamship & Commerce Corporation, 30 Broad street. Plans and specifications for these boats, to be Diesel Electric, for service through Welland and New York Barge Canals, between New York and Chicago, and also to West Indies, when canal traffic is closed, are being prepared by Theodore D. Wells, naval architect and marine engineer, 11 Broadway. Preliminary plans call for special type ship, 257 feet long and equipped with Diesel engines developing 1,300 horsepower.

New Passenger Ship, Chester, Pa.—Sun Shipbuilding Company has been awarded contract for construction of 360-foot passenger steamer of 16½ knots speed, for Inter-Island Steam Navigation Company.

Conversion Work, New York.—Approximately a million dollars' worth of ship conversion work involving installation of Diesel engines in 11 vessels, of which 7 are steamers and 4 barges, is receiving serious consideration of Admiral Line. Conversion of steamers into motorships estimated at $100,000 each, and similar motive power in barges, $75,000 each.

Ferryboats, New York.—Engineers of Department of Plant and Structures are preparing plans and specifications for two and possibly seven vessels to ply in East River. Type of ferry said to be receiving consideration to be of steel construction, 170 feet in length and Diesel electric drive. Boats to cost about $200,000 apiece.

Lightship Overhauling, Jacksonville, Fla.—Lightship Relief LV-53 in dry dock at plant of Gibbs Gas Engine Company for repairs and general overhauling.

Repair Contracts, Baltimore, Md.—United States Shipping Board awarded contract for repairs to steamer Elmsport to Globe Shipbuilding Company at $11,183; steamer Hoxi at price of $6,887, and Meximus at $6,561 to Bethlehem Shipbuilding Corporation and steamer Bella at price of $2,625 to Obrecht & Company.

Vessel Overhauling, Winslow, Wash.—Winslow Marine Railway & Shipbuilding Company's plant at Eagle Harbor is repairing and overhauling local and coastwise vessels to be ready for spring season. Several vessels are awaiting their turn on the ways.

Steam Conversion, Vancouver, B. C.—Bids have been asked by Robert Dollar Company for conversion of steamer Cathay from coal into oil burner.

Ferryboats, New York.—Plans and specifications for construction of three electric drive steel screw ferryboats for operation between St. George, S. I., and Manhattan, have been submitted to Board of Estimate and Apportionment by Grover A. Whalen, Commissioner of Plant and Structures. They will be double-ended and 218 feet in length over all.

Diesel Engine Installation, San Francisco, Cal.—D. W. Dickie has plans for installation of 75-horsepower Enterprise Diesel engine on schooner Sequoia, owned by F. A. Watson, of Los Angeles.

To Enlarge Accommodations, San Francisco, Cal.—Shipping Board steamers Creole State and Wolverine State will have passenger accommodations enlarged to a capacity of 300 steerage, besides present complement of first cabin passengers. When completed vessels will ply in San Francisco-Manila route under flag of Pacific Mail Steamship Company.

To Be Oil Burners, Brooklyn, N. Y.—United Fruit Company steamers Carillo and Tivives are at plant of Robins Dry Dock & Repair Company for conversion.

Tanker Repairs, Fore River, Mass.—Bethlehem Shipbuilding Corporation is repairing steamer Clement Smith, of the Calvert Navigation Company, at price of $63,000 and 36 days' repairing under body, and $15,700 and 22 days for erecting new stern frame.

Overhauling Vessels, Oakland, Cal.—About 20,000 tons of Alaska Packer Fleet expected to be placed on the ways of the Moore Shipbuilding Company for general overhauling.

Repair Contract, Victoria, B. C.—Steamship Bessie Dollar awarded to Yarrows, Ltd., for repairs, $25,000 and 13 days.

Contract Award, Seattle, Wash.—British steamship Narenta severely damaged by grounding awarded Todd Dry Docks, Inc., $115,383 and 42 days.

Repair Activities, Newport News, Va.—Ships repaired here recently include Eastern Pilot and Standard Oil tanker J. A. Bostwick at Newport News Shipbuilding and Dry Dock Company, and Opria at Southern Yard.

Ship Overhauled, Brooklyn, New York.—United American Line steamship Dakotan awarded Robins Dry Dock & Repair Company for general repairs, $8,975 and 7 days.

Remodelling Gunboat, Newport News, Va.—Gunboat Nashville went to Southern Shipyard for conversion into 2,000-ton oil barge.

Barge Contract, Galveston, Texas.—Galveston Dry Dock Company awarded contract for reconditioning and repair of collision damage to Sinclair Oil Company barge, $41,500 and 60 days. Bids opened February 27 at New Orleans, La.

Big Repair Job, New York.—Shipping Board steamships American Legion and Southern Cross awarded Staten Island Shipbuilding Company for reconditioning. Total price about $144,750.

Plate Replacements, Buffalo, N. Y.—Buffalo Dry Dock Company active, recent jobs including renewals and repairs on steamers J. S. Ashley, W. P. Palmer, the Robinson, the Bedell, and the Newton.

Stern Wheel Steamer, Vancouver, B. C.—G. F. Askew reported to have order for stern wheel steamboat, 172 feet in length, for Hudson Bay Company service.

Hulls for Barges, Portland, Oregon.—Port of Portland reported negotiating with Shipping Board for purchase of three wooden hulls now lying in that harbor.

SHIPYARDS AND DRYDOCKS

Shipyard Closed, Clearfield, Md.—Plant of the Union Shipbuilding Company near Curtis Bay has been closed down and is in charge of caretakers. Company is owned by McClintock & Marshall, Pittsburgh, Pa.

Dry Dock, Elizabeth City, N. C.—Elizabeth City Iron Works, Riverside Ave., contemplates construction of a dry dock and marine railway in addition to machine shop.

Shipyard Sale, Bristol, Pa.—Shipping Board has placed plant of Merchants' Shipbuilding Corporation on sale. Yard has twelve shipways for building 400 foot steel ships and cost about $10,000,000.

Ship Repair Plant, Mobile, Ala.—Todd Shipyards Corporation, Wm. H. Todd, president, 25 Broadway, New York, plans construction of dry dock, shipbuilding and ship repair plant on recently acquired property on which plant of Mobile Shipbuilding Company was formerly located.

PORT IMPROVEMENTS

Pier, Weehawken, N. J.—Erie Railroad, 50 Church street, New York, has let contract to Foley Brothers, 209 Gilfillan Building, St. Paul, Minn., rebuilding one of four piers recently destroyed by fire; $1,000,000.

Pier, Bay St. Louis, Miss.—W. W. Hammons, Gulfport, Miss., has contract for construction of public ferry pier connecting Hancock with Harrison County.

Wharf, Etc., Miami, Fla.—Bakers Haulover Commission, J. C. Baile, chairman, will construct inlet or channel between Atlantic Ocean and Biscayne Bay, Dade County; about $250,000. Robert Crabtree, engineer.

Terminals, Portsmouth, Va.—City Manager Jervey contemplates construction of municipal terminals. U. S. District Engineer J. C. Oakes interested in project.

Wharf, Etc., St. Petersburg, Fla.—City plans improvements to Bayboro harbor, including deepening to 18 feet and building of 600-foot wharf. $100,000 bond issue contemplated. Address the Mayor.

Piers, Philadelphia, Pa.—Contracts for construction of Girard piers, to be built of concrete and to replace obsolete wooden structures, will soon be let; about $4,000,000.

Pier Extension, Tacoma, Wash.—Port Commissioners plan 400 foot extension to Pier 1, to limits of port property.

Harbor Works, Tampa, Fla.—The city will vote not later than May 2 on $600,000 bond issue for complete improvements on the Ybor estuary waterfront.

Improvements Sought, Gulfport, Miss.—State representative, Houston H. Evans, reported interested in an appropriation of $80,000 for harbor improvements.

Seawall, Greenville, Miss.—Delta Cement Tile Company awarded contract for construction concrete and steel seawall, $184,000.

Wharves, Orange, Tex.—City reported as having sold $240,000 bonds for construction and equipment of 800 feet of additional wharves.

Harbor Improvements, Houston, Tex.—The city has $26,440 available for improving and maintaining its harbor. Address the mayor.

Wharf and Ferry Building, Philadelphia, Pa.—Plans completed for two story ferry building and wharf at Larners Point for the Tacony Ferry Company to cost about $100,000.

Municipal Pier, Mich.—Village council at Grosse Pointe Farms, Mich., contemplates municipal pier to cost about $45,000.

GOVERNMENT WORK

Dredging, Nashville, Tenn.—War Department, Lieut. Col. J. R. Slattery, Box 900, will spend about $15,000 for dredging between municipal terminal and channel proper, Cumberland River.

Dredging, Philadelphia, Pa.—Delaware Dredging Company, Colonial Trust Building, has contract for dredging in Murderkill River and Inland Waterway between Rehoboth and Delaware Bays; $45,700.

Tug Boat, Washington, D. C.—Sealed proposals received until 10:30 A. M., April 17, for purchase of tug boat being offered for sale by General Purchasing Officer, the Panama Canal, Washington, D. C. Circular 1471.

Contract Awards, Washington, D. C.—Bureau of Yards and Docks, Navy Department, awarded contract to Wittenmeier Machinery Co., 650 North Spaulding avenue, Chicago, Ill., for installing refrigerating and cold storage plant at Naval Base, San Diego, Cal., at price of $29,970, and to General Electric Company, Schenectady, N. Y., for installation of motor generator sets and switchboard at Naval Base Hospital, Hampton Roads, at $16,860.

Specifications.—The following specifications have been available at or in contemplation by the Bureau of Yards and Docks, Navy Department, Washington, D. C., for various work or material as listed below:

Hangar, Etc., San Diego, Cal.—Construction of hangar and oil storage house. Specification 4581.

Guardhouse, Etc., San Diego, Cal.—Quartermaster guardhouse and shops at marine corps. Specification 4582.

Equipment, Boston, Mass.—Installation of coal handling equipment. Specification 4583.

Radio Quarters, Sayville, N. Y.—Construction of radio quarters. Specification 4584.

Equipment, San Diego, Cal.—Installation of mess and kitchen equipment. Specification 4587.

Shed, New York City.—Construction of steel storage shed on Pier H. Specification 4589.

Wharves and Piers.—The United States Government Constructing Quartermaster is preparing plans for the construction of wharves and piers at Fort Mason, Cal.

Dredging Contract, Jacksonville, Fla.—J. C. Angier, Miami, Fla., awarded contract for dredging and rock removal at Sarasota Bay, Fla., $59,588.

Tugboat, Panama Canal.—General Purchasing Officer for Panama Canal will receive sale proposals at Washington, D. C., until 10:30 A. M., April 17, for purchase of one tugboat being offered for sale.

NEW INCORPORATIONS

Interlake Navigation Company, Ltd., Montreal, Canada; capital, $500,000; to own, operate ships of all kinds, wharves, docks and general transportation facilities and to carry on general navigation and forwarding business; W. W. Skinner, G. G. Hyde, J. F. Ahern, R. C. Grant and R. J. Forster.

Empire Shipping Corporation, Wilmington, Del., capital $100,000; to build, own and operate boats.

Glen Steamships, Ltd., has been incorporated under the Dominion Companys Act with $1,000,000 authorized capital and an office at Midland, Ontario, to carry on a business of transportation of merchandise, grain, coal and passengers; all land and water towing, wrecking, and salvaging in all its branches; to own and operate ships of all kinds, wharves, piers, docks, shipbuilding yards and general transportation facilities. The incorporators are James Playfair, president and general manager Great Lakes Transportation Company; D. L. White, D. S. Pratt, J. W. Johnson and F. W. Grant, Midland, Ontario.

The Monmouth Steamship Company, Ltd., has been incorporated under the Dominion Companys Act with $100,000 authorized capital, to own and operate ships, dry docks, shipping terminals and other transportation facilities, and to carry on a general navigation business. Office at Toronto.

FOREIGN ACTIVITIES

Minelayer.—Werf Gusto, A. F. Smulders of Schiedam, Holland, has launched a steel hull of the Dutch minelayer Douwe Aukes, which is under construction for the Royal Dutch Navy and which is the last of two such vessels under construction in that yard. The steamer will be provided with two triple expansion engines, two water-tube boilers and have a speed of 13 knots. She will be fitted with all modern equipment.

New Motor Ships.—The 14,000-ton motor ships Lochkatrine and Dinteldyk, for the Royal Mail Steam Packet Company and the Holland Amerika Line, respectively, were completed in February by Harland & Wolff. These ships inaugurated a new service to be developed by the steamship line between England, Dutch ports, and the west coast of North America. The vessels will be followed by four similar craft, all built especially for this trade by the same shipyard, two to sail under the flag of the Holland Amerika Line and two for the Royal Mail Steam Packet Company.

Program of Motor Ships.—Construction of motor ships abroad continues active. It is reported that the Glen Line program, now in hand, when completed will give a fleet of four 1,400-ton ships and about eight or nine vessels of 10,000 tons. The British India Company has a program of five motor ships of which only the first has been completed. Holts are building two motor ships, Furness, Withy & Company have recently taken delivery of their first vessel, and two more are on order, while Tankers, Ltd., will shortly be in possession of four motor tankers.

Maiden Voyage.—The motor ship Glengarry, the third 14,000-ton standard Diesel motor ship built for the Glen Line by Harland & Wolff was scheduled to sail on her maiden voyage from London on March 23.

Sea Trials.—The Doxford-engined motor ship Dominion Miller, the 9,300-ton vessel for Furness, Withy & Company, recently completed her sea trials. She is equipped with 3,000 indicated horsepower opposed-piston engines and averaged 12.2 knots on her trip. After completing her trials the ship left on her maiden voyage to Buenos Aires.

Southampton Harbor Dredging.—It is announced that the Southampton Harbor Board has accepted the tender of Messrs. James Dredging & Towing Company for the dredging of the swinging ground and the deep water channel, which work is being carried on with a view to the reception abroad of deep draft vessels engaged in the Transatlantic service. It is expected the work will be completed within four months.

Launching, England.—On March 1 a new steel-screw steamer was launched from the Southwick yard of Swan, Hunter & Wigham Richardson, Ltd., to the order of the Cork Steamship Company, Ltd., for their line trading between Manchester and Liverpool and Dutch and Belgium ports. The vessel is 290 feet in length by 42½ feet beam, and is designed to carry over 3,100 tons dead weight on a light draft of water. The ship will be propelled by a set of triple expansion engines, which with the boilers are being constructed at the Neptune Works, Newcastle-on-Tyne, of Swan, Hunter & Wigham Richardson, Ltd.

Repair Contract, Rotterdam.—The contract for repairing the steamship Turkestan, which stranded recently at Breaksea Point of the Bristol Channel, has been awarded to the New Waterway Shipbuilding Company, Rotterdam. About forty bottom plates were to be renewed. The steamer Fifetown, which stranded at the same place, was awarded to Robb & Co., Leith. Nearly a hundred bottom plates were to be renewed on the latter ship.

New Lighter, Holland.—Mr. G. Gammers, at Osoterhaut, has ordered from N. V. Scheepsbouwwerven v/h P., and A. Ruytenberg, Waspek, a river lighter with a dead weight capacity of 1,050 tons.

Tonnage Output, Clyde District.—Shipyards on the Clyde during the month of February launched only a small number of vessels, the total tonnage being only about a third of that launched in January. The output from February consisted of six vessels of about 20,500 tons, as compared with twenty-five vessels of 82,500 tons in February of last year. The total for the first two months of 1922 consists of 16 vessels of 79,000 tons.

Anchor Line Ships, Clyde District.—Three large passenger ships will go on the Anchor Line in the service between Glasgow and New York within the next few months. The Columbia is at present being overhauled at Glasgow in preparation for the opening of the service, and at the same time is being fitted for oil burning. The Cameronia, which was completed last year, has been refitted at Glasgow during the past two months. A third vessel, the Tuscania, is now being fitted out at Glasgow for the New York service beginning next June, while a fourth vessel, the California, now under construction in the yard of Alex. Stephen & Sons, Linthouse, is expected to be launched soon. Two other vessels, the Transylvania and the Caledonia, are also building, but completion has been delayed

New Crane, Scotland.—Swan, Hunter & Wigham Richardson, Ltd., have purchased from a Dutch firm an improved type of crane with a lifting capacity of 150 tons to replace the Titan, which sunk near Jarron Slake as a result of a severe gale on December 17.

Tyne Ship Repairing.—More activity in ship repairing on the Tyne is reported due to the greater demand for tonnage for the coal export trade.

Repair Contract, Liverpool.—The contract for repairing the Cardiff steamship Euterpe, 6,000 tons, which sustained extensive bottom damage through grounding on the Tuskar Rock, has been awarded Messrs. H. & C. Grayson, Ltd. About 60 bottom plates are to be dealt with, in addition to frames, etc., and it is estimated the work will take a month to five weeks. The steamer is at Cardiff at present.

Shipbuilding Wages.—It is anticipated that the ballot which is now being taken of the shipbuilding unions in Great Britain, on the proposals of employers to discontinue the war bonus of 26 shillings 6 pence (approximately $6.44 at the normal rate of exchange) in two stages, namely 16 shilling 6 pence ($4.00) on March 15, 1922, and the other 10 shillings ($2.43) at some later date to be arranged mutually, will disclose a hostile vote. The employers have intimated to the Union that in any event a cut of 26 shilings 6 pence will be made on March 15, and it is therefore anticipated that a complete stoppage in the shipbuilding industry will take place.

Ship Construction, Germany.—It is announced that prospects for German motor shipbuilding for the immediate future are decidedly better. At the opening of the current year several motor ships were on the stocks at various German shipbuilding centres, and anticipations are that before the year has expired, about ten motor ships of large size will have been completed and delivered. The greater number of these vessels are being produced by the Deutsche Werft Aktiengesellschaft, of Hamburg. Altogether, there are at the present time about 20 motor ships of large size known under construction at German yards for German account, the exact number not being known.

New Tanker Fleet.—Phero, the fifth of the 500-ton motor-tankers built to the order of the Anglo-Persian Oil Company, has been completed by Crichton-Thompson Company. In each vessel a 180 brake horsepower Kromhout surface-ignition oil-engine is installed.

Sailing Ship Being Converted.—The sailing ship Scala Shell, of 4,500 tons d.w., is being equipped in Holland with two 800 shaft horsepower Vickers submarine-type Diesel engines, to the order of the Anglo-Saxon Petroleum Company.

Motorship in Service.—The motorship Munsterland, sister to the Haveland, recently ran trials and started on her maiden voyage to the Far East. Both these vessels have high-powered German submarine Diesel engines, driving propellers through reduction-gears, and are owned by the Hamburg-American Line.

New Ship.—One of the most interesting orders of 1922 is that embodied in the contract just placed by Alfred Holt & Co., Liverpool, England, with the Scott Shipbuilding & Engineering Company of Greenock, Scotland. This consists of a twin-screw motorship of 400 feet length, 52 feet breadth, and 32 feet depth, to be propelled by two 1,250-shaft horsepower. Still combination oil-and-steam engines.

STEAMSHIP INTERESTS

If present plans of the Baltimore Steamship Company materialize, the company will operate steamers from New York, as well as from Baltimore and Philadelphia, to Glasgow and other United Kingdom ports. It is probable that the company may operate Shipping Board steamers from New York to Irish ports.

In anticipation of increased business between the United States and the Irish Free State, the Irish-American Line, 82 Beaver Street, New York, has been incorporated under the laws of Delaware with a capital of $500,000. The new company is reported to be negotiating for the purchase of two vessels for passenger and freight service.

According to McCormick, McPherson & Lapham of San Francisco, Cal., general agents for the Osaka Shoshen Kaisha, this Japanese company will soon inaugurate an around the world freight service to be known as the Calcutta-New Orleans Line. The vessels will make the trip in four months, and in order to maintain a monthly service, four vessels will be operated.

A. H. Bull & Company of New York, have announced a new direct service between Boston and ports on the West Coast of Africa. There will be monthly sailings. C. H. Sprague & Son are Boston agents for the line.

The Norton Line, through its general agents, Norton, Lilly & Company, announces a reduction in passenger fares for the steamship *Crofton Hall,* sailing April 25 for Montevideo and Buenos Aires. Rates for Montevideo are from $225 to $500 and for Buenos Aires $250 to $525. The *Crofton Hall* carries first class passengers only.

Latest indications at Tacoma, Wash., are that the Nawsco Line will enter the passenger trade with several vessels that this line has been considering. These contemplated craft will be combination freight and passenger ships.

The United States Lines have announced the installation of one-cabin service between New York, Queenstown, Cherbourg, Southampton and London to be inaugurated with the sailing of the *Panhandle State, Centennial State* and *Old North State,* these ships to be shortly augmented by two others. The conversion of these "State" vessels for the new service involves merely the addition of two berths above the present hotel beds, thus giving accommodations for four instead of two persons.

According to the International Mercantile Marine Company, a direct service between Germany and Canada will be instituted this Spring with the sailing on April 23 from Halifax of the third-class liner *Vedic* for Bremen. Later sailings of vessels in this new service will be made from Montreal.

BUSINESS NOTES

The Pyle National Company announces that Mr. J. D. Sarles, of the marine department, will have temporary headquarters, until further notice, at Hotel Chelsea, 23rd Street and Seventh Avenue, New York.

The Wager Furnace Bridge Wall Company, Inc., announces the removal of its offices at 149 Broadway, New York, to new and enlarged quarters at the plant, 108-110 Academy Street, Jersey City, N. J.

The Dollar Steamship Line has announced the removal of its offices from 44 Whitehall Street to the International Commerce Building, 11-15 Moore Street, New York.

The Luckenbach Steamship Company, Inc., has announced the opening of an office in the Board of Trade Building, 131 State Street, Boston, Mass., in charge of K. E. Hurlburt, acting local manager.

The present Board of Directors of The Norwalk Iron Works Company, South Norwalk, Conn., announce a number of changes in the executive personnel of the organization. The executive staff is now as follows: C. L. Thompson, president and general manager; Howard E. Adt, first vice president; Harold B. Knowles, treasurer and asst. secretary; Thomas M. Steele, secretary; A. R. Betts, vice-president in charge of sales; W. E. Mathews, vice-president in charge of manufacturing and engineering; G. W. Wardwell, chief engineer; W. M. Greene, general supt.

The firm of Cox & Stevens, naval architects and marine engineers have moved their offices from 15 William Street to 25 Broadway, New York.

The Sun Shipbuilding Company, with its subsidiary, the Opposed Piston Oil Engine Company, of Chester, Pa., announces the opening of their New York office, Room 710, Cunard Building, 25 Broadway. The company is engaged in the construction of all types of vessels, ship repairs and dry docking, and the re-engining with steam or Doxford Diesel engines.

The Diamond soot blower business has been purchased by new interests in the form of the Diamond Power Specialty Corporation of Detroit, Mich., a new company which has taken over the business and plant of the Diamond Power Specialty Co., co-partnership, the members of which are retiring from the soot blower business in the Western Hemisphere. Norman L. Snow, president and treasurer of the new company, resigns his position as vice president and active head of the Terry Steam Turbine Co. of Hartford, Conn., with which he has been connected for the past thirteen years.

TRADE PUBLICATIONS

Gasoline Power Units.—The Buda Company, Chicago, has issued bulletin No. 388, describing a four-cylinder gasoline power plant, which it has recently developed for use in driving electric generators, arc welding sets, triplex or other types of pumps, hoists, concrete mixers, air compressors and for similar uses in machine shops, etc.

Generator Cooling Apparatus. — The B. F. Sturtevant Company, Boston, Mass., has issued Bulletin No. 246 describing and illustrating in detail its generator cooling apparatus. A psychrometric diagram showing the percentage of relative humidity has also been included in the bulletin which contains 27 pages.

Pipe Machines.—Stoever pipe machines for cutting and threading steel or wrought iron pipe are illustrated and described in a neatly arranged booklet of 16 pages recently issued by the Treadwell Engineering Company, Easton, Pa.

Cutting Torches.—The Air Reductions Sales Company, New York, features its type "D" cutting torch in a new folder now being distributed. In addition to an illustrated description of the torch, the leaflet contains tables of metal thicknesses that can be cut, oxygen and acetylene pressures necessary and the gas consumption in cubic feet per hour when using tips adapted to steel, cast iron or rivet cutting.

MARINE SOCIETIES

AMERICA

American Society of Naval Engineers

WE GUARANTEE that of this issue 5,550 copies were printed; that of these 5,550 copies 4,149 were mailed to regular paid subscribers, 337 were provided for counter and news company sales, 216 were mailed to advertisers, 27 were mailed to employees and correspondents and 821 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 27,350—an avrage of 5,470 copies a month.

MARINE ENGINEERING AND SHIPPING AGE is a member of the Associated Business Papers, Inc. (A. B. P.), National Association of Periodical Publishers, Inc., New York Business Publishers' Association and the Audit Bureau of Circulation (A. B. C.).

Requests for change of address should reach us two weeks before the date of the issue with which it is to go into effect. It is difficult, and often impossible, to supply back numbers to replace those undelivered through failure to send advance notice. In sending us change of address, please be sure to send us your old address as well as the new one.

A Prophecy

THE Merchant Marine Act of 1922, with its direct and indirect aids will become a law during this session of Congress for the following reasons: The country is sold on the proposition of an American merchant marine; the necessity for the immediate adoption of a definite shipping policy which will induce private capital to invest in American vessels by giving American ships a chance to compete with foreign vessels on all fours is apparent; sufficient demand, which is as essential as necessity when legislation is to be secured, exists; the bill itself has been worked out on such a conservative and comprehensive plan for encouraging shipping, while at the same time safeguarding the Treasury, that no one has been able to accept the President's invitation to suggest something better.

That the country is sold on a merchant marine is evident from the public endorsements that the Shipping Bill has received from chambers of commerce and trade organizations in the South and Middle West. The testimony of representatives of these organizations who attended the hearings at their own expense for the purpose of informing Congress of their sentiments shows that the country is determined to preserve the trade routes that have been established by the Jones Act. They want a guaranty that American vessels will be kept on these routes for at least five years, and they never again will be willing to risk a congestion in transportation by depending on foreign ships for the carriage of their surplus products.

The necessity for an American merchant marine which Congress recognized in the preamble of the Jones Act when it promised to do whatever was needed to establish American shipping on a basis that would serve the country adequately in peace and war has been acknowledged even by such subsidy opponents as Senator Fletcher. Senator Fletcher stated in an address before the convention of the National Merchant Marine Association that he would support the Shipping Bill, if he could be shown that a subsidy was necessary in order to establish an American merchant marine. The democratic members of the Senate and House committees on merchant marine affairs are cross-examining witnesses in a very exhaustive manner, perhaps in the hope of delaying action until they can make alternative suggestions, but yet fully realizing the fact that a definite shipping policy will have to be adopted.

The demand for this legislation is indicated by the change in editorial policy of several influential Middle West newspapers, by the earnest efforts of 14 States to secure an outlet from the Great Lakes through the St. Lawrence River, by the determination of the Mississippi Valley Association representing 28 States to secure an outlet for agricultural products through the Gulf, by the growing realization of the importance of the merchant marine as a naval reserve and by the efforts of the President himself whose fondest wish is to establish the merchant marine in his administration.

British Propaganda

IT is the firm belief of a great many men of unquestionable integrity that active British propaganda is constantly at work to prevent the proper development of an American merchant marine. This is a fact, and it is chiefly due to the character of the shipping editorials appearing in a large percentage of the American press and notoriously many of those of New York city which have consistently opposed any constructive legislation that would establish our merchant fleet on a profitable basis.

On many occasions the *New York Journal of Commerce* has been open to suspicion on this account but the editorial recently appearing in their columns entitled "Government and Shipowners Incorporated" exceeds in *inaccuracies* and attempted sarcasm anything that has come to our attention. One would think that, if London papers could interpret the Shipping Bill in March, the *Journal of Commerce* ought at least to be able to do it in April, especially in view of the

able analyses that Mr. Lasker and others have publicly made and which have been literally broadcasted to the press.

This editorial in referring to subsidies says, "It is intended to pay subsidies to vessel owners, who will then carry on business as best they can. In the event that they are successful in making profits above 10 percent, one-half the surplus will constitute a repayment to the subsidy fund. In order to establish the conditions under which the shipping business is carried on, there is thus necessitated an extensive system of accounting and reporting, with allowance for depreciation and the like. This is obviously essential, if there is to be avoidance of concealment of profits or error in the reporting of apparent losses. Such a system of accounting and reporting would require clearly as elaborate a method of segregation as would be essential in any private business."

To comment on this for the benefit of our readers, we take pleasure in explaining to the *Journal of Commerce* that the profit a ship operator makes in excess of 10 percent will be determined by his *income tax return* which will have to be made and audited, subsidy or no subsidy. Chairman Lasker has repeatedly explained that the few hundred ship operators' returns ought not to embarrass the Treasury department who are handling far more complicated questions than checking a ton mileage subsidy with a net income statement. As there is very little likelihood of many, if any, companies making over ten percent, it would appear that there is no occasion to worry about the reliability of the income tax returns. If there is, we have failed to note any anxiety from the press about the taxes that the Government may be losing through the possibility of millions of income tax returns being incorrect. It is conceded that a small number of reporters will be needed to determine the subsidies to be paid by multiplying a fixed speed times a fixed tonnage times a fixed distance at a fixed rate.

The next statement made in this editorial relates to loans to shipowners and it reads as follows: "Obviously, if the Government should go into such an enterprise, it would be a kind of special partner. It would in the first place be a large creditor of the buyers of vessel tonnage, who are expected to purchase on perhaps 15 years' credit. Since the loans are to be made at a nominal figure of possibly two percent either for the carrying of the unpaid sums due on the ships or for furnishing working capital (where that is allowed), the Government will of course have very scant security and will find it needful in any case to keep close track of the methods of operation."

In commenting on this, we utterly fail to understand how our esteemed contemporary, if it has actually taken the trouble to read the proposed law, *could mix up the construction loan fund with the sale of existing vessels and unpaid balances.* In this case, for its information, the proposed law only allows money to be loaned at 2 percent when it is to be used in the construction of special types of vessels, such as passenger vessels, refrigerator ships or motorships which are sorely needed to balance the fleet. Mr. Lasker testified before the hearings that he would not sell the Government vessels without a substantial payment down and that the unpaid balance would draw a commercial rate of interest. Where does the scant security come in on selling vessels at about $30 on such a basis?

After indulging in a few pessimistic inferences regarding the future of the American merchant marine, this patriotic expounder of our shipping policy enumerates what it calls the adventitious (accidentally or casually acquired) indirect aids. It then expresses great concern as to the possible effect that the carrying out of such policies would have on other nations.

The *Journal of Commerce* knows that the Shipping Bill was prepared from the facts and findings of well known marine experts working in conjunction with the Shipping Board. It must also be aware that when the President outlined the exhaustive and comprehensive nature of this proposed legislation, he said if anyone has criticisms to offer of this plan *they should at least suggest something better in its stead.* How then can a daily newspaper supposed to be serving the shipping interests, forty-nine days after the Shipping Bill has been introduced into both Houses of Congress, publish an editorial 16½ inches long without one constructive suggestion and sarcastically criticise the provisions of this bill by basing its logic upon inaccurate statements of the intent of the proposed legislation? This may not be British propaganda but it certainly is not American.

American Marine Association Active

THE American Marine Association, born some fifteen months ago and at the beginning known as the Marine Equipment Association of America, has made rapid strides as a factor in the marine field. Originally it was intended that the chief function of the organization should be to stage an annual marine show; but by degrees its scope has broadened until now it is rapidly assuming the proportions of a chamber of commerce.

The first definite step toward the present goal was taken last year when the association decided to hold its initial exhibit during the week in which the Society of Naval Architects and Marine Engineers held its annual meeting and succeeded in enlisting the hearty cooperation of that organization, which it still enjoys. This was followed in turn by agreements on the part of the American Society of Marine Designers and American Steamship Owners' Association to participate in the efforts of the American Marine Association, made last November, to inaugurate "American Marine Week;" while the Technical Committee of the American Steamship Owners' Association gave its approval by visiting the marine show in a body. Efforts are now being made to enlist the support of other similar bodies.

Following the first get-together in November, the American Marine Association immediately took steps to capitalize its work by revamping its committees, opening a permanent office in New York and renting two floors of the Grand Central Palace for its second annual exhibition (November 4-11), for which it has already booked considerable space. During these activities the association has found time to carry on a campaign for increased membership and perfect arrangements to help to stimulate public interest in the subject of an American merchant marine.

In connection with the last mentioned activity, the association has endorsed President Harding's plan and is taking steps to make its action known to Congress. The opinion

of the American Marine Association will undoubtedly have considerable weight with those charged with enacting legislation that will mean much to American shipbuilding and shipping, since its membership includes substantially all of the large and many of the smaller American concerns having to do with building and repairing ships and manufacturing the things with which ships are equipped, as well as a number of steamship operating companies whose vessels fly the American flag.

The Proposed Pacific Steamship Combine

ACCORDING to Mr. Lasker's testimony at the hearings on the Shipping Bill, the real object of the board, in suggesting at the time that it did to the shipping and financial interests of the Pacific Coast that a steamship combination having a capital of at least from $25,000,000 to $30,000,000 should be formed to meet the competition of the strongest companies of other countries, was to obtain data and facts from men representing the wealth of the Pacific Coast which could be recited to Congress and which would show a definite case where the passage of the proposed shipping legislation would bring immediate results.

The fact that a group of representative men could be induced to travel across the country to Washington to confer on the possibilities of a shipping combination of this sort, knowing, of course, that it would be several months before a definite shipping policy could be established, ought to be a practical assurance to the American people that results can be obtained.

There are several reasons why the Pacific offers exceptional opportunities for a large company operating combined passenger and cargo ships, provided the President's plans go through. Principally among these are the proposed diversion of the Army transport service to private vessels and the extension of the coastwise regulations to include the transportation service to the Philippines.

At any rate the committee from the Pacific Coast was so much impressed with the possibilities of a great American steamship line on the Pacific that its members were disappointed that the Shipping Board could not make them a definite proposal at the time. The board, however, obtained its object, for the committee voluntarily averred that it would go ahead and form this big steamship company, if the proposed legislation or approximately the proposed legislation is enacted by Congress. They are entirely disinterested, if it is not.

Insurance Syndicates Report

CONSIDERING the depression in business, the fall in tonnage values and the increased competition of foreign companies, the annual statement of the American Marine Insurance Syndicates is very satisfactory. Although Syndicate "B" has done very little business, due to the inability of the Shipping Board to dispose of its vessels, it reports a credit balance of $477,066.74.

The scope of Syndicate "B" is limited to insuring the unpaid balances on Government ships and these vessels cannot be sold except at very low prices, which complicates the question of making good the cost of repairs. In addition to this, the managers have recently agreed that "where a private owner's interest is written in Syndicate 'C' the same rate will be quoted in 'B' for the Government's interest;" where a private owner's interest is placed with underwriters other than "C," Syndicate "B" will quote for the Government's interest the same rates as would have been quoted for the owner's interest if insured with Syndicate "C"; and "that all obligations to place such insurance with 'B' being suspended and the Government and owners being at liberty to place the insurance in the world market if so decided in each case by the Shipping Board."

Syndicate "C" reports a credit balance of $1,251,597.35 which, in view of business conditions, reflects very efficient management. In one instance, the fact that the managers refused to meet the market on the terms offered for insuring the *Northern Pacific,* whose total insurance amounted to $1,250,000, resulted in the absorption of the total loss by foreign companies.

Syndicate "A," or the United States Salvage Association, reports the practical completion of a world wide organization having agents at 88 ports. The work of this syndicate in making damage surveys, assisting in salvage work and other functions similar to those practiced by the London Salvage Association, should be of great benefit to our merchant marine as well as marine insurance companies.

Keep the Navy Properly Manned

THE United States was able to call a Disarmament Conference and to succeed in getting the principal maritime powers to make a treaty ending the mad race for naval supremacy simply because it had an efficient Navy and the potential power of increasing the number of its warships far beyond that which any other nation could do without involving itself in serious financial difficulties. If America had not been powerful on the sea or if she had not been able to sacrifice much more than any other country in the way of naval strength, it is very doubtful whether this long step toward the attainment of a permanent peace could ever have been accomplished.

Why, then, after telling the world that a certain tonnage of capital ships represents an irreducible minimum that this country cannot safely go below, should Congress attempt to reduce the naval personnel to 67,000 when it was stated at the time of the conference that 130,000 men were required to efficiently man our ships on the so-called 5-5-3 ratio? At this writing the House has increased the number of men to 86,000 which is no more nor less than a compromise. As the personnel has to do the fighting an adequate number of trained men is more important than a paper figure of displacement tonnage. Does Congress wish to create the impression that we are going to scrap our Navy anyway, that we made no sacrifice in giving up our best ships, and that other countries have been inveigled into an agreement, our part of which we intended to do notwithstanding the result of the conference?

If such is the case, our legislators certainly do not realize the fact that the Limitation of Armament agreement is only

an experiment at the best. All thinking men know that the danger of war is not passed but simply reduced. They know that the best insurance not only for this country but for the world against a recurrence of armed conflict lies in the United States preserving a strong influence, backed by reasonable naval power which can be exerted in the proper direction when critical situations arise, as they surely will.

Financing and Expanding Our Foreign Trade

FINANCING and expanding our foreign trade, which will be the principal theme at the ninth National Foreign Trade Convention to be held at Philadelphia, May 10, 11 and 12, is of even more importance to the welfare of our merchant marine than the passage of the shipping bill.

The shipping bill will equalize the differential existing between the cost of operating American and foreign ships but it will not provide the cargoes that must fill these vessels if they are to be profitably employed.

Fortunately, however, America can easily produce more than enough to fill even our surplus cargo ships and by so doing it could increase the purchasing power of our citizens so that they could import an ever increasing amount of the products of other nations.

Just as a man who is able to successfully direct a business enterprise that gives profitable employment to a large number of people is a public benefactor, so America could, by financing and expanding its foreign trade on sound business principles, furnish an opportunity for other nations to increase their production, develop their industries and improve their standard of living.

The loss of productive and purchasing power of the several million men who were slaughtered in the world war was a terrible blow to the world's economic structure, but that cannot be helped now. What can be helped on our part is a restriction of production to domestic needs with its consequent unemployment, reduced purchasing power and inevitably lower standards.

It is to be hoped that the Foreign Trade Convention will find a solution of the problem of European credits. Several schemes have been proposed and constructive legislation in the Edge Act has been accomplished, but there remain in South America and the Orient enormous opportunities that have as yet only been scratched.

Japan has spent vast sums of money in this country, which has been of mutual benefit. The insistence of our statesmen that the policy of the "Open Door" shall be maintained is sufficient proof of the value and possibilities of this market. Until the standards in the Orient have been raised to somewhere near our own level the only reason for over production is the lack of brains and courage to direct the development and resources of such countries as China so that the purchasing power of her citizens will be sufficient to allow them to avail themselves of what we consider the necessities of life.

This means the establishment of foreign merchandizing and banking branches on a firm footing and this must be accomplished, if a real merchant marine is to be established and an outlet for our surplus agricultural and manufactured products maintained.

Shipping Board Experts Who Prepared the Ship Subsidy Bill, the Basis of President Harding's Message to Congress and the Legislation Now Pending

Back row, left to right—Rear-Admiral H. H. Rousseau, U. S. N.; Winthrop L. Marvin, vice-president and general manager, American Steamship Owners' Association; John Nicolson; Captain E. E. O'Donnell; T. H. Rossbottom; Daniel H. Cox. Front row, left to right—Captain Irving L. Evans; Rear-Admiral C. S. Williams; Meyer Lissner, commissioner United States Shipping Board; Albert D. Lasker, chairman United States Shipping Board; Elmer Schlesinger; N. B. Beecher; J. B. Small, R. T. Merrill and Dr. S. S. Huebner.

Let's Have Protection All Along the Line

By Winthrop L. Marvin

Protection, vigorously applied and adhered to, has made the United States the greatest manufacturing nation in the world. It has the power —as our foreign rivals know full well—to make the United States the foremost ocean shipping nation as well.

It is well that President Harding's new Shipping Bill comes forward in a Congressional session that is called on to enact also a new protective tariff. This serves to emphasize the fact that national aid is not asked alone for our ocean shipping industry.

What the protective policy has proved to be for manufacturing and for agriculture the Shipping Bill, with its indirect aids and direct compensation, or subsidy, will also be for shipowning and shipbuilding. The two measures naturally and logically go together.

The First American Tariff Protected Shipping

In fact, the very first protective tariff in American history —the law of July 4, 1789, the first law under the Federal Constitution—gave powerful aid to ocean shipbuilding and navigation along with all other American industries of the day. That law fixed a substantial rate of import duty upon virtually all kinds of foreign merchandise, and protected the shipowners, shipbuilders and seamen by a provision that there should be a higher duty by 10 percent on these foreign goods in foreign ships than if imported in American vessels. Furthermore, there was a tonnage tax of 50 cents on foreign and 6 cents on American vessels which gave additional encouragement to the new American merchant marine.

It is a matter of history that this early provision for the protection of shipping and shipbuilding was brilliantly successful—more successful, measured by its actual results, than was the protection simultaneously given to manufacturing and to agriculture. Our tonnage registered for foreign commerce, which was only 123,000 in 1789, had risen to 981,000 in 1810, when we were carrying 90 percent of our own imports and exports in our own ships.

Shipping Our Only Unprotected Industry Since 1861

It is one of the strangest anomalies of legislation that when the Republicans, newly come to power, vigorously reestablished the protective tariff system in 1861 and onward, so far as manufacturing and agriculture were concerned, they did not at the same time extend protection to American shipping. But they did not, though after the war they repeatedly attempted to through various subsidy bills and other expedients. They long found the Democratic party almost solidly opposed to them, together with a faction of Middle Western Republicans, particularly those of German and other foreign descent.

Such protracted Congressional hearings as those before the present joint committee always create an impression that the shipping question is an exceedingly subtle, complex affair. But it is no such thing—as a matter of fact, it is a singularly direct and simple proposition. Ocean shipowning and shipbuilding have not shared the prodigious increase which other American industries have manifested since the Civil War, because ocean shipowning and shipbuilding have been left unprotected—the only unprotected industry of all the range of American industries exposed to foreign competition.

Because of intensive competition, due to the rivalries of maritime governments and peoples, there has actually been more need of protection to the ocean shipping industry than to any other. Yet it has been left on what is virtually a free trade basis. That is to say, except for a few transient mail subsidies to special lines, the American merchant marine in overseas trade has been operating since 1860 without any protection whatsoever, of any kind. There has been no tariff protection and there has been no adequate, sustained subsidy protection that might serve as a substitute.

American People Unwittingly Supporting Foreign Naval Reserves

On the other side, however, among our foreign competitors the ocean shipping industry has been sedulously fostered as has nothing else. Our foreign rivals know well the advantage to them of absolute control of the overseas delivery service of American manufacturers and farmers. They know that the nation which owns the ships has the power to repress American commerce, and that in the long run this is exactly what it will be doing. They know also, these foreigners, that if they can manage to do with their own ships the bulk of our overseas carrying, they are really making us, the American people, support foreign naval reserves that can be turned with deadly force against us in an emergency. This is sufficient to explain the ferocious opposition always offered by various foreign elements in this country to any measure for the upbuilding of a great American merchant marine.

Never before since 1789 have a protective tariff bill and a protective shipping bill been offered together at once for the action of Congress. Never before has it been made so embarrassing for an inland Senator or Representative to vote on one day for a tariff for the encouragement of sheep growing or of wheat growing or of corn growing or of livestock or of dairy products, and then on the next day to vote against a protective shipping bill. It is altogether a very awkward situation for those lawmakers of the interior who have been invoking protection for the benefit of their constituents and have attempted to deny it to the merchant marine.

Opposition of the Agricultural Bloc Broken Up

It is a recognition of this fact that has broken up the anticipated opposition of the agricultural bloc to President Harding's merchant marine bill, on which foreign shipowners and governments were counting with so much exultation. There is a sense of humor as well as a sense of justice among rural as well as among urban Americans.

The basis for protection to the merchant marine is exactly the same as the basis for the protection of manufacturing and agriculture. American wage costs and living standards are higher than those of the Old World. It is this in the last analysis that compels the maintenance of a protective policy in the United States. Our workers expect and need to earn more money to live as Americans should live. Shipowners have to vie with manufacturers and farmers for their workers in the labor markets of our ports and country. It is this hard economic fact far more than the La Follette seamen's law that compels a higher operating cost of American ocean steamers.

A New Form of Customs Tariff

If ocean shipping could be protected by a customs tariff, there is no doubt whatever that American shipping would

have been a well-protected industry in all the years since 1861. But both President Wilson and President Harding have agreed that there are grave reasons of state why the thirty-odd commercial treaties forbidding tariff aid to American ships should not be disturbed by efforts for amendment. Therefore, it has proved absolutely necessary to resort in the present Shipping Bill to a different method of assistance, which, however, is not so different as it may seem to be. As President Harding declared in his address, referring back to the discriminating duties of the Merchant Marine Act of 1920, "The recommendation of today is based wholly on this commendable intent of Congress. The proposed aid of the Government to its merchant marine is to have its chief source in the duties collected on imports. Instead of applying the discriminating duty to the specific cargo, and thus encouraging only the inbound shipment, I propose that we shall collect all import duties, without discrimination as between American and foreign bottoms, and apply the heretofore proposed reduction to create a fund for the Government's aid to our merchant marine. By such a program we shall encourage not alone the carrying of inbound cargoes subject to our tariffs but we shall strengthen American ships in the carrying of that greater inbound tonnage on which no duties are levied, and, more important than these, we shall equip our merchant marine to serve our outbound commerce, which is the measure of our eminence in foreign trade."

It was the original intent of Congress two years ago to aid American shipping by diverting 10 percent of the customs duties to encourage shippers to prefer American ships. President Harding is absolutely right when he urges that there is no essential difference between diverting 10 percent of the customs duties from the Federal treasury and paying out 10 percent of the customs duties for the purpose of direct encouragement of shipping. This is a proposition to which no reply has ever been made because none could be. The cost of either policy is the same to the American nation. Both embody protection to the overseas shipping industry as a whole.

Quibbling Over the Principle of Subsidies Unnecessary

It is full time that there should be an end forever to abstract discussion of the principle or policy of subsidies. There is no discussion of it whatever by any other nation than our own. Other governments and other peoples, if they wish to protect their merchant marine and naval reserve, go about it in straightforward, manly fashion, without sectional or party division. If it is necessary for them to pay a certain sum of money from the public treasury for the maintenance of a national line of steamers to South America or the Orient, they go ahead and do so without quibbling. If it is necessary and advisable to encourage "tramp" steamers by mileage-tonnage subsidies, these other governments and peoples do so, as notably in the case of France and for years in the case of Japan. They see what they want and believe they need, and they go after it with a precision and an honesty that shame the hair-splitting politicians of America.

American Railroads Built Up by Government Aid

What is the use of attempting to deny or hide the fact that most of the American railroads of today were built by the potency of public aid administered at a time when the public could not afford it half so well as it can today? Without that aid the greater part of our magnificent railroad system would still be non-existent. A dozen years ago a rural newspaper of the West aroused much amused comment in Washington. In parallel columns this rural sheet printed two editorial leaders—one passionately championing the grant of a municipal cash payment to aid the building of a railroad line to a neighboring city, the other violently assailing President Roosevelt's recommendation of a subsidy for American ships on the Pacific and to South America. The ship subsidy was denounced as vicious; the railroad subsidy was eulogized as beneficent and holy. Of course they were both essentially the same thing.

In the long line of successive efforts to secure subsidy in this country for American shipping, there has been just one serious scandal—that associated with the postal subsidy to the old Pacific Mail Company a half century ago, in 1872. This is harped upon today by the foes of shipping subsidies—and most notably of all by the foreign foes—as an argument against the granting of shipping subsidies in this year of grace 1922.

Very much less than fifty years ago—perhaps twenty years ago—there was a scandal in connection with the expenditure of public funds for certain harbor improvements in Savannah. But what would be thought of the logic or the sanity of a statesman who should now uprear himself in the halls of Congress and cite that Savannah episode as a cogent argument against the enactment ever thereafter of any and every bill for river and harbor improvements?

Subsidy Opponents Closely Identified with Foreign Steamship Companies

Yet the argument in the one case is worth just as much as it is in the other—and no more. It is an undeniable fact that most of the vociferous talking in America against subsidies to the American merchant marine has always been done by interests more or less closely identified with foreign steamship companies. Just now the lower part of the city of New York—the maritime district of New York—is infested by a great many individuals loudly protesting against any national aid to the American merchant marine—and it is a fact that almost invariably these individuals speak with a pronounced North European accent.

These gentry sometimes adopt other strange and reprehensible methods. The late Senator Gallinger of New Hampshire, than whom no more courteous or honorable gentleman ever lived, was accustomed to find in his mail from time to time letters, always anonymous, denouncing him for his leadership of the movement for American shipping—and all these brave missives bore the postmark of some station in the lower part of New York City, then dominated almost wholly by European steamship offices. Argument by vituperation has, significantly, always characterized both the foreign and domestic enemies of protection to American shipbuilding and navigation. The average anti-ship subsidy editorial alike in New York and on the other side of the Atlantic usually reads as if it were written in the spirit of the common scold.

But it will take something more than these characteristic methods of obstruction this time to check the victorious progress of the present aggressive national movement to bring our ocean shipping interest within the circle of American protected industries. Protection vigorously applied and adhered to has made the United States the greatest manufacturing nation in the world. It has the power—as our foreign rivals know full well—to make the United States the foremost ocean shipping nation.

Noted Mining Engineer Advocates Shipping Bill.—Prompted by many years' study of the subject both at home and abroad, John Hays Hammond, the eminent mining engineer, has wired to Chairman Lasker of the Shipping Board his appreciation of the efforts being made in the behalf of an American merchant marine. "It is regrettable," he said, "that our people do not fully realize the inter-dependence of every class of the community and every section of the Union and that an American merchant marine is indispensable for our export trade upon which the prosperity of all our industries depends."

Ask Your Congressman to Support the Shipping Bill

Hearings Under Way—Endorsement of Congressional Committees Expected—Ultimate Victory Certain But Don't Stop Working Until the President Signs the Bill

By "Old Scotch"

As they say in racetrack parlance, "They're off!" The "they" in this instance doesn't refer to horses but to our solons in Washington. After much preliminary training and several false starts, the long promised hearings on the Administration's subsidy bill, the Magna Charta of American shipping, were begun on April 4.

An auspicious start has been made, inasmuch as the very unusual procedure was adopted, in the case of this measure, of holding joint hearings, that is, the members of the Senate Committee on Commerce and the House Committee on Merchant Marine and Fisheries sit around the same table, thus affording the witnesses the opportunity of addressing both committees at the same time. This will not only save the time of the Shipping Board experts, but it will reduce the time usually taken at hearings of like character by at least half. The chairmen of the respective committees, Senator Jones and Representative Greene, alternate in presiding over the joint committee.

A Bouquet for "Uncle Billy"

Speaking of "presiding," it is a cause of wonderment to see the able way in which that veteran statesman, "Uncle Billy" Greene as he is affectionately known to his colleagues, can wield the gavel and keep things going in a parliamentary manner. Mr. Greene has been in Congress nearly thirty years, and is now 82 years of age. During his long and honorable period of service in the national legislature he has devoted much of his time to problems of the merchant marine, and throughout his entire career has been the staunch friend and supporter of our merchant marine efforts. Both he and Senator Jones can always be relied upon to champion all legislation of a constructive nature, which comes to their committees.

At this writing, the discussion has progressed far enough to see that, barring unforeseen circumstances which may arise, there is a grim determination on the part of the proponents of the bill to give it the favorable endorsement of both committees. In all probability by the time this edition of Marine Engineering and Shipping Age is brought out the bill will be out of committee, and on the calendars of both houses, ready to be taken up for passage. Visitors at the White House have frequently stated in the public press that President Harding considers this measure the most important of all pending legislation, and is using every effort possible to secure favorable action.

Opposition From Our Foreign Rivals

While ultimate victory seems assured, we must "not fool ourselves," a term Chairman Lasker often uses in his testimony, that there will not be much opposition. Our rivals on the ocean are taking a very deep interest in the whole procedure, and view the whole proposition with alarm. Already certain European periodicals are printing lugubrious editorials of the terrible effect the passage of the bill will have on their own shipping, and even going so far as to threaten all kinds of reprisals. They are a very resourceful bunch, and we will have to be on the watch for the working of very subtle propaganda right in our own midst. Evidences of it are already apparent both in Congress and outside in the daily press.

The opposition thus far has centered among several southern congressmen, who are making things lively for the subsidy advocates who have thus far appeared as witnesses. They are no mean antagonists and, while no one doubts their patriotism, it is very hard to follow the reasoning of their antagonism. It is the opposition of other and more subtle influences, fostered by criticising journals, which is the most to be feared.

Facts are stubborn things to overcome and the advocates of the measure are loaded with many which cannot well be controverted. Much will depend upon how these facts are presented as to their ultimate effect on our legislators.

Circumstances Alter Cases

I think it was in an old copy-book that I first saw the maxim "Circumstances alter cases." In any event it is very applicable to the present discussion. While only two years ago, if any of us had even suggested that some of our best cargo vessels in the Government fleet would be offered for \$30 a deadweight ton, he would have been thought crazy. Now, however, where freight rates have been cut to one-quarter of the terms then being offered in a teeming charter market, it is somewhat difficult for a ship that cost around \$200 a ton to even make a living. The prevailing rate of \$30 per ton hardly gives them a chance to compete with similar priced vessels of our rivals, in view not only of the greatly depressed rates but of the scarcity of goods that are moving over the ocean highways.

You can't sell snowshoes in July, nor linen dusters in January: no more can you sell ships when there is no demand for them. But just as surely as the seasons roll around, and make markets for snowshoes and linen dusters, will the conditions change and shipping once more be a going and a profitable business. It is for such conditions that we must make preparations, and the passage of the subsidy bill is the most vital of these necessary steps of preparedness.

Revival of Market for Ship Tonnage Predicted

The Chairman of the Shipping Board stated that, in his opinion, it would take 2½ years before they could dispose of any considerable amount of the Government tonnage, even if this bill passes. I am more optimistic than that, and will predict that with the gradual resumption of business activities now going on, and with the aid of this subsidy measure, there will be many ships disposed of in half that time. We must remember that with only one-third of the Government tonnage in use at the present time, we are carrying less than one-third of our outgoing and incoming ocean business. With the gradually increasing amount of goods to be carried, and the increase of the percentage carried in American bottoms, which must follow the passage of this legislation, there will be a very lively demand for ships.

In anything approaching normalcy in world conditions, Uncle Sam ships out of this country about 45,000,000 long tons of cargoes over salt water, and imports 35,000,000 tons over the same routes. That makes 80,000,000 tons of ocean freights to be carried. If we get only half of our own business, the amount we are aiming at for our own ships, we will have to utilize a great many more cargo vessels than we are now employing. Nor must we forget for a moment the

$250,000,000 of freight money that we will keep in our own jeans.

Antagonism of Labor Pure "Bunk"

Much has already been heard about the antagonism of labor to the subsidy bill. Of all the "bunk" ever listened to which emanated from organized labor, this seems to be the limit. It is simply a question of having a job or no job for real Americans who depend on the sea for a living. It is stretching things very far to have to pick out the clause regarding the proposed naval reserve, with which to find fault. The language objected to is that officers and men who belong to the Merchant Marine Naval Reserve must "obligate themselves to serve in merchant vessels acting as naval auxiliaries in time of war or during the existence of a national emergency declared by the President."

The fear seems to be that "a national emergency" might be construed as a time of a general strike and that the naval reservists might be used as "strike-breakers." Aside from the facts that such a procedure never has been resorted to in this country, and that $3,000,000 per year, the limit fixed by the bill for naval reservists, would not go very far towards manning vessels, it would seem that this idea is the figment of perverted imagination on the part of some leaders.

Opposition Did Not Originate With Engineers

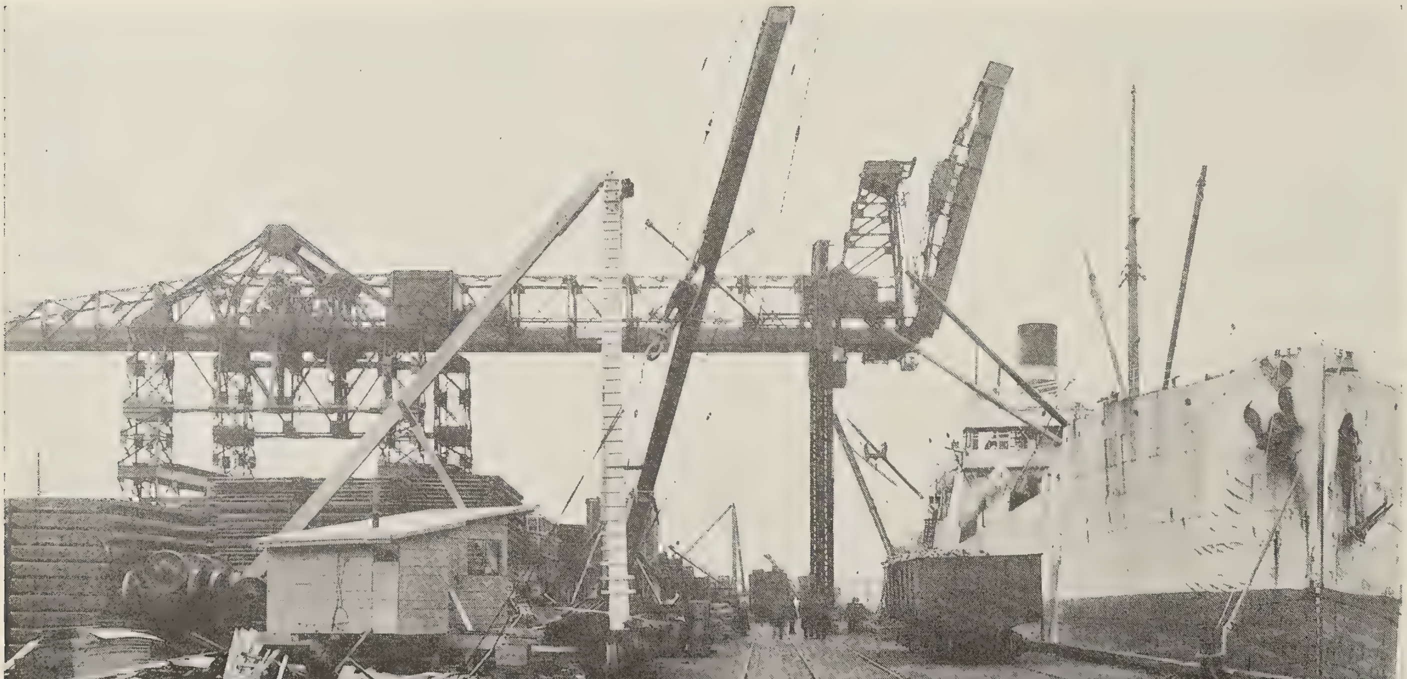
The rights of organized *American* labor on the seas should always be upheld, and, while there is not the shadow of a fact to hang such a suspicion on, as has been advanced, it is quite probable that the proponents of the subsidy bill will be perfectly willing to have the clause "or during the existence of a national emergency declared by the President," eliminated from the bill. To the credit of the engineers' associations, composed as they are entirely of American citizens, it may be stated that the opposition did not originate with them and that they realize in common with all other patriotic Americans that the subsidy bill is the one great effort which promises to give us the much desired merchant marine.

Merchant Marine Association Doing Effective Work

The National Merchant Marine Association, composed as it is of the leading shipowners, builders and operators, and many prominent exporters from all parts of the country, is accomplishing much good work in molding public sentiment in favor of the bill. The Charleston, S. C., Chamber of Commerce has gone on record in favor of the measure, as have also the New Orleans Chamber of Commerce, the Mississippi Valley Association and many other prominent business associations in the South and Middle West, largely through the efforts of the National Merchant Marine Association.

The association has sent out able public speakers, who appear before these commercial bodies and give very cogent reasons why the communities they represent are as greatly interested as are the people who live along the seacoasts. The Shipping Board itself, through the efforts of that splendidly equipped subsidy proponent, Commissioner Edward C. Plummer of Maine, has accomplished much in spreading facts before commercial organizations. Commissioner Plummer has made a lifelong study of this subject and there is no abler man in public life when it comes to discussing American shipping and its needs.

Taking it all together, my maritime brethren, there is no need of apprehension regarding ultimate victory, but do not let this deter you one iota from continuing every effort until the name Warren G. Harding is appended to the bill, thus making it the law of the land.



Gantry Traveling Crane at Seattle Pier

This crane, which covers a section of an open pier at Seattle known as Smiths' Cove Pier A, is of 225 horsepower, electrically driven and is lighted for night loading and operates over a distance of nearly 1,000 feet. It serves the depressed tracks in the center of the pier and also juts out 40 feet over the channel alongside so that cargo can be loaded direct from the car to ship and vice versa. This pier is used almost exclusively for general Oriental merchandise consisting of rice, beans, copra oil, hemp, matting, rubber, camphor and a great many other light commodities shipped from Japan, China and India. On this large pier the chief export cargo handled is steel, lumber, iron and machinery.

Shipping Bill Hearings Develop Exhaustive Testimony

1,500,000 Gross Tons of Passenger, Refrigerator and Fast Cargo Ships Needed to Make Our Merchant Fleet Efficient

JOINT hearings of the Merchant Marine Act of 1922 before the Committee on Commerce of the Senate and the Committee on the Merchant Marine and Fisheries were started in a committee room at the Capitol on Tuesday, April 4, Senator Wesley L. Jones presiding. This shipping bill has the unusual distinction of having been prepared by the Shipping Board, one of whose functions is to advise Congress on such policies as will, in its opinion, aid in the development and establishment of an American merchant marine.

Through the co-operation of the board, assisted by eleven well known marine experts, the President was provided with an elaborate array of facts and findings relating to our merchant marine upon which his recent message to Congress was prepared. In addition to this, a tentative bill was drafted which received the unanimous endorsement of the President and the entire Shipping Board. It was introduced in both houses of Congress in practically identical terms on the same day that the President delivered his message and in order to eliminate procrastination and delay, the Senate and House committees on marine affairs agreed to give it a joint hearing.

In order to expedite the hearings it was decided to allow each witness the privilege of giving his testimony in his own way without interruption, during which the members of the Congressional committees could make notes of the points on which they desired to ask questions. As the bill contains constructive policies of direct and indirect aid covering numerous phases of shipping, ship operation and shipbuilding, the Shipping Board arranged to have its case presented through men who are experts and specialists in their particular line, after which those interested in the proposed legislation and those opposed to it would be given the opportunity to express their views.

Construction Requirements for a Balanced Fleet

"With a reasonable amount of efficiency, we will require approximately 7,500,000 *gross tons of ocean-going vessels to maintain adequate mail and passenger service, to carry the greater portion of our estimated foreign commerce in dry commodities and to maintain our present status in the bulk oil movement.*

"Such a fleet would be composed of approximately 3,600,000 *tons of slow cargo ships;* 1,250,000 *tons of fast cargo ships;* 750,000 *tons of combination liners;* 400,000 *tons of passenger ships and* 1,400,000 *tons of tankers. To achieve a balanced fleet then would involve the construction of* 1,500,000 *gross tons of the higher class freight and passenger ships, in addition to the replacement of old vessels."*
—R. T. Merrill.

Mr. Lasker Gives a General Analysis

"The matter under consideration," said Mr. Lasker, "is not merely one of subsidy or no subsidy; it involves what shall become of the Government's vast war-built merchant fleet; what shall be done to end the large losses of governmental operation of ships through the Emergency Fleet Corporation; what shall be done to insure the overseas carriage of America's surplus products in times of peace; and it involves, in importance possibly beyond all these questions, whether America, through the possession of an adequate merchant marine, shall be self-sustaining, and self-sufficient on the seas in times of war."

He pointed out that times had changed from the pre-war condition of a debtor nation which could be practically assured that the countries that we owed which were maritime nations would furnish us with ships to carry the goods to liquidate our debts to that of a creditor nation holding the first economic place in the world. History proves that no nation that is not strong on the seas was ever able to hold the place that we now occupy.

"We find ourselves today," declared Mr. Lasker, "with the Government owning 1,442 steel ships, aggregating 7,000,000 gross tons, operating 421 of these ships at an estimated cost to the Treasury for the comming year of $50,000,000 and with 1,021 ships tied up; we find private operations, as well, being conducted at startling losses due not only to depressed world conditions but to the impossibility of the private owner maintaining himself in the face of continued Government competition."

He explained that the purpose of Government operation, as defined by law, was to build up trade routes in order that the Government ships might thus be sold with established good will to private owners. The very method chosen has worked to defeat its own purpose, for, in the upbuilding of those routes, the Government has operated ships; and, in the operation of ships, has driven its potential customers largely off the seas. Thus, we come to conclusions —from which there can be no escape—that, since continued Government operation means finally the possible and likely elimination of private operation of American ships, a method must be devised whereby the Government shall end its operation and, at the same time, insure carriage of American goods under the American flag through private ownership as contemplated by the Jones Act.

"Europe owes us governmentally and privately some fifteen billions of dollars," he said. "To pay in gold is impossible; there is not that much gold in the world. The only way that Europe can pay will be in goods, either raw materials or manufactured or partly manufactured wares. In turn, we must find new markets not only to absorb the surplus products, which Europe formerly took from us, but to provide for the sale of many of the products which Europe shall send to us in settlement of her debt. These products, if in raw or partly manufactured state, will be brought to completed processes by American labor; but, if permitted to flood our own market and if we do not find a foreign sale for them, they will so depress the price of wares at home as to threaten the prosperity of all our workers.

Farmers Demanding Marine Developments

"These newer markets lie across the ocean: to the south in the Western Hemisphere; to the east, in China and Siberia. It is the very need of trade in these markets that is the inspiration of the policy of the open door in the Far East."

"The farmer," declared Mr. Lasker, "has but recently seen

what it means to him in depression in price of his entire production when exports fail and the surplus of this production backs up at home. We have but lately seen how our Government's expenditure of $20,000,000 plus $12,000,000 from the Soviet Government, for grains to starving Russia, marked the beginning of an uprise in price of all our cereal products From the very time that these purchases began the price of wheat, corn and oats rose. It is not contended that these purchases alone were responsible for the uprise, but they were one of the several factors that resulted in the farmers' depression being alleviated.

"The farmers of our chief 18 agricultural States," he said, "with a total population of 40,000,000, are making a demand to which an affirmative response seems certain—that the ocean be brought nearer to them by the building of the St. Lawrence waterway, a conception that our Middle States will refuse to surrender until it becomes a reality. There can be no certainty of even a fair trial of that project after it is built unless we can have a profitable operation of American ships, because the carriage in that waterway is but seasonable, and other nations might not afford to work out a system of flexibility of tonnage for use in that waterway to our advantage. Assured flexibility for use of that project must come from us and from us alone. Therefore, when the farmer's dream of the St. Lawrence waterway comes true, as come true it will, it can have no assured life without an American merchant marine, and that merchant marine should be well established before the canal becomes a reality, that companies of sufficient strength may be alive to take advantage of its opening.

The Naval Auxiliary

"Having agreed to a naval program of 5-5-3 we can have no thought or hope of actual naval equality unless we can supply and bunker our Navy through our own merchant ships in time of war, should that unhappily come again. When President Roosevelt sent our Navy around the world, it had to be supplied and bunkered by foreign flag ships. Our naval jaunt showed the nations of the world its feet of clay. In 1914, when the world war began, be it said to the shame of America, she possessed but 15 passenger ships as to be of use for naval auxiliaries, while Great Britain possessed over 200 such ships. Today we possess 50 to Great Britain's 250. But when age and speed, which are the determining factors in the use of such ships for naval purposes, are considered, Great Britain's margin over us is further increased."

American Ships Making Poor Showing

"During December, foreign ships carried 76 percent of our overseas general cargoes," said Mr. Lasker, "and 24 percent was left to be carried in American ships. This 24 percent measured our success in competing against foreign nations for the carriage of our products to the markets of the world. Of the 24 percent, 19 percent was carried in Shipping Board vessels and 5 percent by private American owners.

"It must be the purpose and aim of America, and the Shipping Board emphasizes its belief that this aim can be accomplished, to carry at least 50 percent of our foreign trade, other than with contiguous countries and nearby countries under the American flag, privately operated. We are today carrying 87 percent of our oil trade with Mexico and 57 percent of our Caribbean trade in our own ships. But neither the needs of the trade with Mexico or the Caribbean call for that type of ship which is the very backbone of the second line of defense of our Navy, nor the type of ship which is the forerunner of world trade and world intercourse—the fast passenger and the combination passenger and cargo ship.

"There are many things necessary to successful ship operation in which the Government cannot engage. For instance, often it becomes necessary to buy and sell merchandise in order to insure cargoes. The most successful fleets under the American flag are those of the United Fruit Company, the United States Steel Corporation, the Bethlehem Steel Corporation and the Standard and other oil companies. The owners of these fleets are engaged in trading and thus insure full tonnage. No Government operation can do this. The Shipping Board at the present time is negotiating for the sale of several ships to a concern, which in turn is negotiating with the Chilean Government, whereby the American concern sells the Chilean Government 300,000 to 600,000 tons of coal a year for a term of years, during which time it takes 300,000 to 600,000 tons of nitrate in exchange. Thus those ships are assured of cargo through trading connections.

Government Aid Necessary

"Private ships under the American flag must be governmentally aided, because of the higher standards of living of American labor in the shipyard and on the ship. The men who build ships, work in America with a higher wage; the men who man our ships are paid more and sustained better than the foreigners. Who in America would have it different? Who in America would question that the prosperity of one should be the common prosperity of all and that these higher standards should prevail with all the people of our country? It is of prime importance, if we are to have an American merchant marine, that our merchant marine should consist of ships built by American workmen in American yards, because, if we are once again engaged in war, unless we control our own yards and our shipbuilding, we will be lacking in the means of instant and sure repair and renewal."

Government Aid Absolutely Essential

"With the experience I have had in this and other trades, I want to say that any man who claims that without a subsidy and without the kindly support of the Government he can build up permanently an American service of combination cargo and passenger ships, on competitive routes, and particularly on the Pacific, where they are most urgently needed for protective purposes, is either badly advised or, for reasons of his own, is making statements which are not so."—A. J. Frey, vice-president, in charge of operation, Emergency Fleet Corporation.

Statement of Mr. Daniel H. Cox

Mr. Cox, of the firm of Cox & Stevens, New York, prominent naval architects, pointed out that "it is obvious that the merchant marine of any country desirous of competing successfully with other countries in commerce on the high seas must be composed of ships which individually are equally as efficient as those ships of other nations engaged in the same trade." Particularly is this true of such a nation as the United States, he declared, "which labors under definite natural handicaps as compared with other nations already well entrenched in the carrying trade of the world.

"If to the unavoidable disadvantages, such as higher cost of construction with accompanying higher charges for interest on investment, depreciation and insurance, higher cost of wages and subsistence of officers and crew, lack of established connections in the various seaports of the world, and the nautral difficulty of securing business that for many years has been handled by other countries, be added to the handicap of ships not suited for the trade in which they are employed, the case is hopeless.

"Only by the use of the most efficient type of ships can we, even with the most liberal form of Government assistance, render the regular and reliable service demanded, at the going rate, and hope to make the venture a profitable one."

Mr. Cox stated that from a general knowledge of the shipping situation, it is his belief that the American merchant marine is seriously lacking in ships of the following characteristics:

(1) Passenger and mail ships of 15,000 gross tons and up, with speeds of 18 knots and over.
(2) Passenger and cargo ships of 10,000 to 15,000 gross tons with speeds of 14 to 16 knots.
(3) Fast cargo ships of 9,000 deadweight tons and up, with speeds of 12 knots and over.
(4) Refrigerator ships of 8,000 to 12,000 gross tons, with speeds of 14 to 15 knots.
(5) Ships propelled by Diesel engines or Diesel electric drive.

Homer L. Ferguson Testifies

Whether or not our legislators, now that there is no immediate danger of war, will be influenced by the importance of the merchant marine as a naval auxiliary, there is no doubt in the minds of thinking men that this is one of the most important reasons for developing our shipping. Mr. Ferguson said in part:

"As the number of war vessels is to be restricted, the importance of the merchant fleet as an auxiliary to the war fleet is correspondingly enhanced. Should war fleets be abolished altogether, the sea would be definitely in control of those powers having the largest and best equipped merchant fleets. Heretofore the American naval fleet had existed without a corresponding merchant fleet, which has generally been held as necessary to a strong Navy. Great Britain and the United States agree that their naval fleets should equal each other in strength; it does not, however, follow that their war strength on the sea will be equal, because that country having the best shipping inevitably would have a tremendous advantage. A merchant fleet is always a potential war fleet and forms, both in equipment and men, a naval reserve, whether called that or not. To neglect merchant shipping while limiting war shipping is deliberately to invite disaster. Many great issues have been decided by merchant shipping in the absence of suitable naval vessels. The British fleet of 197 vessels, of which only 34 were naval, destroyed the Spanish Armada, a blow from which the maritime power of Spain has never recovered.

"American shipbuilding up to the war had been built primarily on the demands of the Navy, and nearly all of the large shipyards had been developed mainly with the idea of satisfying those demands. While merchant shipbuilding has been important, the types and character of the merchant ships built in this country have not been at all in keeping with the best vessels built abroad, so that it has only been in our warship construction that we have kept pace with the shipbuilding art in regard to engineering features, size, power, speed and shipyard equipment both in men and tools.

"With large naval building definitely abandoned for at least 10 years, it stands to reason that the large, well-equipped shipyards must build large and powerful merchant ships, or the ability to produce, either for a merchant marine or a Navy, will become very much weakened and probably disappear. There is no engineering feat requiring more training and ability than the building of large, powerful vessels. If the number of large cruisers is limited or if they are abandoned altogether, armed merchant vessels will be quite as useful then as large cruisers are now in case of war."

Passenger Ships and Immigration

A great deal has been printed about the ruinous freight rates that shipowners have been compelled to accept for the carriage of cargo but very little prominence has been given to the fact that passenger fares are still practically at their maximum. Passenger ships in the transatlantic trade that are modern and efficient are making good money. It is this type of vessels that are badly needed to balance our fleet and it is this type of vessels that capital could be most easily obtained for, if the Government sees fit to grant sufficient aid to equalize the difference in first cost and operation between American and foreign ships.

Mr. Rossbottom, general manager of the United States Lines, testified that "the foreign steamship organizations that have been operating steamship lines of foreign registry between Europe and the United States have expended millions of dollars in their respective countries for the construction of new steamships, and have paid large dividends to their stockholders as a result of engaging in a passenger and freight traffic that either originated in the United States or was destined to the United States.

"They have not found it very difficult to convince the citizens of their respective countries that when traveling to and from the United States on pleasure, or on business, they should patronize the steamship flying the flag of the country of which they are natives. This applies equally to English, French, German, Italian, Japanese, Norwegian and other European nationalities. Neither has it seemed difficult for these foreign steamship lines to induce American citizens, whether traveling officially or on pleasure or on business, to patronize steamships of foreign registry even in preference to steamships of American registry, and, as Americans form the large majority of travelers in the first and second cabins, we have seen the rapid development of the merchant marines of all foreign countries through money earned in this country.

"There is, however, one part of the passenger traffic to the United States that Congress can assist in diverting to steamships of American registry, and thereby furnish the nucleus of an earning capacity that will place American steamships in a better position than ever before to compete with foreign steamship lines for the traffic to the United States, and that is by favorably considering the suggestion that has been made, that not more than 50 percent of the alien passengers arriving in the United States shall be brought here in foreign vessels."

Time Opportune for Building Up Our Merchant Marine

"This is the time to start the upbuilding of our merchant marine. The foreign lines have been hit just as well as we have, and while they have not abandoned a single essential route or service that they covered prior to 1914, *they are reducing their tonnage in keeping with reduced revenue and volume of cargo moving. If we can establish our services, therefore, under existing conditions, we will surely prosper as these conditions improve, for it will give us an opportunity of proving to merchants that we are in the business to stay, and thus will gain their good will and their support when world trade improves. This, however, cannot be done unless the Government comes to the aid of the merchant marine for reasons previously set forth."*—W. J. Love, vice-president, Emergency Fleet Corporation.

Developments in Marine Insurance

Liner Rates for Shipping Board Boats—"Leviathan's" Insurance—Floating Mines—Lake Navigation—Pilferage

By "Bordereaux"

IT has been a distinct achievement to secure such fine co-operation between marine underwriters and the Shipping Board authorities as to gain the significant concession of first class liner ratings for the best grade Board vessels. This places the latter on a parity with similar tonnage with which they have to compete in foreign carriage, and will attract a substantial volume of shipments to American vessels—thus greatly benefiting both shipper and shipowner. One authority has estimated that the saving in insurance cost to shippers will vary between five and twenty-five cents per hundred dollars carried.

In this department last month an account was given of the organization of a determined effort to work out a classification of Shipping Board vessels for insurance rating purposes, through committee conferences representative of the Board and of leading marine insurance interests. Sooner than could have been hoped for by the most sanguine have come the fine results alluded to above. They represent mutual concessions—a willingness on the underwriters' part to stretch a point wherever they could, and on that of the Board to correct the minor structural defects in their vessels objected to by the former. For an initial step in the proposed series of agreements it is a decidedly important one. The first class ratings are applicable to vessels of the Shipping Board under twenty years of age, as also the 535- and 522-foot types for both passenger and cargo service, and the former German liners now under the American flag in the Atlantic trade. They affect such lines as the Munson, United States, Admiral and Pacific Mail, operating to South American, Far Eastern and European points.

The classification conferees are now at work on Shipping Board vessels of the next grade of importance, and in order thoroughly to understand their capabilities in this respect the underwriters are studying their voyage accounts to learn of their behavior at sea, the ability of their officers and crews, their engine capacity, etc. These out of the way, the smaller freighters are to come up for consideration.

In the conferences to date the underwriters have been represented by Charles R. Page, Hendon Chubb and William H. McGee, and the Shipping Board by Vice-President William J. Love of the Emergency Fleet Corporation, Commander R. D. Gatewood and B. K. Ogden.

Insuring the Leviathan

WIDESPREAD commendation is very properly being accorded American underwriters for the admirable support they gave the Government in the insurance of the *Leviathan* on her run to the Newport News yards where she is to be reconditioned for service in the Atlantic passenger trade. The brokers whom the Government called in to handle the placing of the insurance are loud in praise of the fine spirit displayed by our underwriters in drawing the bow to its full American capacity. While it is true that our market was exhausted before half of the required coverage had been effected, and that as much more had to be placed elsewhere, the fact remains that American marine insurance did its best, and in so doing eclipsed any previous performance of the kind in this country. Incidentally, the "get together" spirit manifested demonstrated the effectiveness of the American Marine Insurance Syndicates; only one office outside of the syndicate membership participated in the insurance.

The eighty odd companies in the syndicates accepted $2,000,000 for the trip to Newport News at a rate of one-quarter percent and on a valuation of not less than $4,000,000. The other office took $200,000 additional. This left $2,000,000 to be placed abroad. On betterments at the yards, covering on labor and materials and certain incidental expense, a builder's risk insurance was taken out by the Government for a total of $6,551,000. This attached from the time the vessel reached the yards until the reconditioning has been finished—a period of between twelve and fourteen months, it is estimated. The Government assumes the risk on the vessel itself. Of this builder's risk coverage the syndicates accepted $2,500,000, and the balance was placed elsewhere. The valuation was fixed at not less than $4,000,000.

Floating Mines Still Being Found

IT may have been a considerable time since the late world war ended, but war risk insurance is still desirable. The Hydrographic Office of the Navy Department recently sent out a radio broadcast announcing that a floating mine had been sighted directly in the pathway charted for lines plying between Boston and Europe. The exact location was given as south of the Grand Banks and west of the junction at sea where vessels bound from Europe for Boston leave the track of the Europe-New York liners and bear almost due west. Since the first of last year eight floating mines have been located in the North Atlantic off the American coast, and two off our coast to the south.

Lake Navigation Opens

THERE is a general feeling of optimism among underwriters with respect to the outlook for a better season than last in insurance operations on the Great Lakes. Ice conditions were favorable in the neighborhood of the upper ports considerably earlier than the official date of the opening of navigation, which is April 15, and there was an occasional sailing around the first of the month. The former valuation of $70 per ton will probably prevail this season, and the rates will be little altered despite the complaint of the underwriters that they should be and that the margin of profit is always too near the vanishing point for comfort. It is anticipated that the strike of the coal miners will have the effect of eventually reducing the output of the mines that ship from the lower ports. This would mean that the freighters that carry full cargoes of ore from Lake Superior would have to return light, as coal is regularly their principal cargo on the voyages north.

A Significant Straw

THAT a revival of foreign trade and a consequent increase in ocean marine insurance operations is due in the near future is the significance attached to the entry into that field of the powerful group of companies composed of the North British and Mercantile, Pennsylvania Fire, Commonwealth of New York, and Mercantile of America. This

important step has more than over-balanced the regret so generally expressed on account of the recent retirement of the Ætna Insurance Company from ocean marine. It is felt that such astute underwriters as those in control of the North British group would not have made this move had they not weighed every probability in advance and concluded that the worst is over and that better times for marine insurance are scheduled for an early appearance. Excellent judgment was also exercised in the selection of a marine insurance manager, their choice falling upon the veteran Albert Ullmann, who has been one of the most highly regarded underwriters in the New York market for the past twenty years.

Foreign Manager Appointed

STILL another indication of faith in our foreign trade campaign is conveyed by the action of the American Foreign Insurance Association in selecting John Ferguson, until recently manager of the Union Marine Insurance Company of Liverpool, as marine manager. Mr. Ferguson brings to his new and important duties an experience of twenty-six years as a marine insurance expert at Liverpool, Manchester and New York. He has been in command of a group of 250 agencies throughout the world, as their supervisor, and is eminently equipped to handle the many intricate problems involved in securing to American underwriters their proper share of coverage on world trade. As rapidly as circumstances justify it he will establish general headquarters in the various countries and through them sub-agencies at numerous important local points. There is general satisfaction in the selection of so capable a manager, and underwriters are looking forward to an increased revenue from remote geographical areas in consequence of the steady expansion of the American Foreign Insurance Association.

Favor Use of Spuyten Duyvil

UNDERWRITERS on inland marine risks are urging the adoption of the proposed plan of purchasing sufficient property at Spuyten Duyvil to enable the Harlem River to be widened and deepened so as to permit modern canal barges destined from North River points to East River points to make the trip through the river instead of proceeding as at present around the Battery, a distance of some twenty-eight miles.

Organized Pilferage

REPORTS from authoritative sources continue to accumulate evidence in substantiation of the belief that pilferage on the North Atlantic has reached a stage of scientific organization. It is now next to impossible to determine whether these depredations have occurred on board ship or not, and this is a matter of the utmost moment to the shipowner. Substitution of worthless junk for the original contents of the cases has reached a degree of perfection that elicits something akin to admiration. Most of it is believed to be done on trains or on lighters, and it is being urged that more extensive use be made of the numerous effective safety devices that have recently been introduced for the greater security of packing.

Collision a Marine Risk

JUDGE HOUGH recently decided, in the United States District Court, Southern District of New York, that a collision between vessels sailing in convoy and without lights was the consequence of a marine, not a war, risk. The court refused to consider the nature of the cargo as relevant, insisting that it was the nature of the operation which was the determining question. Negligence on the part of the navigators was maintained as the proximate cause of the collision. The underwriters were held liable for the loss. Such a court decision may come in handy in event of outstanding war risk claims coming up for settlement by shipowners.

Freight Claims

IT is frequently asked whether claims may be successfully pressed on account of freight which has been unearned by reason of the loss of a vessel, or for non-delivery or short delivery of merchandise. No accurate general answer can be given, but it is suggested that when the freight unearned can be accurately computed the amount thereof be added to the bill against the carrier. It may or may not be honored. There is usually a provision inserted in the contract of affreightment whereby the freight accrues to the shipowner's vessel "lost or not lost." It might be possible, if the amount involved were sufficiently large to justify suit, to collect the amount of freight that has been paid but unearned because of failure to deliver the merchandise. In the main, however, it is too small a matter to take much bother over.

Oil in Harbor Waters

INDISPUTABLY there is much room for improvement as regards the pollution of harbor waters through the discharge of waste and fuel oil, but even so, matters are on the mend. The National Fire Protection Association recently came out with a circular calling attention to unsatisfactory conditions in this respect at certain locations, notably Beard's Erie Basin, Atlantic Basin and the mouth of the Gowanus Canal, Brooklyn. It finds a general slight improvement of late and accounts for it on account of the co-operation of the shipping industry, which the Supervisor of New York Harbor has secured by the formation of a special committee. The activity of the United States Attorney's office in connection with specific violations of the law is also believed to have helped the situation. Better facilities are gradually being afforded for the removal of oil from ships, making it more convenient to dispose of it than to throw it on the water. National legislation, intended to improve conditions not only with respect to New York and other harbors, but also in behalf of the preservation of fish and bird life, as well as the beach resorts, is before Congress.

Inferior Ships

CHEAP freight rates are attracting shipments from South America to the United States in steamers of decidedly inferior class, not to mention lighters in tow, and sailing ships. This is giving the underwriters considerable concern. They cannot understand why merchants should be willing to take such serious chances with their cargoes, particularly as there is no occasion for so doing in view of the repletion of idle but standard steamers. A large amount of sail tonnage is now being operated in the North Atlantic and West Indies trade, and wool cargoes are going under sail from London to so remote a point as Australia. It should be borne in mind that many underwriters do not insure sailing ships at all, and merchants employing that form of transportation are likely to find themselves embarrassed when it comes to effecting coverage under open or closed policies. It is much better all around to make use of safe bottoms.

No German Insurers Coming

ABOUT so often a rumor gets whispered around to the effect that German underwriters are planning to resume operations in the United States. There is nothing to it. Financially it would be impossible for German unadmitted marine writing companies to establish them-

selves here; the low rating of the mark on exchange would effectually dispose of any such undertaking. The Germans themselves are without information as to a probable date of release of funds of German companies that were operating in New York prior to the war and whose American resources now rest with the alien property custodian. Congress will have to settle that. Liquidation of claims against German companies on policies in force before our Government seized the branch offices has been completed, but the remaining assets have not been released and nobody knows when they will be.

Some London Recommendations

IN the interesting report of the Committee of the Council of the British Chamber of Shipping, recently published, an almost despairing review is made of the wholesale amount of pilferage still being carried on in all parts of the world. The committee conducted a world-wide investigation of the subject in order to try and arrive at adequate remedial measures. It found a general paucity of police protection and severely arraigned the carriers for alleged laxness in safeguarding shipments while on docks and during actual loading through failing to provide adequate watchmen service and by failing to insist upon the arrest of dockhands suspected of stealing. Among the recommendations made by the committee were the following: Tallies should be taken both in and out of ship, and extended use should be made of the alphabetical system by those tallying on behalf of the ship, as it prevents collusion with those using continuous sheets tallying against the ship; there should be only one entrance to cargo holds (down the hatchway); all ventilators should be protected to prevent access to holds through them; shipowners should prosecute every detected case of pilferage; magistrates should be urged to impose imprisonment on persons convicted, as fines are inadequate; customs officials should mark with an official stamp or seal all cases or casks from which samples have been extracted; and shipowners should revise their standing instructions to masters and officers in reference to the care and handling of cargo, to bring them up to date.

Maritime Nations Propose International Regulation of Deck Loads

THE proposal of foreign maritime powers for the limitation or total prohibition of deck cargoes, and the establishment of an international load line, is of the greatest importance to American shipping.

According to dispatches received from Geneva, Switzerland, by Ernest Greenwood, American correspondent of the International Labor Office, representatives of foreign governments, shipowners and seamen on the Joint Maritime Commission of the International Labor Organization, are in unanimous agreement as to the need of international action in the matter. Whether this action will take the form of regulations based on the present British rules, as is desired by the seamen, or whether modified regulations will be adopted, as the shipowners prefer, remains to be settled. It is said that a radical divergence of opinion also exists among the delegates as to whether regulations should authorize specific rules restricting the height and weight of deck cargoes, or whether they should permit the certification of vessels as fit for the carriage of deck cargoes, according to type, and with or without a special load line.

It is contended by the seamen's organizations that many lives have been lost and many men injured at sea each year by the carriage of deck cargoes. It is the hope of the seamen to have the British regulations used as a basis in the adoption of international regulations. On the other hand the opinion seems to prevail among shipowners and shippers that the British regulations are too stringent and that elasticity might usefully be introduced into the rules. The shippers point out certain anomalies arising out of the strict application of the British rules, and mention two specific cases, one the case of a turret-deck ship; the second case was that of a ship being penalized at Hamburg for being insufficiently loaded, owing to her having rejected a deck cargo in America, because of the penalties she would incur in Great Britain for overloading.

This is the first time the question has been discussed by both shipowners and seamen. It has long been a matter for discussion among shipowners, conferences having been held at Paris in May, 1921; at Madrid in October, 1913, and at the Hague in August, 1921. The seamen themselves have gone into the matter at meetings at Washington and Antwerp.

The present joint conference is made possible by the establishment of the Joint Maritime Commission by the International Labor Organization, an autonomous association of 54 nations established under the Peace Treaty of Versailles. The present negotiations involve Belgium, Japan, Great Britain, Sweden, Canada, France, Italy, Norway and Germany, these countries being represented on this commission.

Steam Versus Diesel Drive

By J. E. P. Grant*

FOR long voyages there is no doubt but what the Diesel engine has arrived and will do more than any other single factor to reduce the cost of operation.

The selection between steam and Diesel drive depends almost entirely on the respective initial costs of these installations. Diesel engine prices in the United States are very high yet, and this, of course, decreases the range of desirability of this type of engine.

Where to draw the line between steam and Diesel drive requires special study of the particular trade in view, but generally speaking, I would say that for powers up to 4,500 indicated horsepower and for voyages of four thousand miles and over, the Diesel engine is preferable, and that for powers above that mentioned and below the four thousand miles, steam should be selected. The minimum distance of voyage mentioned above will decrease as the costs of Diesel engines come down.

New Southern Pacific Oakland Piers

By Charles W. Geiger

THE Southern Pacific Railroad has recently completed at the Oakland, Cal., mole three new piers with berthing capacity for twenty-four vessels. More of these piers can be constructed as needed. The new piers are located on the south side of the mole. The present facilities consist of three units, or piers, which are located at an angle with the bulkhead line and are respectively 100 feet, 70 feet and 75 feet wide and each 875 feet long. On pier No. 1 is located a warehouse 80 by 380 feet in size with a floor space of 30,000 square feet. The trestles are full-span so that there are no posts to interfere with the handling of loads in the warehouse. This shed is served by two tracks down the center so that cargoes may be wheeled directly from slings to cars. The entire side is made of sliding doors so that any portion can be reached conveniently. Night loading is facilitated by excellent lighting arrangement.

Fifty vessels a month, carrying lumber, are unloaded at these piers. Trucks are so arranged on the lumber piers that transfer may be made direct from boat to cars. The facility with which lumber may be handled here is illustrated by the fact that one boat unloaded 155,000 feet of lumber in two hours.

*Chief engineer, Merchant Shipbuilding Corporation, Chester, Pa.

Shipping and Shipbuilding in Great Britain

Cargo Boat Owners in Financial Difficulties—Liner Companies Appeal for More Capital—Shipbuilding Situation Chaotic

By W. H. Wendon

THE effects of the great depression in the shipping trade of the world are becoming increasingly evident in the financial affairs of British shipowning companies, notably in South Wales, where "mushroom" owners were to the fore in promoting companies during the late boom. The balance-sheets of some of these cargo boat companies covering the past year's working are now available, and it is the exception to the rule for a satisfactory result to be shown.

Failure of Cargo Boat Companies

The latest concern to announce its inability to continue trading is the Turner Steam Navigation Company, Ltd., which was formed early in 1920, with a nominal capital of £100,000, of which about £40,000 has been subscribed. The directors contribute the failure of the company to "the serious depression in shipping values, which set in a few months after this company was formed," and add that it has been found impossible to meet the heavy obligations of the company and carry on the business profitably. No less than £30,000 is due to mortgagees on the company's solitary steamer *Torquay*, of 1,054 tons deadweight, built in 1914. The mortgagees have served formal notice calling in the money forthwith. The vessel cost the company the appreciable sum of £74,000 in March, 1920, when the company was originally formed by its then promoters, but her market value at the present time is estimated to be between £15,000 and £16,000. There appears, therefore, no other course to adopt but to voluntarily wind up the company, and the necessary resolutions to effect this policy will be submitted to the shareholders.

The Bristol Channel Steamers, Ltd., is another Cardiff cargo boat concern which finds itself in difficulties. The depreciation in shipping values has impelled the directors of this company to counsel the reduction of the capital by fifty percent, representing approximately the present day value of the assets. This company provides one of the instances where, a large portion of the purchase price of the vessels not being borrowed on mortgage, the company can continue running, at all events for the time being.

The Heath Shipping Company, owning the small steamer *Deloraine*, sustained a loss of £668 on its past year's working. Added to the debit balance of £248 brought into the account, there is a total loss in the past two years of £916. The share capital issued amounts to £13,674, and there is an overdraft at the bank of £10,026. The company's steamer and leasehold buildings cost £22,250. Comment is needless.

Largest Cargo Boat Owners Fail to Declare Dividends

The St. Just Steamship Company, probably the largest purely cargo boat company in this country now that the ill-fated Western Counties Company is no more, is also experiencing troublous times, although not to the same extent as others. Partially owing to the slump, and to some extent to the fact that the company's taxation indebtedness has not yet been fully defined, the directors are refraining from recommending the customary dividend. The magnitude of the activities of this company, which is an amalgamation of single ship companies, will be gaged from the fact that it owns 21 steamers aggregating more than 180,000 tons carrying capacity, and standing in the company's books, together with investments, at two and three quarter millions sterling. It has, indeed, more money invested in shipping than any other cargo boat company in the kingdom. For the fifteen months ending June 30 last a dividend of 6¼ percent, free of tax, was paid, as against 7½ percent in 1919-20, 17½ percent in 1918-19, 10 percent in 1917-18, 20 percent in 1916-17 and 21 percent in 1915-16. It has a capital exceeding £2,000,000.

Turning from cargo boats to liners, the position regarding companies owning this type of vessel is rather more obscure. On the surface the companies are not doing badly; but appearances are sometimes deceptive. There is no disguising the fact that at all events some of the companies are in an unfortunate position following on the slump in values, for many of them have disbursed gigantic sums in acquiring boats at top prices to replace vessels lost during the war.

Liner Owners Ask for More Capital

Appeals for further capital continue to be a feature in the liner trade. Since the beginning of 1921 these appeals have aggregated no less than £14,500,000, and there are more to come. The Cunard Company initiated the movement in January last year, when it applied for, and obtained with consummate ease, £4,000,000. Then followed the African Steamship Company, the Clan Line of Steamers and the Union-Castle Line, and finally we have the P. and O. Company securing a further £3,500,000 and Messrs. Lamport and Holt £2,000,000.

In the case of the P. and O. issue, the money, according to the prospectus, is to be applied "more especially to the construction of new vessels when prices come down to an economic figure to replace those destroyed by enemy action during the war, and to build others to meet the growing requirements of the company's business." But it is significant that, in the case of the other companies, the money will be expended in meeting the payments on steamers already built at top prices, or which have been contracted for on a similarly ruinous basis.

Prospects for the Future in Shipping

Opinions differ as to the stability of the industry and the prospects for the future, but at least one shipowner, Sir William Noble, Bart., whose authority to speak on matters maritime cannot be questioned, is not disposed to indulge in pessimism. He goes so far as to say that the shipping industry is now approaching convalescence, if, indeed, it is not wholly on the road to recovery. He prescribes a sane and reasonable optimism as one of the best aids to this recovery, and expresses the view that a cynical pessimism can only prolong the period of distress. He points to the fact that in other countries the condition of the industry has been just as bad, if not worse, and deprecates the use of what he terms "quack remedies." He pleads guilty to being an incorrigible optimist and declares his admiration for the pessimist who has the courage, when the soup kitchens are open, to order half-a-dozen steamers. For his own part he prefers the philosophy of the typical Irishman, who, when difficulties confronted him, said: "Let me look back into the future."

According to the latest statistics, there are more than 2,000,000 tons of British and foreign shipping at present laid up in the 36 principal ports of the United Kingdom, a figure which compares with one and a half million tons in January last year. Of the two million tons referred to,

no less than 1,900,000 tons fly the British flag. The subjoined table gives particulars of unemployed seagoing ships laid up in these 36 United Kingdom ports since the beginning of 1921:

		British		Foreign	Totals
1921	No.	Gross tons	No.	Gross tons	Gross tons
January ...	...	....	...	....	1,505,000
April	...	....	...	....	2,732,000
July 25.....	883	2,641,000	140	323,000	2,964,000
October 25.	654	1,853,000	88	221,000	2,074,000
1922					
January 1..	621	1,887,000	91	205,000	2,092,000

Taking the smaller ports into consideration, it is calculated that at present there are vessels representing two and a quarter million tons laid up in the ports of the United Kingdom. With regard to British tonnage only, no account has been taken in these figures of ships lying in foreign ports. Careful computation places the total figures of unemployed British ships at 2,250,000 tons, out of a gross tonnage of over 18,000,000 tons, or 12½ percent. High as this proportion is, the figure does not compare unfavorably with foreign countries.

Regulations for Carriage of Wood Deck Cargoes

The important question of the regulations regarding the carriage of wood deck cargoes, which have been the subject of considerable discussion during the last ten years by various sections of the interests concerned, has reached a still more interesting stage. The Chamber of Shipping of the United Kingdom has addressed a communication to the Board of Trade, setting forth the views of the International Deck Cargoes Committee, which was one of the committees appointed by the International Shipping Conference held in London last November. In submitting the proposed regulations for the consideration of the Board of Trade, the Chamber of Shipping draws attention to the different practices of various countries in the definition of "winter seasons in Northern Europe and in the Northern Atlantic," which, as is pointed out, for the ordinary cargo freeboard regulations, are different from the present British regulations regarding the carriage of wood deck cargoes. The Chamber considers that the Governments of various countries should take common action to define the winter season, not only for the North Atlantic, but also for other regions of the globe, so that as far as possible fair treatment may be given for the seasonal variations of freeboard which all systems of rules take into account. The Chamber observes that this is the first time that it has been possible to secure unanimous agreement as to such technical regulations among all the countries in Northern Europe primarily concerned in the carriage of deck cargoes, and that the acceptance of rules of this nature will not only facilitate the free intercourse of merchant ships of all nationalities, but will appreciably reduce the cost of transportation of light wood timber to the British Isles—an important point in the general economy of the country.

The committee recommends that:

(1) All ships should have a certificate of fitness where the deck cargo exceeds 5 percent of the ordinary deadweight capacity;

(2) The various maritime States should agree on a uniform system of issuing such certificates;

(3) International expert opinion should be asked to decide whether, in addition to the above requirement, a uniform system of fixing a special load line and regulations restricting height and weight of deck cargoes would be desirable.

Shipbuilding Hard Hit by Taxation and Wages

The situation in the shipbuilding and engineering industries is by no means an encouraging one. Labor disputes on wages and the exercise of managerial functions have brought the trades to something amounting to chaos. Added to this, such few orders as are being given out are finding their way abroad, whereas in the normal sequence of events they would undoubtedly be booked up by firms in this country. A Hartlepool firm which tendered for five passenger ships for a Mexican navigation company is advised by the shipping company that England is not at present in a position to compete in shipbuilding with France, Italy or Germany. The lowest British tender was £99,000 per ship, whereas the price quoted abroad, apart from German builders, was as low as £47,000. Sir Alexander Kennedy, managing director of the Fairfield Shipbuilding and Engineering Company, Ltd., of Glasgow, holds the view that the breath of the shipbuilding trade is being crushed out by taxation and wages. In England and Scotland fifty percent of the shipbuilding berths are empty, and fifteen percent are occupied by vessels either canceled or on which work has been suspended. Moreover, despite the fact that shipbuilders are willing to sacrifice all profit, no new orders are forthcoming. In one English district with thirty-five berths, only two vessels are building, and twelve thousand men are idle.

Channel Steamer Anglia

One of Four 25-Knot Luxuriously Fitted Vessels Built by Messrs. Wm. Denny & Brothers, Dumbarton, for the Holyhead-Dublin Service of the London & North-Western Railway Company. The Vessel is 395 Feet Long Overall, 45 Feet molded Beam and is Certified to Carry 1,522 Passengers. Propulsion is by Twin Screw Geared Parsons Turbines Supplied with Steam From Nine Babcock & Wilcox Watertube Boilers.

Triple Screw Liner Reliance, Sister Ship of the Resolute, Latest Additions to United American Lines' Fleet for New York-Hamburg Service

Passenger Liners Resolute and Reliance

Two 20,000-Ton Steamers Commissioned by the United American Lines for Their New York-Hamburg Service

WITH the arrival in New York on April 23 of the 20,000-ton oil burning, triple screw, passenger steamer *Resolute* a new fortnightly service between New York and Hamburg, with calls at English and French channel ports, was inaugurated by the United American Lines, the operating company of the American Ship and Commerce Corporation. This service will be maintained by the *Resolute* and a sister ship, the *Reliance*. On the eastward voyage the vessels will call at Plymouth and Boulogne and on the westward voyage at Southampton and Cherbourg. The time of passage to England and France will be about 8 days and to Hamburg about 9 days.

The entry into the North Atlantic service of these two luxuriously appointed passenger liners marks an important event in the history of the American merchant marine, as the *Resolute* and *Reliance* are the largest *privately owned* passenger vessels flying the American flag. These ships were originally designed for the South American service of the Hamburg-American Line. Both were laid down in Germany in 1914, the *Resolute* at the yards of the Actien Gesellshaft Weser at Bremen and the *Reliance* at the yards of John Tecklenborg, Bremerhaven-Geestemunde, but neither was finished until after the war in 1920 when they were sold to the Royal Holland Lloyd Line. In this service they ran for a year from Amsterdam to Buenos Aires via Boulogne, Plymouth, Vigo, Lisbon, Las Palmas, Rio, Santos and Montevideo, a voyage of 6,642 miles each way.

With the transfer of these vessels to American registry W. A. Harriman, chairman of the United American Lines, selected for them the names of two of the famous American yachts which successfully defended the *America's* cup against foreign challengers. By so doing he sought to commemorate in two of the finest ships flying the American flag in the competition of commerce the achievements of two contenders which so valiantly carried the American flag in the competition of sport.

Principal Dimensions of the Resolute

Although built in different yards in Germany, the two vessels are practically duplicates. The main particulars of the *Resolute* are as follows:

Length overall	618 feet
Length between perpendiculars	588 feet
Beam	72 feet
Depth to shelter deck	43 feet 9 inches
Draft, loaded	28 feet ¼ inch
Displacement, light	16,000 tons
Displacement, loaded	23,080 tons
Deadweight tonnage	7,080 tons
Weight of fuel oil	3,300 tons
Weight of fresh water	1,500 tons
Tons per inch of immersion	78
Horsepower	15,000
Speed	16¾ knots
Number first class passengers	364
Number second class passengers	276
Number third class passengers	467
Total number of passengers	1,107

Classed at the highest rating of Germanischer Lloyds the *Resolute* and *Reliance* are of the most modern type of construction and arrangement and no expense has been spared to make the vessels conform in appointments and equipment to the highest standards in passenger travel. The hull is subdivided by a double bottom extending from the forward

S. S. Resolute—Ladies' Saloon

S. S. Resolute—Smoking Room

S. S. Reliance—Winter Garden

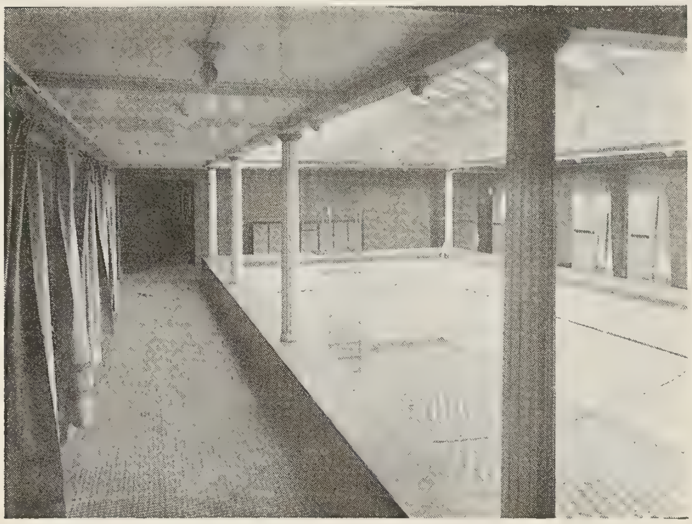
S. S. Reliance—Library and Writing Room

to the after collision bulkheads and by ten transverse watertight bulkheads carried up to the shelter deck. Above the hold and orlop decks there are in all seven decks, designated from the top, as A (Boat), B (Promenade), C (Bridge), D, E, F and G decks. All first class accommodations are amidships on A to E decks, inclusive, the second class accommodations aft on C to F decks, inclusive, and the third class accommodations forward on D to G decks, inclusive.

Propelling Machinery

Propulsion is by triple screws, the wing screws being driven at 80 revolutions per minute by four-cylinder triple expansion reciprocating engines with cylinders 29.5 inches, 49.2 inches and (two) 53.1 inches diameter by 59.05 inches stroke and the center screw at 210 revolutions per minute by a Parsons low pressure turbine taking steam from the low pressure cylinders of the reciprocating engines at 15 pounds per square inch. Seventy-one men are required for the engine room crew.

Steam is supplied to the high pressure engines on the wing screws at 240 pounds per square inch pressure by fourteen oil-fired Yarrow watertube boilers operating under Howden's system of forced draft, without superheat. The forced draft fans are operated by reciprocating engines. Each boiler has



S. S. Resolute—Swimming Pool

3,200 square feet of heating surface and 61.2 square feet of grate area and is equipped with three Vulcan burners.

The boilers are located in two boiler rooms separated by a fuel bunker having a capacity of 710 tons of oil. The total amount of fuel oil carried is 3,300 tons and the average consumption 165 tons per day. The uptakes from the boilers in the forward boiler room lead to the forward smokestack and those from the after boiler room to the center stack. The after stack, which is over the engine room is used for ventilation, exhaust from the galleys, etc.

The auxiliaries, all of which were supplied by the Vulcan Works, at Stettin, Germany, include four 115-kilowatt turbo generators, four 30-ton evaporators and two refrigerating machines.

First Class Accommodations

Accommodations for the 364 first class passengers are provided amidships extending over five decks.

On the boat deck, besides the fine open promenade space afforded, there are offered special inducements for recreation and sports in the form of an elaborately equipped swimming pool and gymnasium. The swimming pool itself measures 30 by 12½ feet and is surrounded by dressing rooms, shower baths, electric light baths and other equipment essential to its use. Aft of this is the gymnasium, fully equipped under the Zander system, alongside of which is a botanical garden and a photographers' dark room. Amidships on the boat deck is the wireless telegraph room and forward are the officers' quarters.

Except for a few special staterooms the entire promenade deck is given over to the first class public rooms and promenade. As shown by the illustrations these rooms provide all the comfort and luxury found in the best hotels on shore. In decoration, appointment and equipment they are designed to satisfy the most discriminating traveling public. The promenade space itself is 20 feet wide and extends clear around the ship with a length of 320 feet on each side. The forward part is protected against stormy weather by sliding windows.

Occupying a large space forward on the promenade deck is the winter garden. Arched by a dome of colored glass and sumptuously furnished this is used as the assembly room for dances, concerts and other entertainments. Further aft on this deck is the ladies' saloon, lighted from above by a glass dome and from the sides by broad groups of windows. Opening from the ladies' saloon on the starboard side is a spacious library and writing room which, with its arched and beautifully decorated ceiling, has an atmosphere of unusual distinction. The walls are paneled and along the inboard side are large bookcases containing the ship's library while opposite in front of the windows are writing tables.

At the after end of the promenade deck is the smoking room, paneled in mahogany, and just outside this the terrace cafe or promenade deck lounge.

The bridge deck amidships is given over entirely to first class staterooms except for the main lobby in the center containing the main office, purser's and chief steward's offices and the barber shop and ladies hairdressing parlor.

On D deck amidships is the main dining room extending the full width of the ship and in the center rising through two decks to a height of 16 feet. At the forward end of the room at the level of the bridge deck is a balcony for the orchestra. The color scheme for the dining room is pearl grey and lighting is accomplished by concealed incandescent lamps. The galley and pantry are below on E deck.

Aft of the entrance to the main dining room on the starboard side is a children's room decorated with paintings of characters familiar to readers of fairy tales and furnished with specially constructed low tables and chairs. The remainder of D deck amidships is given over to first class staterooms as is also a similar section of E deck.

The staterooms are large and well ventilated. In the first cabin bedsteads take the place of berths. Many rooms contain dressing tables, desks and chairs, in addition to the usual wardrobes and sofas. A large number of rooms are arranged for one passenger. Each room is supplied with running hot and cold water.

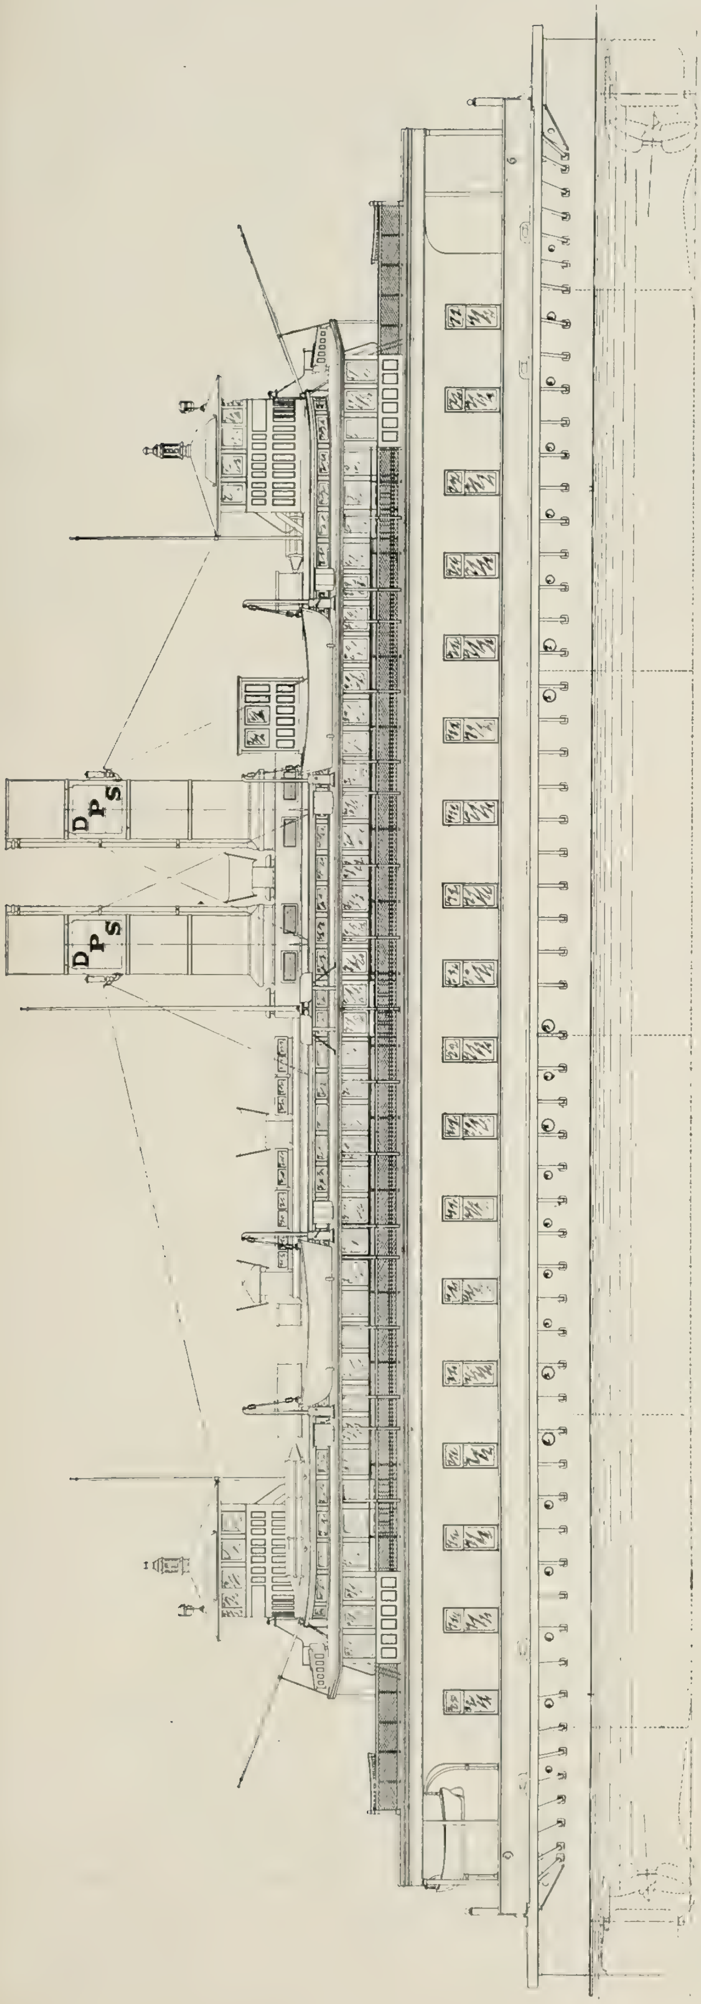
The private suites are provided with sitting rooms, baths and trunk rooms. When so desired meals are served in the suites.

Second and Third Class Accommodations

For second class passengers, whose quarters are aft, promenade space is provided on the promenade and bridge decks. The second class public rooms are on the bridge deck and include a large, pleasingly appointed dining room, a handsomely furnished social hall or lounge, a smoking room and ladies' parlor.

The staterooms differ from those in the first class accommodations mainly in that they have berths instead of bedsteads, but the fittings are up to date in every particular. Many of the rooms accommodate two passengers only.

The third class quarters, located forward, have been transformed from open berths to rooms for two and four passengers. Dining rooms, a ladies' parlor and a smoking room are provided and promenade space is available on C deck.



Outboard Profile of New Turbo-Electric Ferryboats Designed for Staten Island Service in New York Harbor

New Turbo-Electric Ferryboats for New York City

Three Turbo-Electric-Drive Vessels to Be Added to Staten Island Service in Connection with New Pier Developments

THE new pier developments on Staten Island which included the addition of twelve municipal piers to the six privately owned piers in that locality immediately brought up the question of proper facilities for handling freight to and from the seagoing vessels which will berth at these piers, and in order to meet the needs for increased ferry service the Department of Plant and Structures of New York City has prepared designs for three new turbo-electric-drive ferryboats which, when built, will take care of the needs of this new commercial enterprise.

These new ferryboats will operate between the foot of Cortlandt Street, Manhattan, and St. George, Staten Island. In view of the fact that the vessels are designed primarily to handle the trucking business to and from the piers, the lower deck will be devoted entirely to this end and will be arranged to provide four driveways. In addition to this, however, accommodations for passengers will also be provided, but the arrangements for passengers will be confined to the upper deck.

Bids for the construction of these vessels were submitted to the Commissioner of Plant and Structures on April 20 by the Staten Island Shipbuilding Company and the Tebo Yacht and Basin Company.

The Staten Island Shipbuilding Company bid $1,103,900 for two boats complete and $1,639,900 for three boats. The bid of the Tebo Yacht and Basin Company was for $1,160,000 for two boats and $1,730,000 for three boats.

Hull

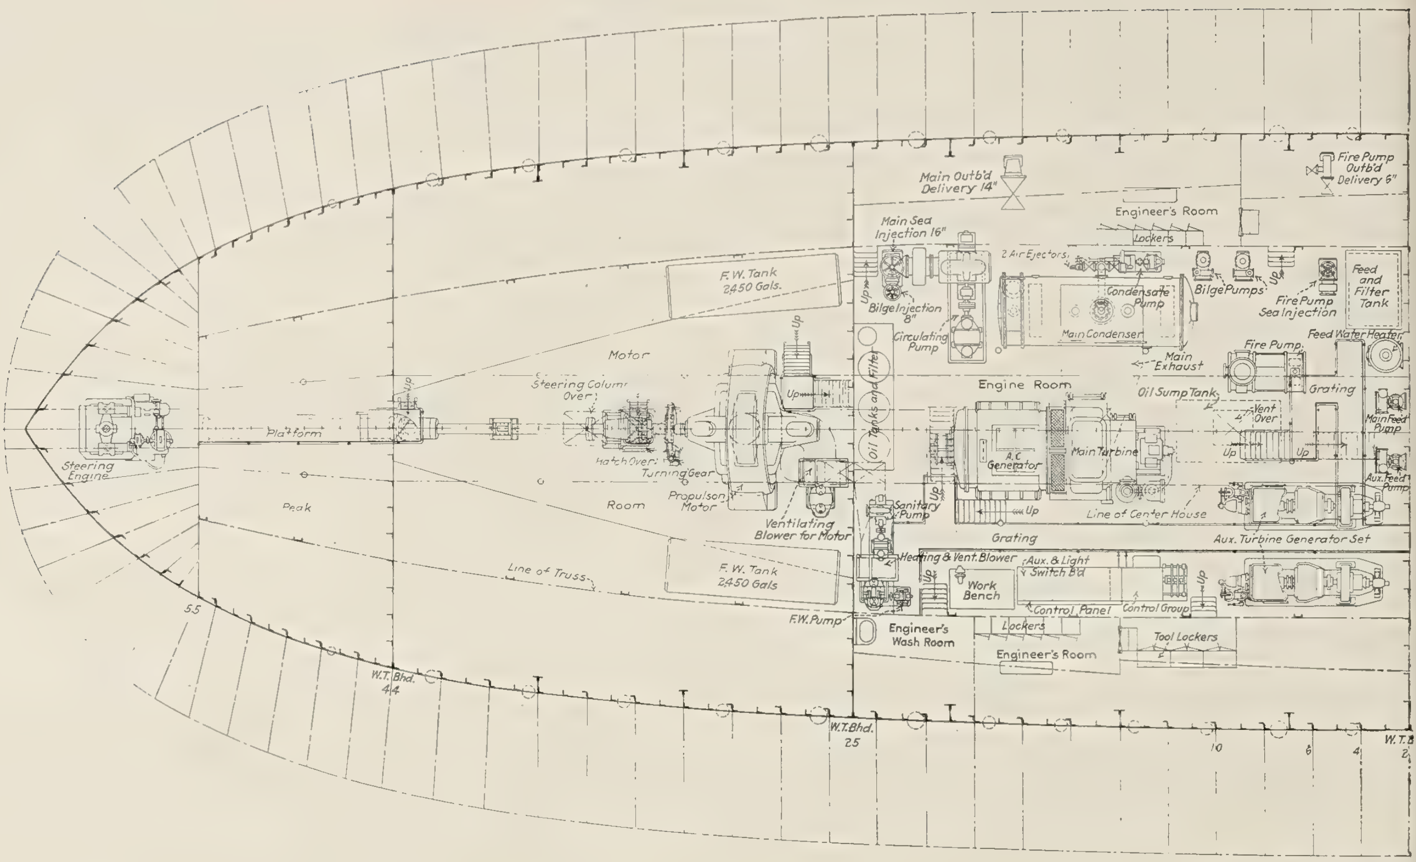
The preliminary designs of the vessels have been prepared in such a manner that either transverse or longitudinal framing may be adopted, and this point was made a subject of alternative bids from the builders. The above bids in each case were based on transverse framing and the Staten Island Shipbuilding Company stipulated a reduction therefrom of $2,100 per boat, if longitudinal framing is adopted. A deduction on the same basis of $6,000 per boat, was stipulated by the Tebo Yacht and Basin Company.

Each vessel will be subdivided by 5 transverse bulkheads extending to the main deck and arranged as shown.

The longitudinal strength of the vessels will be maintained by a longitudinal truss arranged on each side of the centerline. On account of their size and the special conditions under which these vessels will operate it is doubtful whether ferryboats of a similar nature would be suitable for any city other than New York. The machinery arrangement, however, is particularly interesting as representing the trend of modern practice for ferryboat propulsion.

Main Propelling Machinery

The main propelling machinery consists of two main electric motors, one located at each end of the vessel, both of which are operated by a single turbo generator. The main turbine will be of the impulse, marine condensing, rigid frame, three-bearing type, direct connected to the main generator. This unit will have a capacity of 2,200 horsepower at the propeller shafts. The water rate of the turbine will be approximately 10.5 pounds per propeller shaft horsepower each with 250 pounds steam pressure, 200 degrees F. superheat at the throttle, and 28.5 inches of vacuum when delivering 2,100 horsepower at the stern propeller shaft and 100 horsepower at the bow propeller shaft, excluding the power required for excitation.



Hold Plan, Showing

The speed of the turbine will be approximately 3,000 revolutions per minute when delivering the full 2,200 shaft horsepower and it will be constructed to allow a speed variation from 30 percent of normal to the maximum required. Under the normal operating conditions the total horsepower will be 1,900 or about 1,800 at the stern propeller and 100 at the bow propeller.

As is customary in installations of this type, a governor will be provided which shall limit the turbine speed to 7 percent above normal and an emergency governor of the eccentric ring type will be provided which will operate should the speed above normal reach 11 percent.

Main Generator

The main generator will be of the three phase, alternating current type, direct connected to the main turbine. It will have a capacity of 2,300-3,000 volts and a maximum operating speed of not less than 3,000 revolutions per minute. The excitation required at full load when delivering 2,200 horsepower at the propeller shafts will be approximately 20 kilowatts.

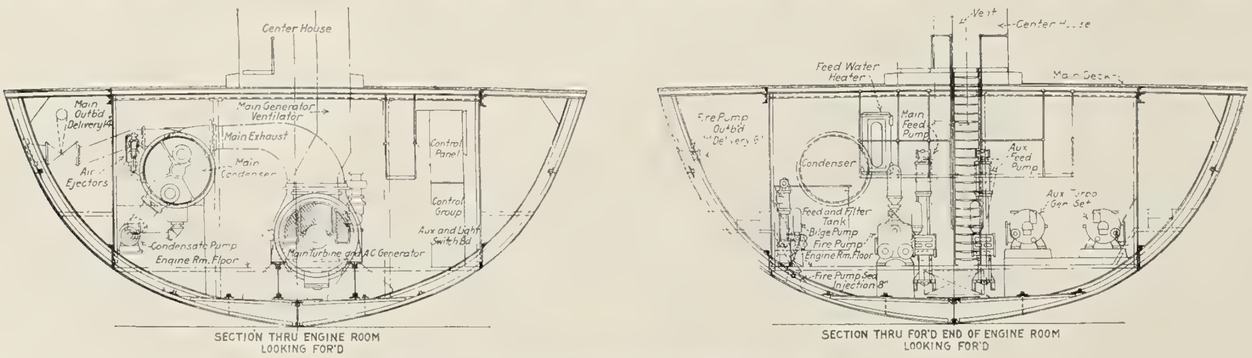
The stator frame will be made of cast iron in one piece and the punching ribs cast integral with the frame. The armature core will be built up of annealed and enameled segments of thin sheet iron designed and constructed so as to obtain a minimum core loss. Punchings will be secured to the stator frame by means of dovetailed keys and heavy cast iron flanges at each end will hold the core securely under high compression. Armature punchings will have open slots to permit the use of form wound coil with proper insulation. The winding will be made up of rectangular wire thoroughly impregnated with a high grade moisture resisting compound.

The rotor will be made of a one piece heat treated solid steel forging. This forging will form both the shaft and core of the rotor and the field portion of the magnetic circuit. The rotor winding will be made of suitable copper strips wound edgewise and insulated with mica tape.

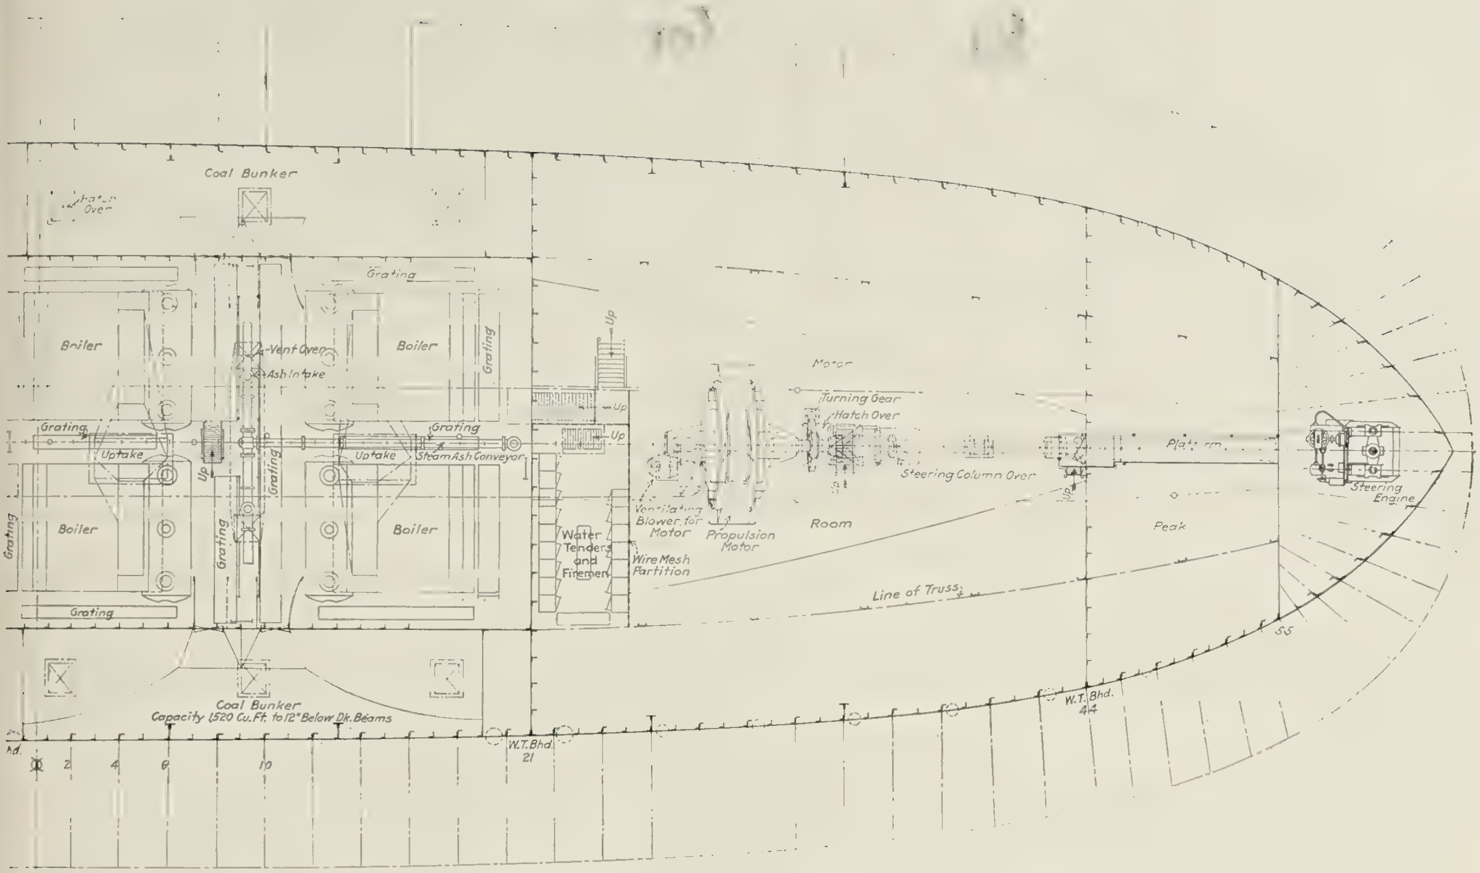
The generator will be ventilated by centrifugal fans integral with the rotor.

Main Propulsion Motors

The two main propulsion motors will be of the three-phase, alternating-current, induction type of 2,300-3,000 volts capacity. Each motor will be provided with a stator winding for operating the stern propeller at full speed and power



Transverse Sections Through Engine Room



Machinery Arrangement

(2,100 horsepower and about 176 revolutions per minute) and a stator winding for operating the bow propeller at reduced speed and low power (about 100 horsepower and 132 revolutions per minute). This speed change will probably be secured by pole changing. The outside diameter of the motors will be approximately 10 feet.

The stator frame will be made of cast iron and designed to resist deflection from strains due to weight of punchings and windings or to any magnetic pull. Frame and bearing brackets will be made watertight below the shaft center, and will be provided with means for draining any condensation that may occur.

The stator core will be built up of thin steel punchings secured to the frame by means of dovetailed keys attached to the ribs in the stator frame. Ventilation of the core and windings will be secured through radial ducts provided at suitable intervals along the length of the core and opposite similar ducts in the rotor. The stator coils will be made up of a suitable number of turns of rectangular wire with cotton and mica compound covering. The coils will be held in place in the slots by means of thin wedges of insulting material. The external ends of all coils will be laced to an insulated steel ring in such a manner as effectively to prevent vibration and this steel ring will be securely fastened to the stator frame.

The rotor spider will be made of cast steel keyed and pressed on the rotor shaft and the rotor shaft will be made of steel of sufficient size to insure rigidity under all conditions of service. The rotor core will be built up of segmental laminations made from thin steel which will be held by slots in dovetailed ribs of the rotor spider. Radial ducts and spacer fasteners will be provided similar to those for the stator. The windings will consist of two squirrel cage windings. The high resistance winding will be brazed with silver solder to the end rings and the low resistance winding will be welded to the end rings.

Bearings will be of the ball seated self-alining type split through the horizontal diameter.

The motors will be designed to operate continuously at full load and full speed on the full speed winding and at full load and full speed on the slow speed winding with a temperature rise by thermometer not exceeding 50 degrees C. based on an ambient temperature of 40 degrees C. when 13,000 cubic feet of air per minute are taken through each motor by a separately motor driven blower. When operating, the combined power factor of the stern motor and the bow

---

motor, when run at normal full speed frequency and full load, will be approximately 70 percent. The combined power factor of the stern motor and bow motor when run at one-half load on each motor, will be not less than 70 percent when the generator excitation is reduced for the half load condition.

Each motor will be provided with two 500-watt (115 volts) electric heaters.

Control Apparatus for Main Units

The propulsion motors will function as follows:

Maximum field will be applied to the alternator and the stern motor started on its full speed winding. After it has accelerated, the bow motor will be started on its slow speed winding and the field of the alternator reduced to normal. The above connections will be reversed for backing. Slow to full speed will be effected by turbine speed variation and control. All ordinary maneuvering, including speed changes, stopping, starting and backing, will be controlled by two levers mounted on the control panel; one turbine lever (turbine throttle) for varying the turbine speed and one control lever for energizing, electrically through a controller, the solenoid-operated air break contactors which control the functioning of the main propulsion units. In addition to these control levers there will be an arrangement of interlocking, manual control levers for use in emergency.

A protective device will be installed in the circuits leading to each slow speed motor winding which will trip the line contactors in these circuits in case an overload occurs on either motor when operating on the slow speed winding. An emergency connection will also be provided so that in case one motor fails the other motor can be operated in either direction on its full speed winding.

Auxiliary Turbo Generators

Two direct current turbo generator auxiliary sets of 125 kilowatts capacity each will be provided. Each set will consist essentially of an impulse turbine and a direct current,

three wire generator, of 110-220 volts capacity, operated through double reduction gears.

The turbine will be of the horizontal multi-stage type, with a water rate of approximately 21 pounds per kilowatt hour with 250 pounds steam pressure, 200 degrees F. superheat at the throttle and 28½ inches vacuum.

The turbine will be equipped with an oil-operated governor which will function at two percent overspeed and an emergency governor will be provided which will effectively shut off the steam supply at an overspeed of 10 percent.

The reduction gear, will be of the double reduction, straight line drive type, the speed reduction being approximately 3,600 to 1,200 revolutions per minute.

Generator and turbine will be mounted on the same bed plate. The generator will be flat compounded with three wire connections, etc., and of sufficient capacity to handle a 25 percent unbalanced load. An overspeed governor will be fitted which will operate on 10 percent above normal. The generator will be of the self-ventilated type.

Suitable connections will be provided to a switchboard in such a manner that either turbo generator, or both in parallel, can furnish current to the auxiliaries and the lighting circuits. The latter are to operate at 110 volts. Auxiliary motors are to take current across the outside wires of the system and operate at 220 volts.

Auxiliary Motors

All auxiliary motors will be of the marine, direct current, combined or shunt wound, commutating pole, continuous rated, self-ventilated, splash proof type, operating at 220 volts. They will be direct connected, generally, to their respective auxiliaries by means of flexible couplings.

Lubricating Oil System

A lubricating oil system will be installed for the main turbo generator, main propulsion motors and the auxiliary turbo generators. The system will include two gravity tanks located in the engine casing and connected through a duplex strainer to all bearings and thence to a common sump tank located under the engine floor. Duplicate oil pumps will draw from the sump tank through a duplex strainer and discharge through duplicate oil coolers to the gravity tanks, and connections will be fitted for by-passing the gravity tanks and discharging direct to the bearings through the strainer. The overflow from the gravity tanks will lead direct to the sump tank. In addition an independent line will be provided from the bottom of the sump tank to a pump discharging to a separator and then back to the sump tank.

Air Compressor

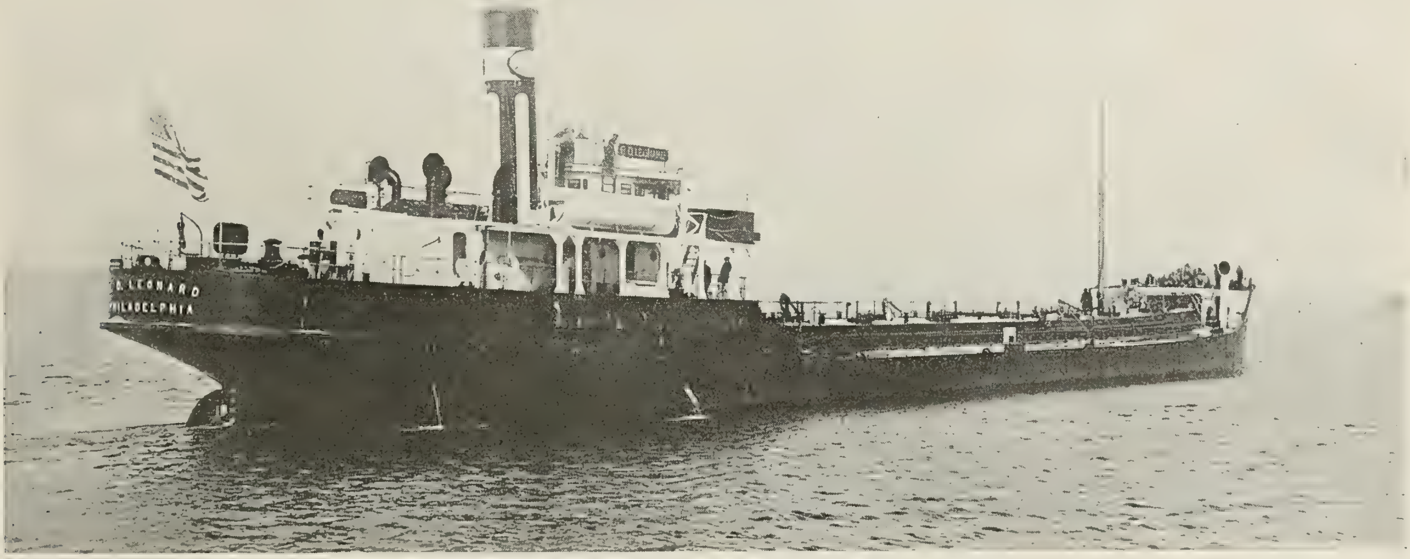
A single air compressor will be provided for blowing out coils, cleaning electrical machinery, etc. It will be of the stationary, motor driven, automatic control type with a displacement of approximately 15 cubic feet of air per minute.

The new ferryboats, when added to the present St. George ferries operating from the Battery, will add considerably to the facilities afforded for passenger and freight transportation to Staten Island. These new boats will be faster than those now in operation and it is also expected that they will operate more economically, resulting in a saving of from 20 to 22 tons of coal per day. The completion of the new municipal piers will increase in a very large measure the trucking traffic to the Island but these new, large and speedy ferryboats of the four driveway type are expected to amply provide for the efficient handling of this traffic.

Atlantic Refining Company Tanker R. D. Leonard Completed

ANOTHER vessel was added to the Atlantic Refining Company's fleet when the turbine driven single screw tanker *R. D. Leonard* was delivered to the company by the Harlan plant, Wilmington, Del., of the Bethlehem Shipbuilding Corporation, Ltd., on February 17.

The ship was built in accordance with Lloyd's 100 A-1 class for vessels to carry oil in bulk. The total carrying capacity is about 2,640 tons deadweight on a mean draft of 17 feet 1⅞ inches, with an oil cargo capacity of about 2,450 tons.



Atlantic Refining Company's New Tanker R. D. Leonard

The principal particulars of the vessel are as follows:

Length overall	276 feet 10 inches
Length between perpendiculars	266 feet 0 inches
Beam molded	39 feet 0 inches
Depth molded	20 feet 0 inches
Type of engine	Turbine
Boilers	Babcock & Wilcox
Number of boilers	2
Steam pressure, pounds per square inch	225
Kind of fuel	Oil
Speed on trial trip, knots	9.68

The propelling machinery consists of a single De Laval steam turbine, with double reduction gears, capable of de-

veloping a normal shaft horsepower of 750 at 95 revolutions per minute, and a maximum shaft horsepower of 900 at about 101 revolutions per minute. The Bethlehem-Dahl mechanical oil burning system is installed, operating under either natural or forced draft.

The oil pumping machinery consists of the following: Two vertical duplex compound cargo pumps, 7 inches by 12 inches by 10 inches by 12 inches stroke; fuel oil transfer pump, horizontal duplex type, 6 inches by 5¾ inches by 6 inches stroke; and two fuel oil service pumps, horizontal duplex type, 4½ inches by 2¾ inches by 4 inches.

The main feed pump and general service pumps are both vertical simplex, 10 inches by 6 inches by 18 inches stroke.

The deck machinery was built at the Moore plant of the Bethlehem Corporation, at Elizabeth, N. J., and consists of an 8-inch by 7-inch spring quadrant type steering gear with horizontal engines; an 8¼-inch by 8-inch spur-gear windlass; and a 6¼-inch by 8-inch steam self-contained gypsy-capstan.

Steam Pilot Boat Maryland Completes Her Trials

THE new steam pilot boat *Maryland,* built for the Association of Maryland Pilots, at the Tebo plant, Brooklyn, N. Y., of the Todd Shipyards Corporation, from the designs and specifications of Cox & Stevens, naval architects, New York, was given a successful trial trip at sea off New York harbor on March 29. The *Maryland* will be put in service as the station vessel off Cape Henry.

Pilot Boat Maryland

Principal Dimensions

Length over all	150 feet—0 inches
Length between perpendiculars	140 feet—3 inches
Beam molded	25 feet—0 inches
Depth molded	15 feet—7 inches

Intended for Steam Trawler

The vessel was originally designed as a steam trawler by Cox and Stevens. After construction was started she was purchased in an incomplete condition by the Association of Maryland Pilots. The design was then revised so that the vessel as now completed represents, both in construction and equipment, an ideal type of pilot boat.

The hull is constructed of steel in excess of Lloyd's requirements. The vessel has two pole masts and is flush decked with a straight stem and a turtleback forward. She has a well proportioned elliptical stern aft, the freeboard being ample and the sheer unusually lively.

There is a continuous steel deck house on the main deck. At the forward end of the main deck house there is a pilot house containing the captain's room and navigating room.

At the after end is a large smoking room comfortably furnished with tables, seats, and so forth, which communicates directly with the pilots' living quarters which are on the deck below.

Forward of the smoking room on the starboard side is the chief engineer's stateroom and on the port side a stateroom for the assistant engineer, both communicating directly with the machinery space which is just forward of their staterooms.

The steering engine is located on the main deck just forward of the machinery compartment.

Forward of the boiler enclosure is the galley and the pantry and at the extreme forward end of the house is the main room, which is handsomely furnished and of sufficient size to permit ample accommodations for the pilots.

The space under the turtleback forward contains the capstans and also the lavatories and toilets as well as storerooms for deck supplies and other equipment.

At the after end of the main deck over the quadrant are fitted large stern gratings and there is a very heavy towing bitt as well as the usual equipment of chocks, bollards and cleats.

Pilots' Quarters

Below deck, the pilots' main living quarters occupy the after part of the vessel and are unusually large and comfortably arranged. In this compartment are accommodations for sixteen pilots, each having a separate bunk and locker space for clothes. A bath room and ample wash facilities are provided.

Crew's Quarters

Below, forward of the boiler room, are the quarters for the crew proper and also accommodations for apprentices. On the starboard side is a large refrigerator, the ice machine room being adjacent thereto and also staterooms for stewards, messman and cabin boy, while on the port side are staterooms for the oilers and firemen as well as a large storeroom for provisions.

In the lower forecastle, which is arranged for apprentices and for additional members of the crew, are ten berths with the usual transoms and clothes lockers. Forward of this space is a storeroom with chain locker underneath.

Machinery

The engine, which is of the compound type, having cylinders 18 inches and 38 inches in diameter with a 26-inch stroke develops 650 horsepower. Steam is supplied by a Scotch boiler 14 feet 6 inches in diameter and 12 feet in length. The boiler has three furnaces and 2,500 square feet of heating surface. A donkey boiler is also installed.

Auxiliary Machinery

The following auxiliary machinery is installed:

Circulating pump—centrifugal type—6-inch discharge.
Feed pump—horizontal duplex type—$7\frac{1}{2} \times 5 \times 10$.
Donkey pump—vertical duplex type—$7\frac{1}{2} \times 4\frac{1}{2} \times 8$.
Fire and bilge pump—horizontal duplex type—$7\frac{1}{2} \times 4\frac{1}{2} \times 8$.
Fresh water pump—horizontal duplex type—$4\frac{1}{2} \times 3 \times 4$.
Generator—10 kilowatt—and storage batteries.
Ice machine—one-ton capacity.

Navy Machinery Specifications.—The Bureau of Engineering, of the Navy Department, is furnishing the Engineering Schools of many of the colleges of the country with copies of its General Specifications for Machinery. These specifications represent modern practice in naval engineering, and with their several appendices describing methods of inspection, etc., are practically text-books on this highly specialized subject.

Fig. 1.—S. S. Peninsula State, the Last of a Group of 535-Foot Passenger Vessels Built by the New York Shipbuilding Corporation, Camden, N. J., for the Shipping Board, on Her Trial Trip Early in February. The Peninsula State Has Been Allocated to the United States Lines

America Develops New Atlantic Passenger Service

United States Lines to Operate Nine "State" Ships Specially Adapted for Passengers of Moderate Means—Equivalent of Second Class Accommodations Offered to Pasesngers at Third Class Rates

ONE of the features of transatlantic passenger traffic this year will be the facilities afforded European travelers by the United States Lines to sail in American ships.

This farsighted steamship agency has arranged to operate nine Shipping Board vessels of the "State" class on the North Atlantic run and in addition to providing cabin accommodations of the highest type will cater particularly to passengers of limited means who contemplate going abroad. The vessels will be arranged to maintain a bi-weekly schedule to Europe and this will be increased to three sailings weekly should conditions warrant.

Plans for reconditioning the vessels with a view to increasing the comfort of passengers and extending the accommodations to allow for substantial reductions in rates have been prepared under the supervision of Mr. Carl E. Petersen, naval architect for the United States Lines.

Vessels Being Reconditioned

At the present time the *Old North State* and *Panhandle State* are cabin ships, and the *Centennial State* carries cabin and third class. The *Granite State* and *Blue Hen State* will each carry 176 cabin and about 400 third class in rooms, both of these ships being scheduled to sail in June. The *Lone Star State* and the *Peninsula State* carry about 205 first class and 234 third class passengers and the *Hawkeye State* and the *Buckeye State* will be fitted up to carry 250 first class and 320 third class passengers.

The conversion of the *Old North State* has recently been completed at the Morse Dry Dock and Repair Company's plant at Brooklyn, N. Y., and this vessel entered the New York-Plymouth-Cherbourg-London service on March 14. The work on this vessel is similar to that proposed for the cabins of the 502-foot class vessels and the changes consisted chiefly in removing one of the two beds from each room and substituting a sofa bed at the outboard side ingeniously arranged to accommodate two persons and installing a folding Pullman berth over the remaining bed. The new arrangement is shown in Fig. 2 and by this means accommodation is provided in each room for 1, 2, 3 or 4 persons.

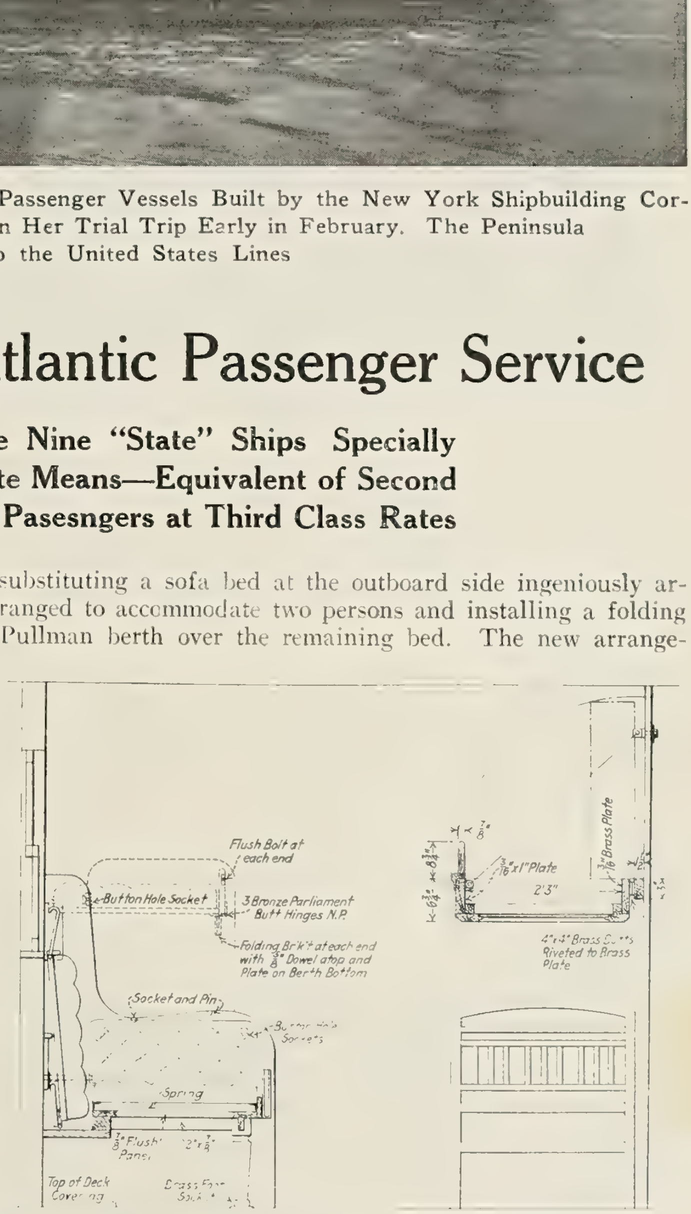


Fig. 2.—Typical Section, Showing New Arrangement of Cabin Staterooms

Changes in Third Class Accommodations

The most radical changes are being made in the third class accommodations. It is generally known that the greatest returns to a steamship company are made from the lowest class accommodations and on account of this the pre-war

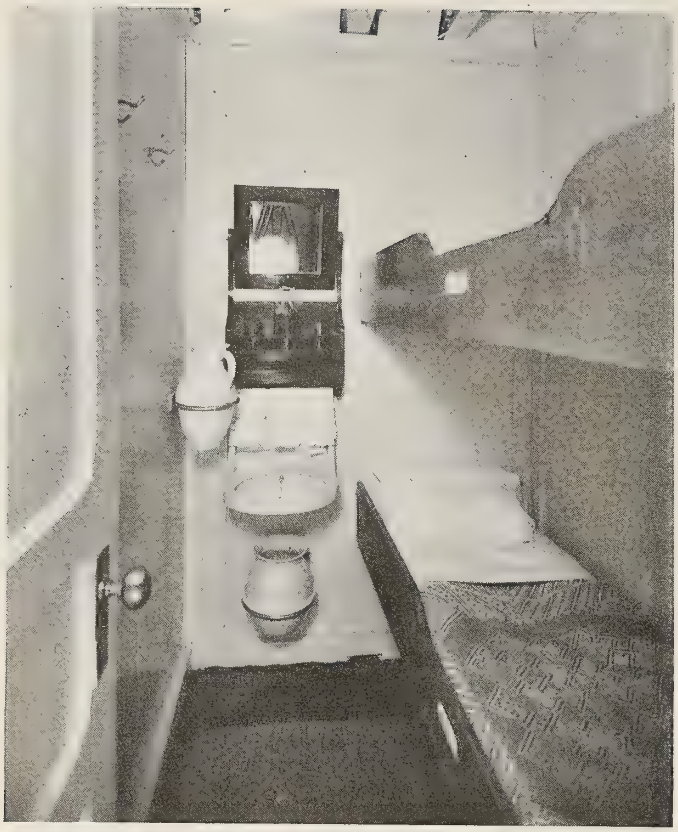

Fig. 3.—S. S. Lone Star State—Typical Third Class Stateroom

custom was to provide accommodations for the greatest number and the comforts afforded were a minimum. This has all been changed under the new plans of the United States Lines and in these American ships every means will be provided for adding to the comfort of this class of traveler.

The old time steerage quarters have been replaced with neat staterooms arranged for two, three, four or six persons and fitted with lavatories and other conveniences. The decks are covered with carpet and composition decking and built-in berths with hardwood leeboards and metallic springs are provided.

Public Rooms

In addition to the individual staterooms there have been provided for the third class passengers public rooms, including a ladies' lounge and a smoking room for men. Well filled bookcases, a victrola and a piano add to the facilities for pleasure. A large dining room is provided and a feature of this room is the substitution of swivel chairs for the long benches which were formerly used. The piano is located in this room and arrangements are made for removing the chairs and tables, in this manner providing a clear deck space for dancing. A barber shop adds to the conveniences offered and ample promenade deck space is provided for outdoor lounging and recreation.

Every need of the prospective passenger has been considered. The decorations have been studied and adapted to please the most fastidious. Upholstered settees invite one to rest and the whole scheme has been worked out to such a nicety that what is really offered is second class accommodations at third class rates.

Old-Fashioned Steerage Abolished

This new idea is bound to meet with universal approval and many who have hesitated about undergoing the hardships of a steerage passage to Europe will now find it within their means to go abroad in American ships and be assured of every comfort.

Not of the least importance in the new plans of the United States Lines is the reduction in price afforded. One can now travel in comfort to Queenstown, Plymouth or London for $85.00 or to Bremen for $103.50.

The plans and specifications for the conversion of these vessels were prepared by the technical staff of the United States Lines and the work is being supervised by Mr. Petersen, their naval architect, in collaboration with Mr. A. D. Woods of the Shipping Board. The work on the *Lone Star State* was completed on March 17, that on the *Peninsula State* on April 16 and that on the *Centennial State* on April 28 at the Robins Dry Dock and Repair Company's plant in Brooklyn.

Every effort is being made by the Shipping Board through Mr. T. Rossbottom to provide an incentive for Americans to sail in American ships and, while the cost of reconditioning this fleet involves a heavy expenditure, it is expected that a return more than offsetting it will be derived from increased patronage. That such will be the case is already indicated by the increasing demands for reservations which are constantly coming in.

The vessels of the United States Lines are already booked solid for passage to Europe until the 26th of July and practically full bookings are carried for the return trip extending to the middle of October.

Motorship Hauraki Built for the Union Steamship Company of New Zealand

Large British Steamship Companies Build Motorships

First Diesel-Engined Vessels Completed for Union Steamship Company and Royal Mail Steam Packet Company

By Our Special London Correspondent

In spite of the shipbuilding depression in Great Britain and the fact that no orders of any consequence have been placed during the past twelve months, an increasing number of motorships have been completed, since orders were placed two years ago or more which have not yet been fulfilled.

The *Hauraki,* which ran her trials in the Clyde in March, is the first oil engined ship built for the Union Steamship Company of New Zealand (owners of 82 steamers), and it is understood that she will trade between Vancouver and New Zealand, being the first ship with internal combustion engines to be placed on this route.

Cargo Motorship Hauraki

She was built by William Denny & Brothers, Dumbarton, and in general hull form and dimensions is practically identical with the motor passenger liner *Domala,* of which a full description was published in the February issue of this journal. The *Hauraki,* however, is purely a cargo ship on which none of the passenger accommodation of the *Domala* is included.

The main dimensions are as follows:

Length overall	464 feet
Length between perpendiculars	450 feet
Maximum beam	58 feet
Depth to the upper deck	35 feet 6 inches
Deadweight capacity, including fuel	10,850 tons

Comparison With Similar Steamships

The engine room is amidships and there are two cargo holds forward and two aft. In the double bottom is carried oil fuel to the extent of about 1,000 tons, which will give a radius of action of some 18,000 miles. As the vessel will be engaged upon long distance services, this large radius of action is an asset of considerable importance and the *Hauraki* will be able to bunker at San Francisco, where oil prices are low, and make the round voyage to New Zealand and back without having to take on more fuel.

It is interesting to note that the machinery of the *Hauraki*

Royal Mail Steam Packet Company's Motorship Lochkatrine

weighs approximately the same as that of a corresponding steamer including the boilers, but in the motor vessel there is an additional cargo capacity due to the absence of bunkers, this representing an extra profit earning space of several thousand cubic feet.

Air Compressors Driven from Main Engines

In many respects the machinery installed in the *Hauraki* is similar to that fitted in the *Domala*. In the latter ship, however, it was essential to obtain the maximum horsepower on the shaft with a given cylinder dimension and it will be remembered that for this reason the injection air compressors were not driven off the main engines but coupled to separate Diesel motors. In the *Hauraki*, engines of the same size as those installed in the *Domala* are used but they drive their own air compressors so that although the indicated power of the machinery of the two ships is the same, the effective or shaft horsepower in the *Hauraki* is some ten percent less, this being absorbed by the compressors.

A further result of this rearrangement is that the auxiliary machinery in the *Hauraki* is simplified and the only air compressing plant beyond that on the main propelling engines is an electrically driven compressor coupled to a 230 horsepower motor.

Propelling Machinery

The propelling engines were built by the North British Diesel Engine Works at their new factory erected specially for the construction of marine Diesel machinery. The four-cycle principle is adopted and the motors are of the eight cylinder type with cylinders 26½ inches bore and 47 inches stroke. The low speed of rotation, namely 96 revolutions per minute, at full power is noteworthy in view of the fact that in most four-cycle Diesel engines of this output the speed is about 115 revolutions per minute.

The chief novelty in the detailed design of these engines, and it is one which has not attracted altogether favorable comment, is that in reversing, before the valve levers can be brought over the astern cams, the camshaft is allowed to fall bodily and then move fore and aft. The system has, however, worked satisfactorily on the *Domala* and is apparently completely successful in service. The arrangements of the injection air compressors have never previously been adopted and it is interesting to see that each engine has two three-stage compressors driven from the crankshaft by a connecting rod of V-section. On trials a speed of 13¼ knots was attained but the average sea speed will be in the neighborhood of 12½ knots when it is anticipated that the fuel consumption will not exceed 14 to 15 tons daily.

Like the vast majority of British built motorships, the auxiliary machinery on the *Hauraki* is wholly electrically driven. The generating plant comprises three 200 brake horsepower four cylinder Diesel engines of the North British type, driving 220 volt dynamos. At sea one set will be sufficient for all purposes. When loading or discharging cargo two plants will be required, so that one will always stand in reserve. The cargo handling machinery is exceptionally complete and 12 electric winches are fitted on deck.

Two further sets of twin screw machinery of exactly similar type to that installed in the *Hauraki* are now being built by the North British Company, one for a cargo ship and the second for a motor passenger liner for the British India Steam Navigation Company.

The Lochkatrine—a 14,000-Ton Motorship

Since the middle of February of this year no fewer than four standard motorships, each of 14,000 tons deadweight, have been completed on the Clyde. This is an indication, first, of the way in which standardization in oil engine building is proceeding and, secondly, of the confidence now felt in large motorships. Apart from the fact that some of them are intended for special trades and have larger refrigerating capacity than others, they are identical in every detail and the cost of construction is thereby reduced.

One of these ships, the *Lochkatrine*, of which an illustration is reproduced, represents the Royal Mail Steam Packet Company's first incursion into motorship owning. In conjunction with their associated concern, the Holland-America Line, they are building six motorships of the same size and type, all of which are destined to trade between London and Pacific Coast ports via the Panama Canal, a new service which the Royal Mail Steam Packet Company is now opening out. Clearly British shipowners are attacking the motorship problem in no niggardly spirit.

The following are the main details of the *Lochkatrine:*

Length overall	502 feet
Length between perpendiculars	485 feet
Maximum beam	62 feet
Depth	38 feet 6 inches
Gross tonnage	9,500
Deadweight tonnage	14,000
Indicated horsepower	6,400
Speed, knots	13-13½

There is comparatively little to be said concerning the machinery installation of the *Lochkatrine* as it represents the standard Burmeister and Wain practice as followed by the builders, Harland and Wolff. The two eight cylinder engines of 3,200 indicated horsepower each have cylinders 740 millimeters diameter and 1,150 millimeters stroke, the propeller speed being 115 revolutions per minute. Fuel consumption, including the oil required for driving the auxiliary machinery, works out at 20 tons daily, which is rather less than a quarter of the weight of coal needed in a corresponding coal fired steamer.

Electrical Equipment

The engine room represents something in the nature of a small central electric generating station for there are no fewer than four 100 kilowatt generators coupled to three cylinder Diesel engines of 150 brake horsepower. At sea, although one engine is sufficient to supply the power required for the auxiliary generating plant, two are actually kept in operation as it is considered that by running them on light loads their life is prolonged and the attendance necessary is considerably decreased. It is true that the fuel consumption is slightly higher than it otherwise would be, since it is clearly uneconomical to run Diesel motors at about one-third full load but in any event the oil required for this purpose is so small that the point is insignificant.

On deck, where all the winches are electrically operated, there are seven of the new four barrel type known as the McFarlane design which are capable of working four derricks at a time. Eight 7-ton electric winches of the ordinary pattern are also fitted on deck and the anchor windlass, steering gear and all engine room pumps are coupled to electric motors. There is only a small heating boiler installed which is kept in operation when the ship is in a cold climate.

The other three sister ships which as previously mentioned have been in commission since February, are the *Dinteldyk* for the Holland-America Line, and the *Glengarry* and *Glenbeg* for the Glen Line, which already has two vessels of the same size in regular service.

Shipping Board Vessels to Be Named After Presidents of the United States

THE Shipping Board has decided to rename the 502- and 535-foot passenger and cargo ships now named with state nicknames, such as *Nutmeg State*, and also the *Leviathan*, after presidents of the United States. Eighteen ships are to be renamed, not including the *George Washington* and the *America*, nor four ships in South American service, the *Southern Cross*, the *Western World*, the *Pan-American*, and the *American Legion*.

Mauretania Converted Into an Oil Burner

Improvement Reduces Boiler Room Force by 228 Men and Shortens Time of Fueling from 3 Days to 7 Hours

THE famous Cunard liner *Mauretania,* which was built by Swan, Hunter and Wigham Richardson, Limited of Wallsend-on-Tyne, England, and delivered to her owners in the fall of 1907, has recently arrived in New York on her maiden voyage as an oil burner. The work of converting this vessel to an oil burner was assigned to the Swan, Hunter and Wigham Richardson yard last September and it took a little less than six months to complete the job.

In addition to the oil burning system, the ship underwent extensive repairs and alterations. There had been a fire on board the ship when she was at Southampton last summer, which destroyed a few cabins on the deck below the first class dining room. All of this accommodation was restored. The whole of the dining room deck, however, had to be dismantled, the steel plates removed and the deck beams taken out and made fair. The whole of the beautiful carved oak panels and pillars in the magnificent dining hall were taken down and scraped and finished with beeswax polish, this restorative greatly enhancing its beauty. A large amount of similar work was done to the music room and lounge, the smoking room, the library, the second class public rooms and to a large number of staterooms.

Holds the Speed Record

The speed record of the *Mauretania* has been unsurpassed. Messrs. Swan, Hunter and Wigham Richardson, Limited, originally contracted to guarantee a round voyage across the Atlantic and back, under picked conditions, at 24½ knots. The performance of the ship greatly exceeded expectations, for in one year she did 27 consecutive trips acrosss the Atlantic in all weathers, at an average speed of 25½ knots. Her fastest voyage all the way across the Atlantic averaged 26.06 knots, 27 knots being run for one whole day. No other ship has been able to touch this performance, which is a very remarkable record.

As the competition in speed between rival shipowning companies in the North Atlantic has died down, it is quite possible that the Cunard Steamship Company will not try to see what is the highest speed at which the *Mauretania* can run with oil fuel. All the same, it is certain that she can show an even better performance than her record of 26.06 knots average speed across the Atlantic, if required.

Principal Characteristics

Length over all	790 feet 0 inches
Breadth	88 feet 0 inches
Molded depth to shelter deck	60 feet 6 inches
Draft to freeboard	36 feet 2½ inches
Launching weight including cradle	16,800 tons
Gross tonnage	32,000 tons
Displacement tonnage	44,640 tons

Main propelling engines—2 high pressure and 2 low pressure ahead turbines, and 2 astern Parsons turbines, 180 revolutions per minute.

Boilers—23 double ended and 2 single ended cylindrical boilers working under Howden's forced draft, with a steam pressure of 195 pounds per square inch.

Number of furnaces	192
Grate area	4,060 square feet
Heating surface	150,000 square feet

The boilers are divided into four groups, each in a separate watertight compartment. The uptakes lead to four elliptical funnels. The whole range of the boiler rooms is protected on each side by continuous watertight bunkers, which have now been made oiltight to carry oil fuel.

The former coal carrying capacity of the side bunkers, including a forward cross bunker, was about 6,000 tons. The oil carrying capacity of the side bunkers alone is now 5,350 tons. This excludes the forward cross bunker which is not used for fuel.

The installation of oil burning apparatus was carried out by the Wallsend Slipway and Engineering Company, the builders of the ship's turbines and boilers. The oil burning apparatus is of the Wallsend-Howden system, which has a world-wide reputation for high efficiency.

Oil Burning Installation

Each boiler room has a transfer pump to bring oil to a settling tank which is provided with heating coils to bring the oil to a proper degree of fluidity before it is passed to the burners. In each boiler room there is a spare heating and pumping unit as a standby. Oil is loaded into the ship at four points, two on each side above the main deck. There is a wonderfully complete set of piping and valves, so that oil may be supplied to or pumped from any one tank at will. Air escape pipes are fitted to every oil tank and they can also act as overflow pipes with connection to the main pipe lines on each side of the ship.

The ship had accommodation for 198 firemen and 120 trimmers.

Owing to the fact that the ship is now burning oil fuel, the total number of boiler room attendants will now be only 90. This means dispensing with the services of no less than 228 men, which is a remarkable economy in addition to the greater efficiency gained in the consumption of fuel by the use of oil burners.

The *Mauretania* can now be fueled in seven hours as compared with three full days for coaling. This permits her to make a complete turnaround every three weeks whereas under coal it required four weeks. With oil stowage, some of the space formerly occupied by the coal bunkers is made available for other purposes. This is also true of the space occupied by the 228 extra men that are necessary to man the ship as a coal burner so it is apparent that, even if the price of oil is increased to a point where it would be more economical to burn coal in a freight ship, the advantages of space, personnel and turnaround would still favor the use of oil in the large express liners.

120-Ton Sperry Gyro-Stabilizer to Be Installed in Hawkeye State

A GROUP of prominent naval architects and shipping men were given an opportunity to witness a test of a 120-ton Sperry gyro-stabilizer at the plant of the Westinghouse Electric and Manufacturing Company at South Philadelphia on Thursday, April 13. This stabilizer is to be installed in the Shipping Board steamer *Hawkeye State,* which is now running between Baltimore and Honolulu.

At a luncheon which preceded the inspection, the inventor, Mr. Elmer A. Sperry, explained that it was possible for a relatively small stabilizer to control a large ship and keep her on an even keel because it absorbed the wave increments at their inception. Rolling, he asserted, was due to a piling up of wave increments but the stabilizer prevented such an accumulation of forces and, for this reason, it could be placed most anywhere in a ship without unduly stressing the structural members of the vessel.

Southern Pacific Oil Tanker Tamaihua, of 17,200 Tons Deadweight

Southern Pacific Oil Tanker Tamiahua

Largest Merchant Vessel Built on the Pacific Coast —Details of Propelling Machinery—Trial Trip Data

By Henrik Greger*

THE continued demand for oil in the past few years gave impetus to great activity in the building of tanker tonnage by many of the various oil companies. The Southern Pacific Railway Company, which uses oil-burning locomotives exclusively and has a large number of oil-burning vessels, recently added to its fleet the S. S. *Tamiahua* built by the Moore Shipbuilding Company, Oakland, Cal. The vessel was designed and constructed under the supervision of A. S. Hebble, superintending engineer of the Southern Pacific Company-Atlantic Steamship Lines, and represents the most advanced ideas and practices in tank ship design.

The vessel has a total deadweight carrying capacity of 17,200 tons and is of the following general dimensions:

Length overall	516 feet 4 inches
Length between perpendiculars	500 feet
Depth molded	39 feet
Beam molded	71 feet
Mean draft	29 feet 3 inches
Speed	11 knots

The propelling machinery located aft, with separate engine and boiler rooms, consists of a vertical inverted quadruple expansion engine built by The Hooven, Owens, Rentschler Company, Hamilton, O., especially designed for the vessel.

The vessel is a single screw tank ship of the shelter deck type, with straight stem and elliptical stern, rigged with three steel pole masts. There are complete steel shelter, main and lower decks with an expansion trunk in way of the oil tanks.

The hold is divided into ten tanks with a centerline bulkhead extending under deck, dividing the tanks into port and starboard compartments. The wing spaces between the main and upper deck in way of the main oil tanks are divided into six compartments on each side and fitted as summer tanks. The pump room is located amidships. A fuel oil tank is fitted between the cargo tanks and the boiler room with a cofferdam between the fuel tanks and the boiler room. A double bottom is fitted in the engine room and boiler room for carrying fresh water or ballast.

Accomodations for the captain and deck officers are provided in a double tier of steel deck houses amidships. These houses are raised 3 feet 6 inches above the deck in order to be free of any gasses that might leak through the tank tops. The wheel house and chart house are of steel, built on top of the upper house. Quarters for the engineers, firemen, messrooms, etc., are provided in a steel deck house on the shelter deck abreast of the engine casing. The galley is located aft of the machinery casing on the shelter deck. Quarters for petty officers, seamen, cold storage, hospital and storerooms are located at the after end of the upper deck abreast the machinery casing. A steel house is provided on the after shelter deck fitted with an auxiliary steering gear. The top of this house is fitted with a warping bridge.

The vessel is built on a combined system of longitudinal and transverse framing of the Isherwood system, with scantlings and material as required by the American Bureau of Shipping classed A-1.

Cargo Oil Pumps

The cargo oil pumps consist of two horizontal duplex compound pumps with cylinders 19 by 30 by 16½ by 24 inches. Each pump is capable of discharging 3,500 barrels of oil per hour. The pumps have 18-inch suctions and 14-inch discharges. They take suction for a 14-inch main from both the forward and after ends of the vessel, which gives an exceptionally low velocity of oil in the suction lines. These pumps are designed with large valves and have 135 percent valve area in the oil ends. In addition, there is a stripping pump of the vertical duplex type, 16 by 10 by 18 inches, connected to an independent system of piping for stripping the cargo tanks to a lower level than it is possible to take the oil with the main pumps. The fuel oil feed pumps are of the horizontal duplex type, 7½ by 5 by 10 inches.

There are three single ended Scotch boilers with four furnaces in each boiler. The boilers are 15 feet 9 inches inside

*Chief engineer, Marine Department, Hooven, Owens, Rentschler Company, Hamilton, Ohio.

diameter, 12 feet long outside of the heads and are built for a working pressure of 230 pounds per square inch. The total effective heating surface of the boilers is 9,900 square feet. The furnaces are 41 inches inside diameter with 2¾-inch tubes. The boilers are fitted with heated forced draft and are arranged for burning oil.

There are two 84-inch forced draft fans manufactured by John Reid and Company, driven by twin 8 by 6-inch engines, with one engine in reserve. These fans are capable of producing 1-inch air pressure at the burners.

There are two main feed pumps of the vertical simplex type, 12 inches by 8 inches by 24 inches.

Auxiliaries

The main condenser has a cooling surface of 11,000 square feet and the auxiliary condenser a cooling surface of 6,000 square feet.

The main air pump is driven off the main engine and is 30½ inches diameter by 25½ inches stroke. The main circulating pump of 6,500 gallons capacity is driven by two vertical engines, each 10 inches diameter by 12 inches stroke. The auxiliary circulating pump, 5 inches in diameter, is driven by a 6½-inch by 6-inch vertical engine.

The bilge and sanitary pumps, each 6 inches diameter by 25½ inches stroke, are connected to the main engine. The feed pumps are of the independent vertical simplex type, 12 inches by 8 inches by 24 inches. The fire and bilge pumps are independent vertical duplex, 12 inches by 7 inches by 12 inches, and the sanitary pump is independent vertical duplex, 7½ inches by 5 inches by 10 inches. The evaporator feed pump, refrigerator, circulator and fresh water pumps are all duplicates, of the horizontal duplex type, 4½ inches by 2¾ inches by 4 inches.

The auxiliaries include two 15 kilowatt generator sets, a No. 30 Reilly multicoil feed water heater, two 35-ton evaporators, a 1,000-gallon distiller, a 3-inch twin grease extractor and two metropolitan injectors.

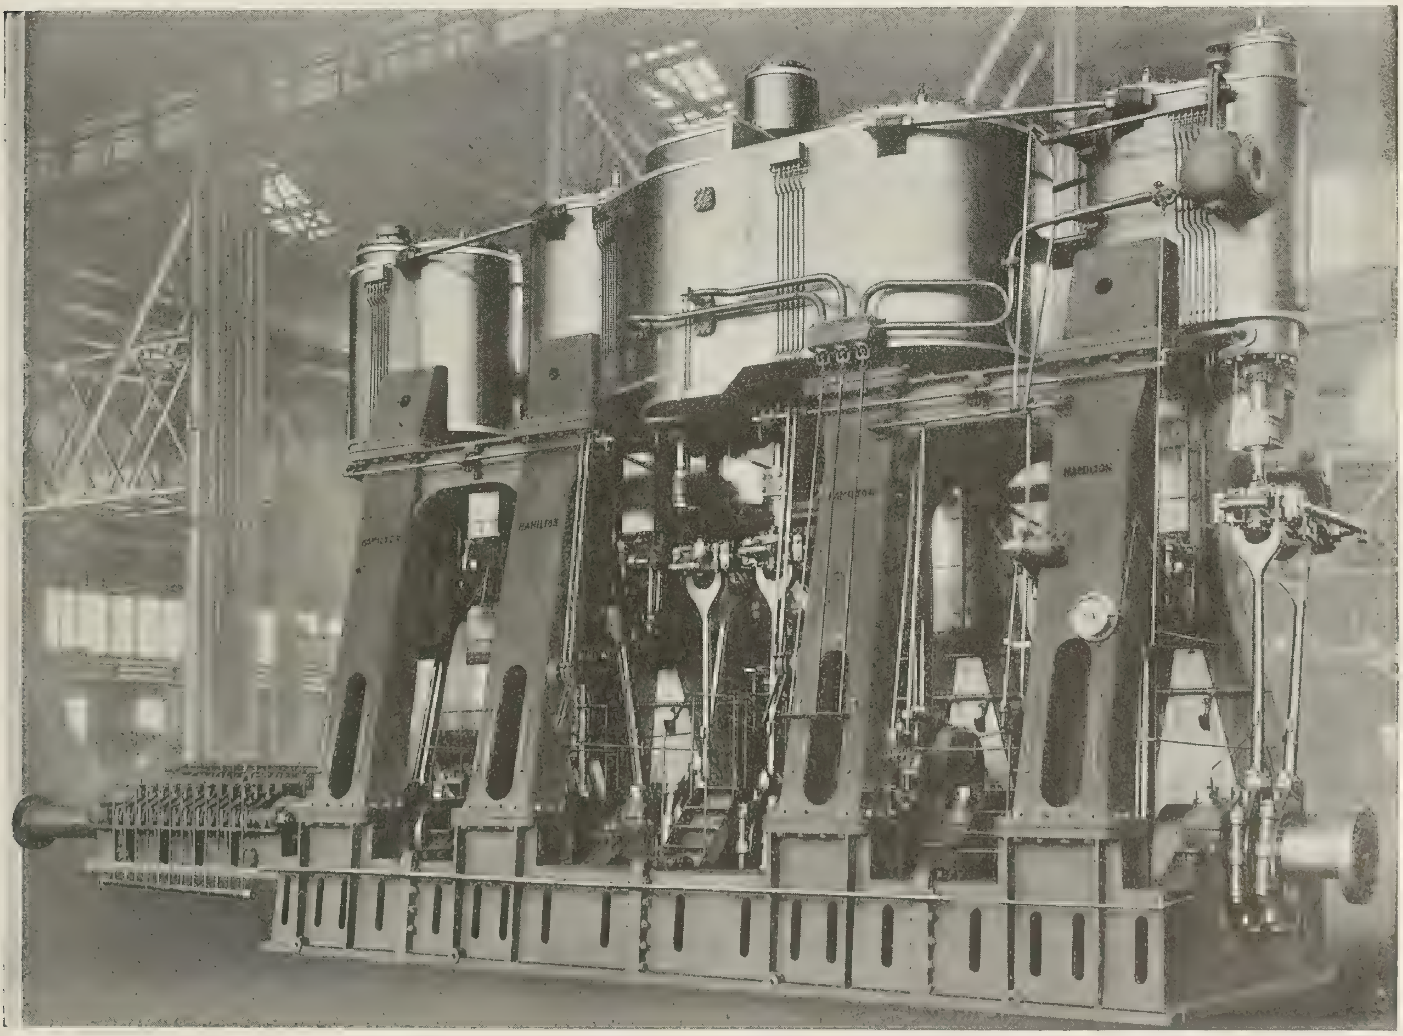
Main Engine

The cylinders of the main engine are 27½ inches, 40 inches, 59 inches and 86 inches diameter by 54 inches stroke. With a boiler pressure of 220 pounds per square inch the engine develops 4,200 indicated horsepower at 75 revolutions per minute.

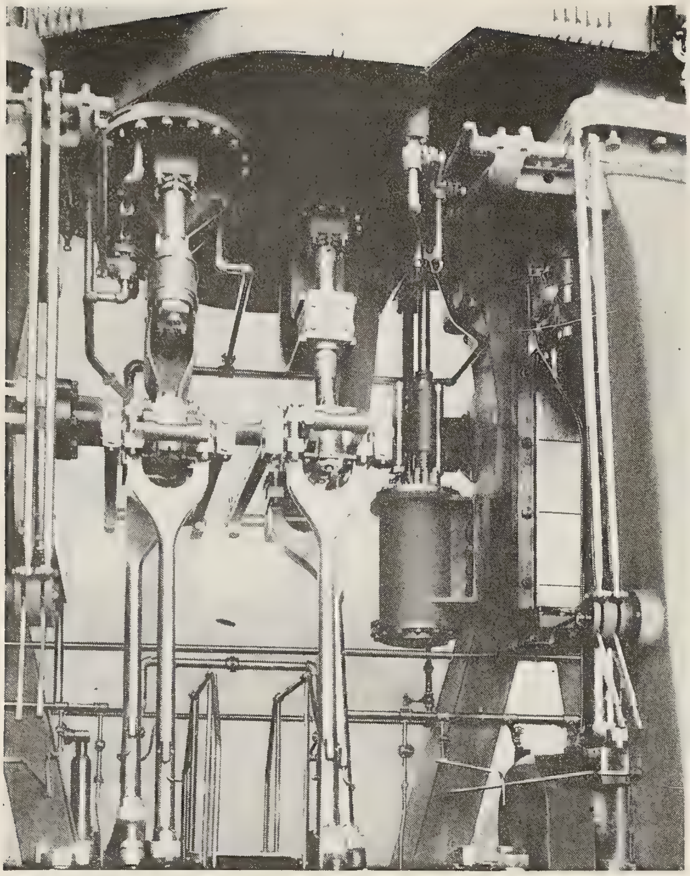
The arrangement of the cylinders from forward to aft is as follows: High pressure, low pressure, second intermediate and first intermediate. The cranks are balanced on the Yarrow-Schlick-Tweedy system offsetting the angles from the usual 90 degrees. This arrangement of the cylinders simplifies the receiver piping, reducing condensation to a minimum.

The high pressure, first and second intermediate cylinders are fitted with piston valves, the low pressure cylinder with a balanced slide valve. All piston valves are fitted with plain balance pistons on top and the slide valve with a Lovekin balance piston to counteract the unbalanced weight and inertia of the valve gear parts. The valves take steam as follows: High pressure, first and second intermediate inside and low pressure outside.

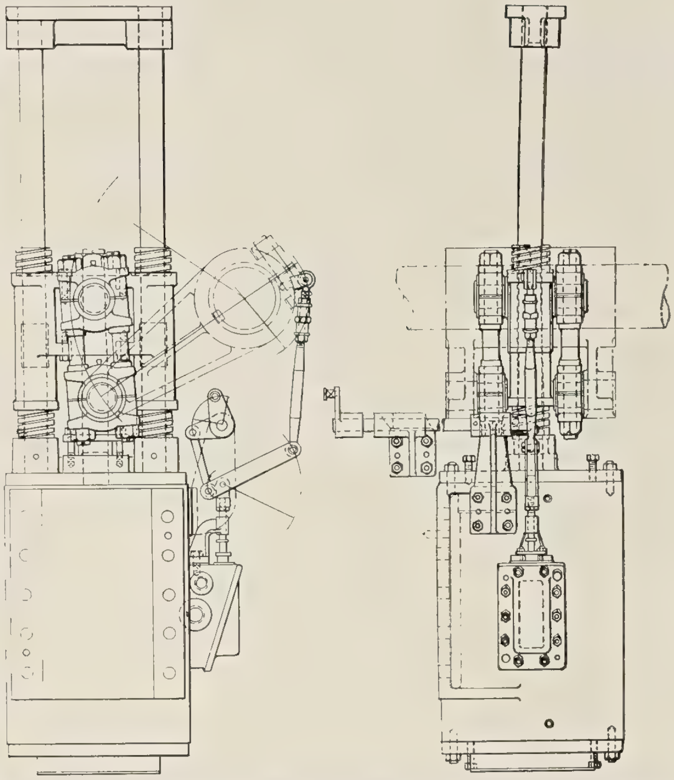
The pistons for the high pressure and first intermediate cylinders are made of cast iron and for the second intermediate and low pressure cylinders of cast iron. The low and second intermediate cylinders are bolted together with the



Main Engine of the Tamaihua Erected in the Builders' Shop



Arrangement of Reversing Engine



Front and Side Elevations of Reversing Engine, Showing Double Link Arrangement

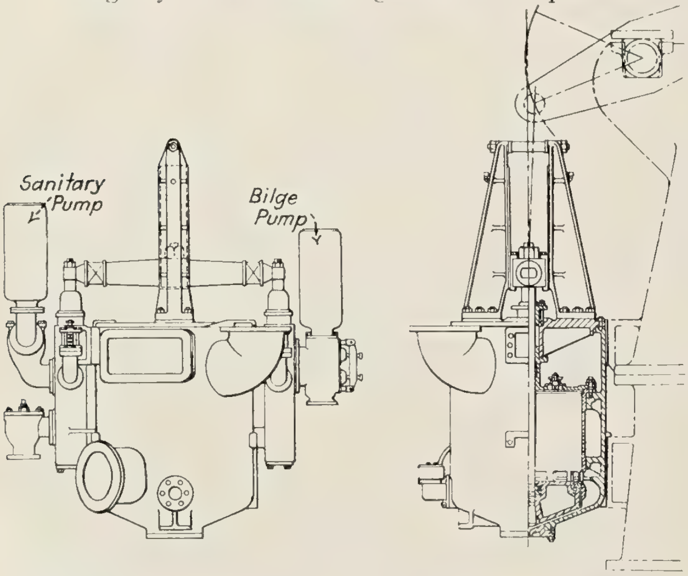
high pressure and first intermediate at either end and held by tie rods. This arrangement gives interchangeability to the crank shaft section, and eliminates outside receiver piping between the second intermediate and low pressure cylinders. The high pressure and first intermediate cylinder receiver pipes are made of copper fitted with expansion joints, which are provided with drain pockets for removing condensation.

The housings are box shaped, of cast iron, and arranged independent for each cylinder. The flanges for bolting to the bedplate and cylinders are liberally proportioned. Where the cylinders are independent, such as the high pressure and first intermediate, the housings are bolted together fore and aft for rigidity. The crosshead guides are independent and bolted to the face of the housings; they are provided with water circulation. The bedplate is made of cast iron in four sections bolted together. Cross girders heavily ribbed provide recesses for the main bearings. The bottom of the bedplate is flat for bolting to the ship structure.

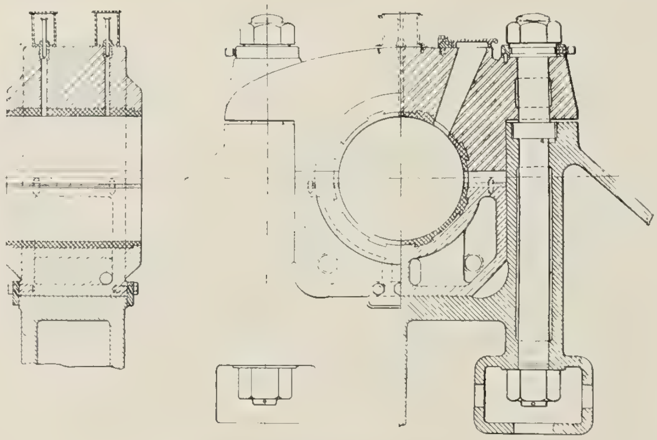
The air and bilge pumps are bolted to the second intermediate back housing and bedplate and are driven through a beam from the crosshead. The reverse engine, of the single ram type, is located on the aft side of the low pressure back housing. The turning engine, of the double cylinder type, is bolted to the forward side of the first intermediate back housing. The thrust is of the horseshoe type with bearings at each end; it rests on a separate casting, forming a foundation in line with the bedplate.

Construction Details

The crosshead construction is of the double slipper type with babbitted cast iron slippers bolted to the crosshead, the go-ahead side being on the back housing. The connecting rods are of the forked type with cast steel babbitted boxes on the crank end and bronze babbitted boxes for the crosshead



Arrangement of Pumps Attached to Main Engine, Showing Half Section of Air Pump



Details of Main Bearings

end, the usual provisions being made for providing taking up wear in all bearings.

The main bearing construction consists of a lower bronze babbitted box with cast steel babbitted cap, both fitted snugly into a recess on the bedplate. The lower box is cored for water circulation.

The crank shaft is built up in sections with the crank pins and shaft section shrunk onto the forged webs. The shaft is made in four interchangeable sections held together by reamed bolts.

Valve Gear

The valve gear is of the Stephenson link type. The eccentric sheaves are of cast iron in halves keyed to the shaft and held together by fitted bolts. The eccentric straps are of cast steel with babbitted face and fitted with shims for taking up wear. The eccentric rods have bronze boxes for attachment to the links. For "going ahead" the eccentric rods are arranged for "crossed rods," using long drag rods for connecting the links with the reverse shaft. The reverse shaft is located on the back of the engine and supported by babbitted bearings to the housings.

The reverse levers are of cast steel keyed to the shaft and fitted with slotted arrangement for adjusting cut-offs. The valve stems for the second intermediate cylinder, having two valves, are connected by a steel casting crosshead fitted with bronze liners operating on guides bolted to the cylinder.

Reverse Engine

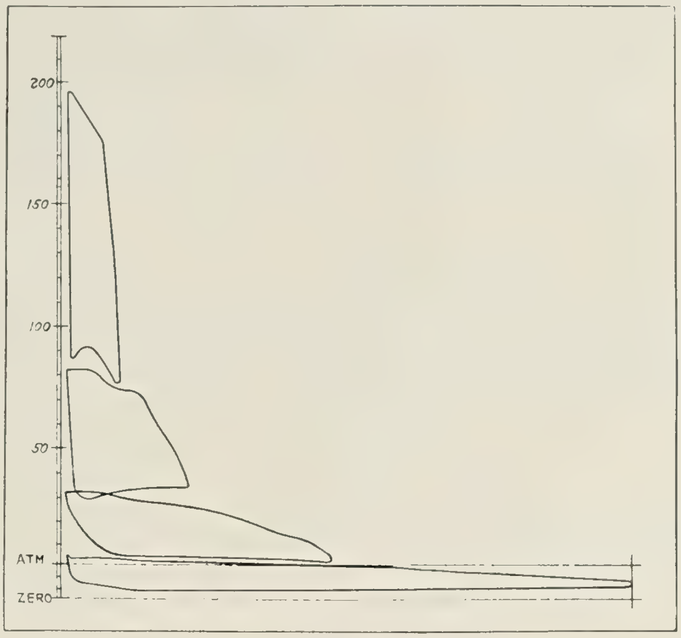
The reverse engine is of the single steam ram type, consisting of a steam cylinder operating an arm keyed to the reverse shaft.

The engine is bolted to the low pressure back housing. In order to avoid the usual long overhang, a scheme of bringing the cylinder close to the housing was evolved by a double link arrangement, and to absorb the extra thrust due to the short links a double guide bar was used. The follow up gear operating the slide valve is connected with the handling gear.

Attached Auxiliaries

The turning engine is of the double cylinder type fitted with Stephenson reverse links. It operates the main shaft through a double set of worm gearing. The disengaging is done by moving the worm out of gear with the wheel on the main shaft.

The air pump is of the Edwards single acting type driven from the main crosshead through beams. The pump body is of cast iron with removable bronze liner and cast iron bucket



Combined Indicator Diagrams

with bronze follower. The valve deck is of bronze with valves of excelsior fibre. The valves are accessible through an inspection door on the side of the pump body. The bucket rod of steel is attached to a crosshead which is guided by vertical brackets bolted to the pump cover.

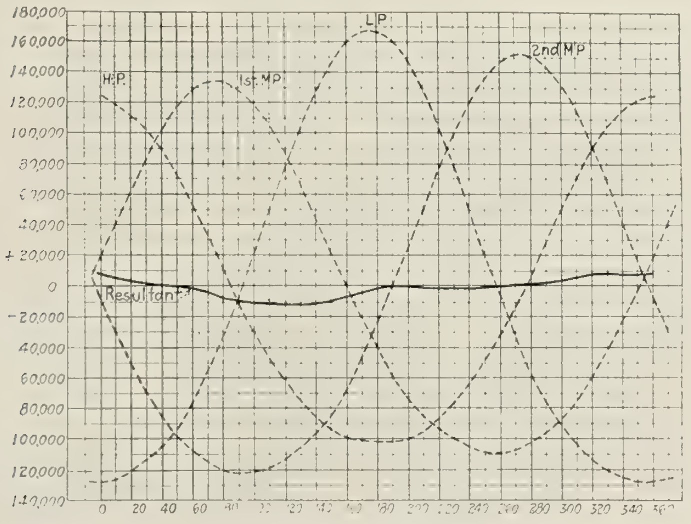
The bilge and sanitary pumps are bolted to the air pump, and the plungers are attached to the air pump crosshead. The bilge pump is fitted with leather clap valves and the sanitary pump with rubber valves. Air chambers and relief valves are provided as required for smooth operation and insurance against excessive pressures.

Handling and Operating Gears

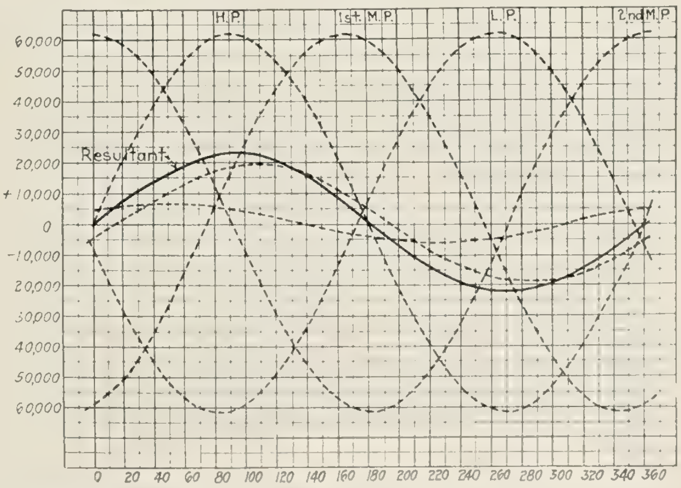
The throttle valve is of the double beat balanced type fitted with Monel metal seats. For quick control a butterfly valve is placed in the valve body close to the high pressure cylinder.

The steam chests of all cylinders are connected with the throttle for live steam connections. Operating levers for the throttle, reverse and drains are located on the starboard side and centralized around the low pressure housing within easy reach of the operator.

The oil cups for reciprocating parts are located on the front side of the cylinders and connected to the proper bearings



Vertical Inertia Forces of Cylinder and Valve Gear Rotating and Reciprocating Parts



Horizontal Forces of Cylinder and Valve Gear Rotating Parts

through pipes. Small bearings are provided with cups for hand oiling and the main bearings with wick oilers

Water service from the sea is supplied for the shaft bearings, eccentrics and thrust shoes. The guides are water cooled, by connection to the sanitary system. Ample provision is made for protecting the operators against the moving parts by guards, rails and covers, and steps are fitted over the shaft at convenient places. The eccentrics operate in oil-tight pans. Relief valves are fitted to the top and bottom of all cylinders and on all valve chests. There is also a system of drain piping attached to the cylinders and chests connected to the condenser or feed water system. The drain valves are operated from the lower grating.

Balancing of the Engine

The engine was designed with the view of obtaining the best balance, without any sacrifice in weight or strength. The cranks were arranged on the Yarrow-Schlick-Tweedy system.

The curves (page 311) show the effect of both vertical and horizontal forces due to cylinder and valve gear reciprocating and rotating parts. The resultants are well within practical limits for smooth operation.

Detail Dimensions

The principal dimensions of detail parts of the engine are as follows:

Diameter of crank shaft	16 inches
Diameter and length of main bearings	16 by 17 inches
Diameter and length of crank pin	16¼ by 16½ inches
Diameter and length of crosshead pin	8 by 9 inches
Length between centers of connecting rod	120 inches
Diameter of connecting rod—top and bottom	7 inches—8 inches
Length and width of crosshead slipper	30 by 18 inches
Diameter of high pressure piston valve—top and bottom	12 inches—11½ inches
Diameter of first intermediate pressure piston valve—top and bottom	21 inches—20½ inches
Diameter of second intermediate pressure piston valve—top and bottom (2)	21 inches—20½ inches
Diameter of piston rod	7½ inches
Diameter of valve stem stuffing box—guides	4½ inches—5 inches
Lineal clearance of cylinders—top and bottom	½ inch—⅝ inch
Diameter of steam pipe	10 inches
Diameter of exhaust pipe	30 inches
Diameter and length of link block pin	5 by 5½ inches
Diameter and width of eccentrics	33 by 5¼ inches
Diameter and length of eccentric rod pin	4 by 4 inches
Diameter of eccentric rods—top and bottom	3⅝ inches—4⅝ inches
Diameter and length of drag link pin	3 by 3½ inches
Width and height of link bar	2 by 6½ inches
Diameter and stroke of reverse engine	16 by 25 inches
Diameter of reverse shaft	8 inches
Diameter and stroke of turning engine, double	6 by 6 by 6 inches
Diameter of thrust shaft	16 inches
Diameter and number of collars of thrust shaft	27 inches—12
Thickness of thrust collars	2½ inches
Diameter and number of coupling bolts	2¾ inches—12

Trial Trip

On September 19, 1921, the trial trip was made and every part of the machinery worked successfully. A speed of 11.32 knots was obtained on a 28-foot draft with an indicated horsepower of 3,615 at 70 revolutions per minute.

Observations during the trial trip were as follows:

Steam boiler pressure	218 pounds per square inch
Pressure in high pressure steam chest	192 pounds per square inch
Pressure in first intermediate pressure receiver	86 pounds per square inch
Pressure in second intermediate pressure receiver	31.5 pounds per square inch
Pressure in low pressure receiver	5 pounds per square inch
Vacuum	24 inches
Temperature of feed water, inlet	122 degrees
Temperature of feed water, outlet	194 degrees
Back pressure in heater	5 pounds per square inch
Temperature of inlet sea water	55 degrees
Temperature of outlet sea water from condenser	118 degrees
Temperature of condenser exhaust	132 degrees
Temperature fuel oil to heater	62 degrees
Temperature fuel oil from heater	202 degrees
Pressure of fuel oil	150 pounds per square inch
Pressure forced draft	1¼ inches
Pressure forced draft at furnace	0.4 inch
Temperature of engine room	81 degrees
Temperature of boiler room	88 degrees

During the trial a check was made on the fuel consumption, which showed 11.8 barrels of oil per hour which is equivalent to 0.94 pound per indicated horsepower hour.

The builders' guarantees both as to speed and economy were fulfilled by liberal margins.

Maiden Voyage

The *Tamiahua* left San Francisco on September 29, 1921, on its maiden voyage through the Panama Canal to New Orleans. Great interest had been evidenced in this ship as it is the largest merchant vessel ever built on the Pacific Coast of the United States or in fact on the west coast of the Western Hemisphere. It also has the largest deadweight tonnage of any ship that ever sailed out of the port of San Francisco or into the ports of New Orleans and Galveston.

The voyage to Panama was uneventful as everything worked smoothly, the engine operating without vibration or any sign of heating of the bearings. The ship was water ballasted to 18 feet, mean draft, and maintained an average speed of 10½ knots, with the engine developing 2,725 indicated horsepower at 61.9 revolutions per minute. Sounding of the tanks indicated an oil consumption of 0.927 pound per indicated horsepower hour, with all oil consumed by the engine and auxiliaries charged to the main engine horsepower. Allowing for auxiliaries this gives 0.86 pound of oil per indicated horsepower hour used by the main engine alone.

From Panama the ship proceeded to New Orleans under an average speed of 11 knots with the engine developing 3,100 indicated horsepower at 65.9 revolutions per minute. The fuel consumption from sounding indicated 0.96 pound of oil per indicated horsepower hour with all oil used charged to the main engine or 0.89 pound deducting for auxiliaries. The oil used was 18.9 Baume gravity.

The vessel recently made a voyage from Port Lobos, Mexico, to Philadelphia and delivered at the latter port 115,092 barrels of 20 gravity oil. The distance covered on the voyage was 2,010 nautical miles with the main engine averaging 65 revolutions per minute and indicating 3,255 horsepower, including auxiliaries. The fuel consumption per indicated horsepower hour, including auxiliaries, amounted to 0.948 pound. The oil used was Mexican crude of 12 Baume gravity with a caloric value of 17,400 British thermal units. The total oil consumption per day was 33.07 tons and the average speed 10.63 knots.

Shipping Board to Open Freight Offices in Middle West.—In accordance with plans which have been under consideration for some time, the Shipping Board Emergency Fleet Corporation will open shortly a series of freight offices at Cincinnati, Memphis, Kansas City, Chicago, Detroit and Minneapolis, which will report to a manager of interior offices with headquarters in Washington. The managers of these interior offices are to work for the development of the American merchant marine by keeping in touch with local business organizations and with possible shipments, but will not themselves pick cargoes.

Twin Screw American Motorship William Penn

William Penn Completes Voyage Around the World

Motorship Demonstrates Reliability of Diesel Engine—Striking Fuel Economies Recorded for Main and Auxiliary Machinery

THE *William Penn* has the distinction of being the first large American motorship suitable for the deep sea cargo trade. She is owned by the Shipping Board and operated by the Barber Steamship Lines.

On March 19 she completed her maiden voyage around the world of 28,500 miles, and has completely demonstrated the reliability of the Diesel drive and the great economic superiority of the motorship over the steam-driven vessel.

On her arrival back in New York, the propelling machinery was found to be in perfect condition, with no expenditures whatsoever required for repairs. The exhaust and inlet valves of the main engines were changed only once which was at the middle of the voyage. All work on the main engines, which was of a routine nature, was done by the engineer personnel when in port, and all similar work on the auxiliary engines and machinery was done while under way, at sea. The auxiliary engines worked perfectly throughout the trip, and were run at times over 500 hours without stopping. There was no involuntary stopping of the vessel at any time throughout the voyage.

The motorship *William Penn* is 455 feet overall, 445 feet between perpendiculars, and 60 feet beam, with a designed draft of 28 feet, 4¾ inches, loaded, corresponding to 12,375 tons deadweight, and 17,100 tons displacement. The description of the machinery has been given previously and is the same as is being installed by the Cramp Company in the American-Hawaiian Steamship Company's motorships *California* and *Missourian.*

The main engines are six-cylinder, having a diameter of 29⅛ inches by 45¼ inches stroke, and originally designed for 4,500 indicated horsepower for the two engines, when turning at 115 revolutions per minute. Due to the full form of the *William Penn* the power was reduced by reducing the revolutions to 108, corresponding to the power of 4,200 indicated horsepower required for the 11.5 knots, and thus keeping the mean indicated pressure up to the same as originally designed.

There are, in addition, three auxiliary Diesel engines, each direct coupled to 65 kilowatt generators, for supplying current to the various electric driven engine room and deck machinery. At sea, one of the auxiliary engines was all that was required, with about a 55 kilowatt load carried, which included that required for coffee urns, electric hot plate, etc.

Starts Voyage Around the World

The *William Penn* left New York on September 3, 1921, stopping at Savannah to complete loading. The loading at New York consisted of case oil and barrelled grease, taken on at the Tidewater Oil Company's pier, and miscellaneous cargo put aboard at the pier of the Barber Steamship Lines, in Brooklyn. In Savannah, cotton and barrelled resin were loaded, the latter being placed on deck. She then sailed to the Far East, via Panama and Honolulu, at which latter place about 200 tons more fuel oil was put on to fill the tanks, so that it would not be necessary to purchase any additional oil at the higher prices prevailing in foreign ports.

The first stop to discharge cargo was at Yokohama, and the first severe storm was encountered between the 180 degree meridian and Yokohama, when it was necessary to slow down to prevent losing the deck cargo.

The vessel then proceeded in succession to Kobe, Shanghai, Foochow, Swatow, Hong Kong and Manila. At the latter named place unloading was completed and loading commenced for the return voyage. The next stop was at Cebu, Philippine Islands, and then passing between Celebes and Borneo, she stopped at Surabaya, Java, where Christmas was spent, 8 degrees below the equator. The next port was Singapore, Straits Settlements, where loading was completed for the return trip. The next stop was at Suez. After passing through the Suez Canal, she arrived at Port Said, where a small amount of cargo was taken out. The remainder of the cargo was discharged in turn at Marseilles, London, Rotterdam and Liverpool. From the latter place the vessel sailed on March 6 for New York, in ballast, arriving on the afternoon of the 19th, after having experienced some very severe gales in the North Atlantic, the wind at times attaining a velocity of 110 miles per hour.

On the return trip the vessel was not fully loaded, although the cargo was of very bulky nature, consisting of hemp, copra, rattans, tapioca, coffee, etc.

The total time required for the voyage, counting 24 hours to the day, was 197 days. The total number of days in port was 86, and the total time at sea was 108 days. About 3 days were taken up in passing through the two canals at reduced speed, up rivers, etc., from pilot boats to piers, and standbys at pilot boats, etc.

Fuel Consumption

The mean sea speed from New York to London was 11.01 knots, with a mean consumption of 13.06 tons per diem, (exclusive of donkey boiler). From Liverpool to New York, in ballast, the speed was reduced, due to the ship being in light condition, and to the very severe storms encountered, as previously mentioned, the vessel averaging 8.9 knots, with a mean consumption of 13.15 tons, (exclusive of donkey boiler).

The best speed was made the last day of her voyage, with 12.8 knots, and the main engines developing 4,700 indicated horsepower, thus proving that Diesel engines do not fall off in power at the finish of a long run, as is usual with the steam plant. Compression cards were taken at this time, which showed that compression was normal in all cylinders.

The longest non-stop run was from Singapore to Suez, or 4,943 nautical miles, taking nearly eighteen days, with a mean sea speed of 11.48 knots, and mean total consumption of main and auxiliary engines of 13.41 tons per day. The consumption per indicated horsepower, main engines only, and all purposes, was 0.3025 pound. The mean indicated horsepower taken when leaving Singapore was 4,130 and revolutions per minute 107.9, on a draft of 21 feet 8 inches.

On leaving Savannah the draft was 26 feet 5 inches and the mean sea speed from Savannah to Panama was 11.6 knots, with a consumption per 24 hours of 13.81 tons, and a consumption per indicated horsepower, main engines, all purposes, of 0.3055 pound.

Consumption for Auxiliaries

In port, when loading or unloading, with two or three auxiliary engines in operation during the day, and one engine running for the 24 hours, the consumption for the auxiliary engines was about 150 gallons per day, or 0.48 ton, which is from one-tenth to one-twentieth that for an equivalent steamer. When one engine was operated for the 24 hours, without winches in operation (as over holidays), the consumption was about 110 gallons per day. The consumption of the one auxiliary engine at sea was 120 gallons, or 0.36 ton. The donkey boiler takes from 160 to 170 gallons per day, or 0.52 to 0.55 ton, when in use.

The total consumption for the voyage was 1,475 tons. It is estimated for a steamer the consumption would have been 4,800 tons for the same trip, and it would have been necessary to have purchased 3,000 tons of oil abroad. It is figured that the motorship saved in cost of fuel alone from $60,000 to $70,000. On the outward voyage the deep tank was available for cargo, giving about 5 percent greater carrying capacity than that of the equivalent sister ships. The lowest fuel consumption recorded was from Honolulu to Yokohama, with 0.29 pound of oil per indicated horsepower, main engines, all purposes.

The lubricating oil required when at sea, for the whole plant, including main engines and auxiliary engines, averaged 15 gallons per day, for the voyage.

Considerable bad weather was encountered during the voyage, due to the time of the year. In addition to the storm in the Northern Pacific, after passing the 180th meridian, the *Penn* passed through a typhoon on the way from Hong Kong to Manila, and met very heavy weather and head winds for four days from Port Said to Marseilles. Of the total of 108 days at sea, 24 were stormy.

The *William Penn* sailed on April 22 for the Far East again, carrying chiefly heavy or deadweight cargo, consisting mostly of structural steel, and with the vessel loaded down to the full draft marks. She is able to carry with this class of cargo about 1,000 tons more than an equivalent steamer, representing the additional fuel and fresh water necessary to be carried by the steamer. Accordingly a much better showing should be made over the equivalent steamer on the second voyage.

Several Sister Steamships Laid Up

There are several sister ships equipped with either steam turbines or reciprocating engines, but which have been laid up for the past year or more, due to their inability to run at a profit.

A comparison with the electric driven ship *Eclipse* is in order, but due to incomplete data available for the electrically operated ship a strict comparison is impracticable. The *Eclipse* from various voyages is reported to burn from 32 to 40 tons per day from bar to bar, depending on whether 19 or 24 nozzles on the turbines are open, and corresponding to speeds from about 9 to 10 knots. This works out at about 14.9 tons per 100 miles. The consumption per 100 miles for the motorship *William Penn* from bar to bar works out at 4.87 tons from Singapore to Suez, and 4.94 tons from New York to London. The *William Penn* burns only a small fraction of that of the *Eclipse* in port but which does not appear in the above comparison.

	M/S Wm. Penn	S/S Eclipse
Length between perpendiculars, feet	445	440
Beam, feet	60	56
Depth to shelter deck, feet	36.67	38
Draft, loaded, feet	28.39	28.58
Displacement, loaded, tons	17,100	15,700
Deadweight, tons	12,375	11,867
Cargo, cubic feet, grain	627,830	589,355
Cargo, cubic feet, bales	593,910	552,969
Designed speed, knots	11.5	11
Designed revolutions per minute	108	100
Designed power	4,200IHP	3,000SHP

It will be seen from the above that the hull conditions are much more favorable for the *Eclipse* than for the *William Penn,* due to smaller displacement and finer lines of the former. The *William Penn* is being operated very close to her limiting speed, while the *Eclipse* is considerably under hers. With the *William Penn's* engines in the *Eclipse's* hull a better showing would have been made for the motorship.

Although America has been backward compared with other countries, in adopting the large motorship for the deep sea trade, it is hoped that the *William Penn* has showed the way and that there will soon be laid down a large number of motorships, which are so vital in the maintaining of the American flag on the sea.

The American-Hawaiian Company will soon have in commission two vessels of similar size to the *William Penn,* namely, the motorships *Californian* and *Missourian.* Due to their finer lines they should make a half knot better speed than the *William Penn* with their main engines developing their normal rated indicated horsepower of 4,500.

Differential Between American and British Ships.—A ship of the *George Washington* type would cost in the United States about $9,500,000. She could be built in England for about $7,500,000 to $8,000,000. The American owner of an American built *George Washington* would therefore have to carry, during the life of the ship, an excess capital cost of $1,500,000 to $2,000,000 on which he would be paying probably $250,000 to $300,000 per year more than a British owner of a similar ship. The payroll of this ship would be not less than $450,000 per year, and would involve a wage differential of nearly $100,000. The higher cost of repairs and of the American administrative staff would add to this another $25,000 making a total annual differential against this ship of approximately $400,000.

Electric Auxiliaries on Merchant Ships*

Motors for Deck and Engine Room Auxiliaries — Direct vs. Alternating Current—Wiring and Installation—Operation

By Edgar D. Dickinson†

BECAUSE electricity makes possible many reductions in the cost of operation and at the same time enhances the earning power of a ship, it is being used to an ever-increasing extent for driving the machinery on ships. On highly efficient new ships, especially motorships, practically all the auxiliaries are driven by electric motors. In the motorship Diesel engines are employed to drive the generators. On a steamship, however, the most generally accepted practice is to install turbine-driven generator sets for auxiliary power.

Auxiliary machinery on ships can be readily subdivided into two broad types: (*a*) For deck use; (*b*) for below-deck use. The motors most suitable are enclosed, weather-proof for above deck, and ventilated for below deck.

Deck Machinery

Electric deck machinery has been developed along two fundamentally distinct lines: one in which the motor is mechanically geared to the drums, and the other where some form of hydraulic speed reducing gear is fitted between motor and drum. The latter class seems to have found considerable favor abroad, where certain well-known manufacturers have developed winches, using either the Williams-Jenney or Hele-Shaw hydraulic power transmission. Electric hydraulic power transmission is particularly well adapted for steering gear work and has been developed in this country. For general winch service the hydraulic pump and motor are excessively costly.

For gear winches the series motor or compound-wound with very small amount of shunt winding is the most desirable.

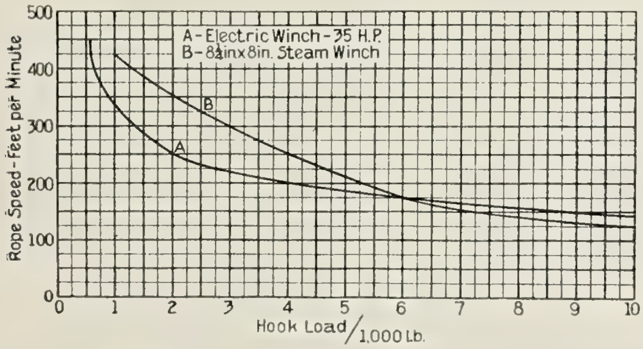


Fig. 1.—Characteristic Curves of Electric and Steam Winches

Fig. 1 shows how the natural characteristics of the series motor make it most suitable for winch service. It is found necessary to throttle the steam winch at light loads to reduce the speed. In practice, therefore, it approaches more nearly the speed of the electric winch. Many winches are fitted with winch heads. When handling cargo with these instead of the drum the revolutions per minute will run up somewhat. However, the winch head being of smaller diameter than the drum, it is generally found that the rope speed on the winch head will be about right.

For all service using hydraulic gear, constant-speed motors are used, either alternating-current or direct-current.

Of all the electric apparatus aboard a ship the winch is subject to the most abuse. Everything about it, therefore, should be designed, manufactured and installed in the most substantial and workmanlike manner.

Specifications for Electric Deck Machinery

Specifications for electric deck machinery should cover the following:

1. Insulation should be as highly moisture-resisting as it is possible to get by the use and treatment of the best materials. This applies not only to windings but to all bushings, brush holder collars, etc., which, if hygroscopic, are liable to result in grounds.

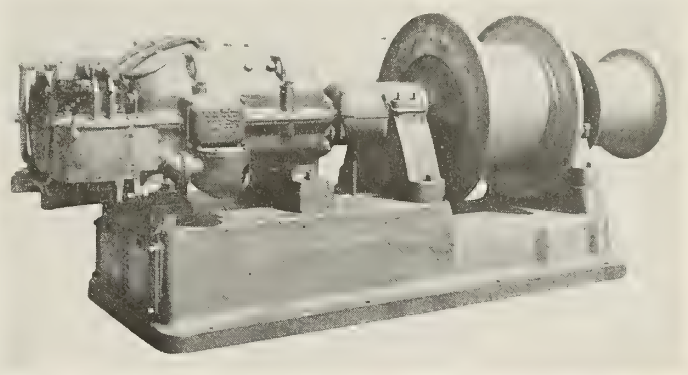

Fig. 2.—New Type of Electric Cargo Winch Having the Reduction Gear Inside the Drum

2. Motor frames should be thoroughly cleaned and painted on the inside to prevent, as far as possible, scale forming by corrosion.
3. Covers for inspection openings should preferably be hinged and arranged so as to clamp tightly. On all apparatus, motors, resistor boxes, controllers, etc., if impracticable to hinge the covers they should be attached by swinging bolts. Cap screws or cap bolts should not be used, as they are liable to be dropped into the motor or left on deck and lost.
4. Bearings should be designed to prevent, as far as possible, ingress of water and egress of oil due to rolling of the ship.
5. All apparatus should be provided with some form of drain. It must be recognized that, while machinery may be built in the factory so watertight that it can be submerged, there is no assurance that this condition will exist after it has been once opened on deck. Further, any totally enclosed electrical apparatus is liable to breathe under varying temperatures which may result in an accumulation of moisture by condensation.

The cost of good electrically fitted machinery installed should be little, if any, more than that of high-grade steam machinery. The insulation in a marine motor must be moisture resisting to the maximum practical extent; otherwise, it should not be deemed proper for the service.

Fig. 2 shows a deck winch developed in this country, several of which type will shortly be installed on ships. This winch is a radical departure from the generally recognized designs using either spur or worm gearing.

Electric steering gears have been developed for mechanical

*Paper read before the Society of Naval Architects and Marine Engineers, New York, November 17, 1921.
†General Electric Company, Schenectady, N. Y.

control of the rudder. For these the service is extremely intermittent, operating from two to ten times per minute, which means that the motor would be started, stopped and reversed thousands of times during one voyage. Such gears require the installation of a motor of sufficient torque to swing the rudder to the extreme angle, whereas during most of the time a very small amount of power is required. This means loss in efficiency as the motor is operating nearly all the time very much underloaded.

For controlling the steering gear from the pilot house two electrical means are available—follow-up and nonfollow-up. The first entails considerably more wiring, a multiple switch in the wheel house, a more complicated control in the steering engine compartment, and has the disadvantage of moving the rudder step by step a definite number of degrees. By the nonfollow-up means the rudder can be moved by fractions of degrees in either direction; its use, however, calls for the installation of a rudder indicator in the wheel house. A device has been worked out to show positively the position of the rudder at any instant, using simple means already developed.

Special Deck Machinery

The following is a table of deck machinery which, with slight modification, would be applicable to ships of any tonnage between 8,000 and 10,000 tons deadweight. It should be borne in mind that the size of the cargo winches is based upon the best practice for general cargo and therefore does not vary greatly with the size of the ship. The number of winches, however, has to be modified to suit the number of hatches and derrick booms of the different ships.

	No. units	Assumed motor horsepower	Duty
Anchor windlass..	1	70	Very intermittent, severe. Often submerged. May be stalled in operation.
Cargo winches....	12	35	Intermittent. Fast cycle, severe duty. Sometimes submerged. Wide range in loads and speeds.
Steering gear.....	1	35	Seldom fully loaded. Severe intermittent duty with mechanical gear. Moderate continuous duty with hydraulic gear.

Types Developed (Electric Deck Machinery)

	Drive	Motor	Speed control
Anchor windlass and capstan....	Spur gear....	Reversing	Electric.
	Worm gear...	Reversing	Electric.
	Hydraulic ...	Constant speed.	Hydraulic.
Cargo winch...	Worm gear. Spur gear..	Reversing	Electric with electric brake (general use).
		Reversing	Electric with mechanical brake.
		Constant speed.	Mechanical brake and clutch (free drum winch).
		Constant speed.	Mechanical brake hoisting and lowering clutches.
		Constant speed.	Reverse gear and brake. No speed control (winch head only).
	Hydraulic ...	Constant speed.	Hydraulic.
Steering gear.....	Spur gear....	Reversing	Electric.
	Worm gear...	Reversing	Remote.
	Hydraulic ...	Constant speed.	Hydraulic.

Below-Deck Machinery

It should not be necessary to emphasize the importance of fitting equipment of proper design and of the highest grade material, particularly pumps vital to the operation of the ship and which must be relied upon to operate continuously day and night for weeks at a stretch.

The greater part of the electrical machinery below deck is naturally located in the engineroom. The following table gives a list of below-deck auxiliaries suitable for a cargo ship of about 8,000 to 10,000 deadweight tons and equipped with 2,500 to 3,000 shaft horsepower steam turbine. A motorship requires somewhat fewer auxiliaries, and slightly less power is necessary for driving them. Tankers require a number of motor-driven pumps for discharging the cargo. These may be installed either in a special pump room or arranged with the motors on deck with vertical shafts to the pumps below. It will be noted that in the list there are only five sizes of motors. That is with the intent of simplification and to reduce the number of spare parts to be carried. A study of particular cases may show that it is possible to satisfactorily arrange the engine-room equipment so as to have still fewer sizes.

Below-Deck Auxiliaries

	No. units	Assumed motor rating in horsepower	Duty
Propulsion:			
1. Circulating pump	1	40	Continuous at sea.
2. Boiler feed......	2	25	One continuous at sea.
3. Forced draft fan.	1	20	Continuous at sea.
4. Condensate	1	5	Continuous at sea.
5. Lubricating oil...	2	5	One continuous at sea.
6. Oil cooler water..	1	5	Continuous at sea.
7. Fuel oil.........	2	5	One continuous at sea.
8. Fuel oil trans....	1	5	Intermittent (assume 4 hours per day).
Service:			
9. Fire and bilge...	1	10	Intermittent (assume 6 hours per day).
10. General service..	1	10	Intermittent (assume 6 hours per day).
11. Sanitary	1	5	Intermittent (assume 12 hours per day).
12. Fresh water.....	1	5	Intermittent (assume 2 hours per day).
13. Refrigerating ...	2	5	One continuous at sea.
14. Evaporator	1	5	Intermittent (assume 3 hours per day).
15. Ballast	1	10	Intermittent (assume 4 hours per day).
16. Workshop	1	5	
17. Oil purifier......	1	5	
18. Galley	1	5	

Motors for these auxiliaries should be designed for continuous running, because, while certain pumps may be started and stopped frequently, the service cannot be considered intermittent.

In the engine room, and in fact even if placed in the lowest part of the ship, totally enclosed motors are not recommended. For continuous operation they would have to be excessively large. With the changes in the atmosphere that take place below the waterline, enclosed motors would be more liable to sweat and accumulate moisture internally than if well ventilated. In general, enclosed self-ventilated motors are recommended for the reason that they are often located in congested places where, if open, they would be

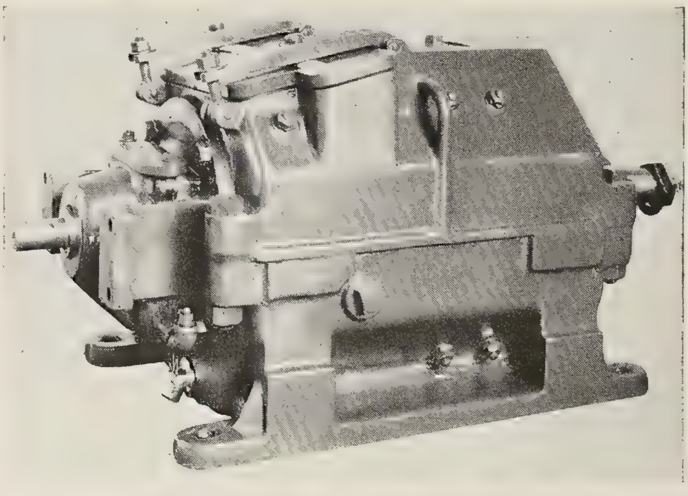

Fig. 3.—Direct Current Motor, Enclosed for Operating Deck Machinery

liable to mechanical injury and in addition would have to be protected from dripping water. However, as electrical machinery, when open, is more readily inspected and kept clean, it is not essential that the motors be enclosed if located, *e. g.*, on a gallery and properly protected from dripping water. Such motors should be screened to prevent rats eating the insulation. On tankers, if the cargo pump motors are of the direct current type and are located in a special pump room, they must be provided with some means of ventilation which will insure all explosive gases being driven off before the motors are started.

The motors in the engine room should be insulated with the same care and the castings as thoroughly cleaned and painted as the motors on deck. The insulation on all marine electrical apparatus should be made as highly moisture-resisting as possible.

As illustrating the adaptability of electrical apparatus, the writer recently saw a report from a chief engineer which stated that when the steam engines on his circulating pump and dry vacuum pump broke down he replaced them by two deck winch motors. The drive was so satisfactory that he intended to recommend that it be made permanent, and incidentally the ship burned 1½ tons of fuel oil per day less after the change.

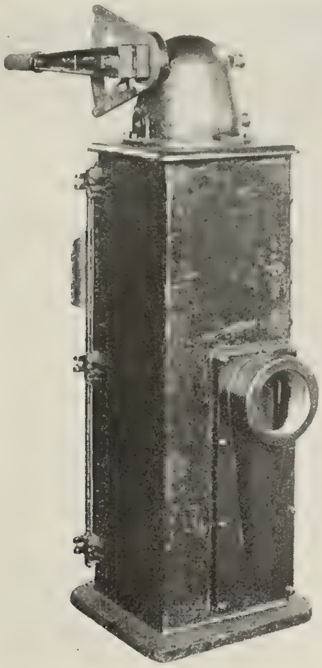

Fig. 4.—Controller for Deck Machinery Motors

Control

It would seem desirable that the means for starting and stopping each motor be located directly adjacent to it. Such starters are relatively inexpensive. They should be very substantial and moisture-resisting. Thin sheet iron should not be used, especially on any part of the construction which cannot be readily painted, as after a short time it is liable to rust and may be the cause of serious trouble.

On steamships the motors on the circulating pump, lubricating oil pump, boiler feed pump, hot well pump, balancer set or lighting motor-generator set, if any, and steering gear, should be fitted with starters, so that when power is restored after an interruption these particular motors will immediately start up automatically. The other motors can be restarted by the engineer at his convenience.

Generating Units

A study of the installations on a number of cargo ships of various tonnages indicates that on a steamship 150 kilowatts would give ample power for the deck machinery when in port and for the entire engine-room equipment when at sea. On a motorship about 75 kilowatts are necessary at sea. Therefore, on cargo ships of about 10,000 deadweight tons, two 150 kilowatt steam turbines or on the motorships three 75 kilowatt generator sets would give ample power with one unit for a standby at all times. The auxiliary power in many cases will be much greater than 150 kilowatts on refrigerator ships and on ships fitted in part for passenger service. The larger the amount of auxiliary power the greater the reason for highly efficient auxiliary turbines. Some studies have shown requirements for auxiliary power as great as 1,500 kilowatts.

Small steam turbines should be rugged and simple, as they will be classed as part of the propelling machinery and therefore vital to the safety of a ship. In sizes of 150 kilowatts and even smaller, gear reduction would be recommended, as the best direct current generator operation cannot be expected at the speed at which the turbine should run in order to get good economy. It is expected that these sets will be more substantial and rugged than sets of similar capacity for land service, where they are at all times readily accessible.

For the reason that on shipboard there is always possibility of scale or salt passing to the turbine from the boilers, it is preferable for the governor to control the speed by means of an oil Servo motor. All parts should be readily accessible. Even with the greatest care there is always liability that the lubrication may be momentarily interrupted, and as the bearings should be examined before the machinery is placed in service they should all be readily removable for inspection. An overspeed or emergency governor of the simplest and most reliable type should be fitted. Very specific and simple instructions should be issued to show the operating engineer the necessity of testing the governing mechanism periodically and assuring himself that it is in perfect operating condition.

The Most Suitable Electric Power

All references indicate that at the present time direct current is being generally adopted for auxiliary power on merchant ships. Some time ago there was considerable discussion as to the relative merits of alternating current and direct current. The following tabulation will show why direct current is being used to the greater extent:

Cargo Ships

Arguments For	*Arguments Against*
Direct Current	
1. Simple wiring.	1. Commutators require some attention.
2. Any speed control easily obtained.	
3. Equally suitable for continuous and intermittent duty.	
Alternating Current	
1. Lower cost of motors and generators.	1. Wiring more expensive
2. Absence of commutators.	2. Unsuitable for variable speeds necessitating hydraulic or other gear for winches and windlasses.

Tankers

Direct Current	
1. Simple wiring.	1. Commutators require some attention.
2. Equally suitable for continuous and intermittent duty.	2. Little necessity for variable speed motors. Special cases could be fitted with hydraulic or direct-current power furnished from small motor-generator set.
3. Speed of cargo pump can be varied to suit pressures and most efficient rate.	3. Special precautions must be taken to ventilate motors in tank room.
Alternating Current	
1. Lower cost of motors and generators.	1. Wiring more expensive.
2. Absence of commutators, particularly desirable in pump room.	2. Special motors necessary to change speed.
3. Cargo handled by constant speed pumps.	

It would seem that for cargo ships direct current can be used to the greatest advantage. On tankers this is not so apparent.

Except in the smaller ships, it is desirable to use not less than 230 volts. The lower voltage necessitates large or more expensive control; also the cost of wiring and switches is greater.

For lighting, the arguments seem to be in favor of 115 volts. This necessitates the installation of a small 115/230-volt motor-generator set. The use of incandescent lamps for 230 volts is not recommended.

Wiring and Installation

It is impossible to speak too forcibly on this subject. A

great deal of the criticism of electrical apparatus when thoroughly investigated has been found to be directly due to faulty, careless, slipshod methods of wiring and installation. Care and attention have been given to choosing apparatus, but the method of installation, the kind of wire, and many details of vital importance have been left to the wiremen's discretion with the inevitable result.

It is not the intention here to suggest that definite rules be laid down. Each engineer must work out his own particular problems. Certain underlying fundamentals, however, can generally be applied. The following are recommended:

That the wiring and distribution in the engine room be made as simple as possible, with relatively few circuits.

The switchboard should be largely a distribution panel designed with the idea of attaining maximum simplicity and occupying the least amount of engine-room space.

Circuits may be led from this distribution panel to different parts of the ship where they may be further subdivided,

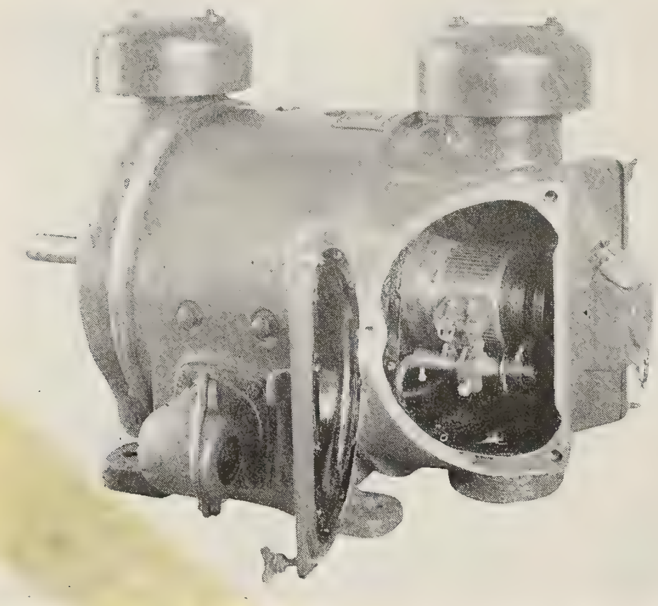

Fig. 5.—Direct Current Motor, Enclosed, Ventilated for Operating Below-Deck Machinery

as *e. g.*, five circuits for deck machinery, No. 1 to the steering engine, No. 2 to the after hatches, No. 3 to the forward hatches, No. 4 to anchor windlasses and forward capstans. No. 5 to after capstans. This will permit opening all the winch circuits when at sea and also allow for thorough inspection and try-out of the capstans, anchor windlass or steering engine when in port, even if cargo is being handled.

In the engine room a similar method may be applied, one circuit to the engine-room auxiliaries, port side, and another to the starboard side. By such simplification it will be possible to obtain low cost with maximum reliability.

Cables should not be run in conduits except, perhaps, for very short lengths where necessary for mechanical protection. Cables in the engine room should be run overhead. All cables should be thoroughly anchored so that the covering will not be chafed, due to vibration.

Operation

To study the relative merits of ships' auxiliaries, it is necessary to consider the part which they play in the economic operation of the ship.

It is not possible to make any exact general statement as to the proportions of the various items constituting the cost of operating merchant ships. They may, however, be listed as follows:

1. Fuel and lubricating oil at sea and in port.
2. Port charges including wharfage, lighterage, pilot fees, canal dues, stevedoring, tugboat charges, etc.
3. Salaries and subsistence.
4. Upkeep and repairs, deck department.
5. Upkeep and repairs, engine department.
6. Supplies, engine, deck and steward's departments.
7. Insurance
8. Loss and damage.

If we assume a 7,800 deadweight-ton ship fitted with 2,500 horsepower steam turbine on a schedule for coastwise service between New York and Seattle, stopping at San Pedro to load and discharge cargo and making four round trips per year, the charges might be approximately as follows:

Operating Disbursements

	Loaded both ways	Percentage	Loaded going, one-half loaded returning
1. Fuel	\$81,300	14.8	\$81,300
2. Port charge	290,420	52.9	211,020
3. Salaries	60,490	11.0	60,490
4. Repairs, deck	10,000	1.8	10,000
5. Repairs, engine	20,000	3.7	20,000
6. Supplies	20,250	3.7	20,250
7. Insurance	62,400	11.4	62,400
8. Loss and damage	3,650	.7	3,650
Total	\$548,510	100	\$469,110

Many of these would be affected by electrification of auxiliaries, and the net reduction would be very considerable.

1. *Fuel, etc.*—In the usual marine geared turbine installation with steam auxiliaries, the pressures generally carried are as follows:

	Gage
Boiler pressure	210 pounds.
Turbine bowl	200 pounds.
Auxiliary steam line	100 pounds.
Auxiliary exhaust	10 pounds.
Superheat	75 degrees F.

The auxiliary exhaust steam is used to heat the feed water, and that which is in excess of feed water heater requirements is by-passed to the main condenser.

Under full power, a fair operating average for this type of installation is as follows:

Steam Consumption per Hour:

	Pounds
Main turbine, 2,500 horsepower	28,875
Steam auxiliaries at sea	12,500
Total steam consumption	41,375

Steam per Shaft Horsepower Hour, all Purposes

$$\frac{41,375}{2,500} = 16.5 \text{ pounds.}$$

Boiler Evaporation.—With watertube boilers, Howden draft system, feed water delivered to boilers at 220 degrees, 210 pounds gage pressure and 75 degrees superheat, a conservative estimate of the actual evaporation per pound of fuel oil is taken at 13.5 pounds.

Fuel Consumption:

$$\text{Fuel per hour} = \frac{41,375}{13.5} = 3,065 \text{ pounds} = 9.6 \text{ barrels.}$$

Fuel per day, 73,560 pounds = 32.8 tons

Fuel in barrels per day 230

Fuel per Shaft Horsepower Hour:

$$\frac{3,065}{2,500} = 1.23 \text{ pounds.}$$

Fuel in Barrels, per Knot:

$$\text{Assuming a speed of 10.5 knots, } \frac{9.6}{10.5} = 0.915 \text{ barrel per knot.}$$

The economy to be gained through the application of electrically driven auxiliary machinery, in fuel consumption alone, may readily be seen from the following estimates:

Electric Auxiliaries

Superheat, 75 Degrees F.

Heating Feed Water.—The proposed method would be to extract sufficient steam from the turbine for feed-water heater requirements.

Steam Consumption, per Hour:

	Pounds
Main turbine, 2,500 horsepower	30,600
Turbine generator	2,640
Air ejector	1,000
Total	34,240

Note—3,600 pounds per hour steam will be extracted from main turbine at about 10 pounds gage to heat feed water.

Steam per Shaft Horsepower Hour, all Purposes:

$$\frac{34{,}240}{2{,}500} = 13.7 \text{ pounds}$$

Boiler Evaporation.—Estimated for comparative purposes at 13.5 pounds per pound of fuel. With the lesser quantity of steam to generate, however, the boiler efficiency would be improved in actual practice.

Fuel Consumption:

Fuel per hour, $\frac{34{,}240}{13.5} = 2{,}536$ pounds $= 7.9$ barrels.

Fuel per day, 60,864 pounds = 27 tons.
Fuel per day, in barrels = 189 barrels.

Fuel per Shaft Horsepower Hour:

$$\frac{2{,}536}{2{,}500} = 1.01 \text{ pounds.}$$

Fuel in Barrels per Knot:

Assuming a speed of 10.5 knots, $\frac{7.9}{10.5} = 0.75$ barrel per knot.

The application of high superheat, well within the limits of present-day design, and electric auxiliaries present a very interesting and high economic value in ship propulsion.

ELECTRICAL AUXILIARIES

Superheat, 200 *Degrees F.*

Steam Consumption, per Hour:

	Pounds
Main turbine, 2,500 horsepower	27,000
Turbine generator	2,400
Air ejector	1,000
	30,400

NOTE—3,000 pounds per hour steam will be extracted from main turbine at about 10 pounds gage to heat feed water.

Steam per Shaft Horsepower Hour, all Purposes:

$$\frac{30{,}400}{2{,}500} = 12.15 \text{ pounds.}$$

Boiler Evaporation.

Assumed at 13 pounds per pound of fuel.

Fuel Consumption:

Fuel per hour $= \frac{30{,}400}{13} = 2{,}340$ pounds $= 7.33$ barrels.

Fuel per day, 56,200 pounds = 25.1 tons.
Fuel in barrels per day = 176 barrels.

Fuel per Shaft Horsepower Hour:

$$\frac{2{,}340}{2{,}500} = 0.936 \text{ pound.}$$

Fuel in Barrels per Knot:

Assuming a speed of 10.5 knots, $\frac{7.33}{10.5} = 0.698$ barrel per knot.

These estimates show the saving in fuel consumption by the use of electric auxiliaries, as follows:

Saving in Fuel Consumption (at sea):

Steam auxiliaries, 230 barrels.
Electric auxiliaries, 189 barrels, 17.3 percent.
Electric auxiliaries, with 200 degrees F., 176 barrels, 23.5 percent.

Saving per Year:

208 days at sea, oil at $1.50 per barrel.
Electric auxiliaries, 8,320 barrels at $1.50 = $12,480.
Electric auxiliaries, with 200 degrees F. superheat, 11,250 barrels at $1.50 = $16,900.

In the estimate, an allowance was made of 40 barrels per day in port. With electric auxiliaries and economic engine-room machinery, it should be possible to reduce this by one-half.

157 days × 20 pounds × $1.50 = $4,710.

With a good system in the engine room, the lubricating oil required would be greatly reduced.

2. *Port Charges.*—In giving thoughtful consideration to improving the earning power of a ship, it will be recognized as essential to decrease its idle time, as certain charges are continuous, whereas the ship is actually earning money only when traveling between ports. When it is realized that the average cargo ship makes only about 36,000 miles per year and that at an average speed of 10 knots, which means that she is at sea only about 150 days out of a year, it is very evident that there is a big field for improvement.

Port charges estimated for the coastwise schedule mentioned above are as follows:

	New York	Colon	Los Angeles	San Francisco	Seattle	Total
(a) Wharfage	$7,800.00	....	$1,560	$3,120	$3,120	$15,600.00
(b) Lighterage	......	....	....	....	....	......
(c) Pilots' fees	202 56	....	200	250	....	652.56
(d) Stevedoring	7,800.00	....	1,560	3,120	3,120	15,600.00
(e) Tugboat charges	100.00	....	....	200	....	300.00
(f) Canal dues	......	$4,150	....	....	....	4,150.00
Total per trip						$36,302.56
Total per year (four round trips)						290,420.48

It will be evident that any means which will reduce the time a ship has to lie at the wharf loading or unloading cargo should lessen the two items, wharfage and stevedoring. The writer has been informed of specific cases where ships have been delayed at docks due to freezing of steam-deck machinery. He has also been informed of a specific case where with two similar ships loading and unloading the same kind of cargo at the same dock and with the same stevedore foreman, the electrically equipped ship loaded in very much less time. Another specific case was where a number of ships fitted with steam-deck machinery had to await the derrick to assist in loading heavy cargo, while a ship fitted with electric machinery was able to handle its own cargo and saved a number of days' delay.

Delays have been experienced with steam machinery due to low steam pressure. This may not be due to drop in boiler pressure but to loss in piping. With electric equipment there is always ample power available for the winches.

By the use of the most suitable electric machinery, it should be possible to reduce the item of port charges 10 percent. In the estimate given above this would mean approximately $30,000 per year saving.

3. *Salaries.*—In all probability the salaries would not be directly affected. In the larger ships and in those where there is a very large amount of auxiliary power it might be found desirable to increase the salary slightly for one of the positions, in order to secure a man with electrical experience.

4 and 5. *Upkeep and Repairs.*—Both of these items should be reduced. With properly designed electric machinery, the charges for repairs and maintenance would be less than with steam machinery. If compared with many existing ships, a 20 percent reduction would in all probability be a conservative estimate. If we only allow 10 percent, however, this would mean a saving of approximately $3,000 per year on the above estimate.

6. *Supplies.*—This item would not be appreciably affected in the deck department, but for the engine department there should be a material reduction. A saving of 10 percent might be expected, which would amount to $2,000 per year.

7. *Insurance.*—The assured reliability of proper electrical machinery in the engine room, along with the elimination of a large amount of piping carrying high pressure steam, should have a direct bearing on the insurance rate. Indirectly, by reducing the loss of steam it should be possible to maintain the water in the boilers in almost perfect condition. This should still further add to the safety of a ship. It would seem to be justifiable to expect that the insurance premiums can be decreased about 5 percent; this would mean a saving of approximately $3,000 per year.

8. *Loss and Damage.*—This item in all probability would not be affected.

The sum of the different gains mentioned above totals $55,190 per year. The amount of saving that can be shown by other estimates will naturally vary with conditions. In any estimates the possibility of making a substantial gain in the earning capacity in a ship is a real one. Having in mind certain ships, there is every reason to believe that the figures mentioned above might be increased.

One of the latest British combined cargo and passenger ships is equipped electrically and is fitted with over 100 motors driving auxiliary apparatus. Needless to say, the owners of new foreign ships are fitting them with electrically driven machinery only because they have satisfied themselves that it is profitable to do so. We engineers in this country should combine our efforts and avail ourselves of every opportunity to improve the efficiency of our merchant ships.

The Influence of Shape of Transverse Sections Upon the Resistance of Vessels of Moderate Speed*

By Professor Herbert C. Sadler† and Professor E. M. Bragg††

FROM time to time results of experiments on the influence of shape of bow and stern sections upon the resistance of ships' forms have been recorded, but usually these have referred to special cases, sometimes accompanied by other changes of form and generally for vessels of somewhat high speed.

Froude's original dictum of U-shaped sections forward and V-shaped aft still lingers in the minds of most designers as applicable to all forms at all speeds. Some years ago some experiments on models of full form were conducted in the experimental tank at the University of Michigan (see Vol. 17, Society of Naval Architects and Marine Engineers), in which it appeared that the V-shaped sections, both forward and aft, gave the better results.

The following investigation was therefore undertaken with the object of covering the field more fully, especially for the slower and moderate speed types.

The parent body plans and curve of sectional areas are shown in Fig. 1, and indicate the changes in type of sections used. They are based upon a vessel 425 feet between perpendiculars by 56 feet, with a normal load draft of 24 feet 9 inches, and a deep load of 27 feet 9 inches. The vessel has a cruiser stern and a length on the deep load line of 435 feet, this length forming the basis that was used for the spacing of sections.

The shape of the cruiser stern had to be modified slightly with different lengths of run for fairing purposes, but at the 24-foot 9-inch draft the change in length was negligible.

The various percentages of ends and middle bodies are given in terms of the length between perpendiculars. All the results have been reduced to a temperature of 65 degrees F.

In general, two parent forms were taken as follows:

1. A model with a fixed length of run and with "medium" type of stern sections.
2. A model with a fixed length of entrance and "medium" type of bow sections.

Each model was further modified in the following manner:

Fixed run 40.5 per cent L. B. P.	Five lengths of entrance from 23.7 percent to 48.5 percent L. B. P.	Each type with U, Medium, and V-shaped sections forward.
Fixed entrance 27 percent L. B. P.	Four lengths of run from 24.3 percent to 48.6 percent L. B. P.	Each type with U, Medium, and V-shaped sections aft.

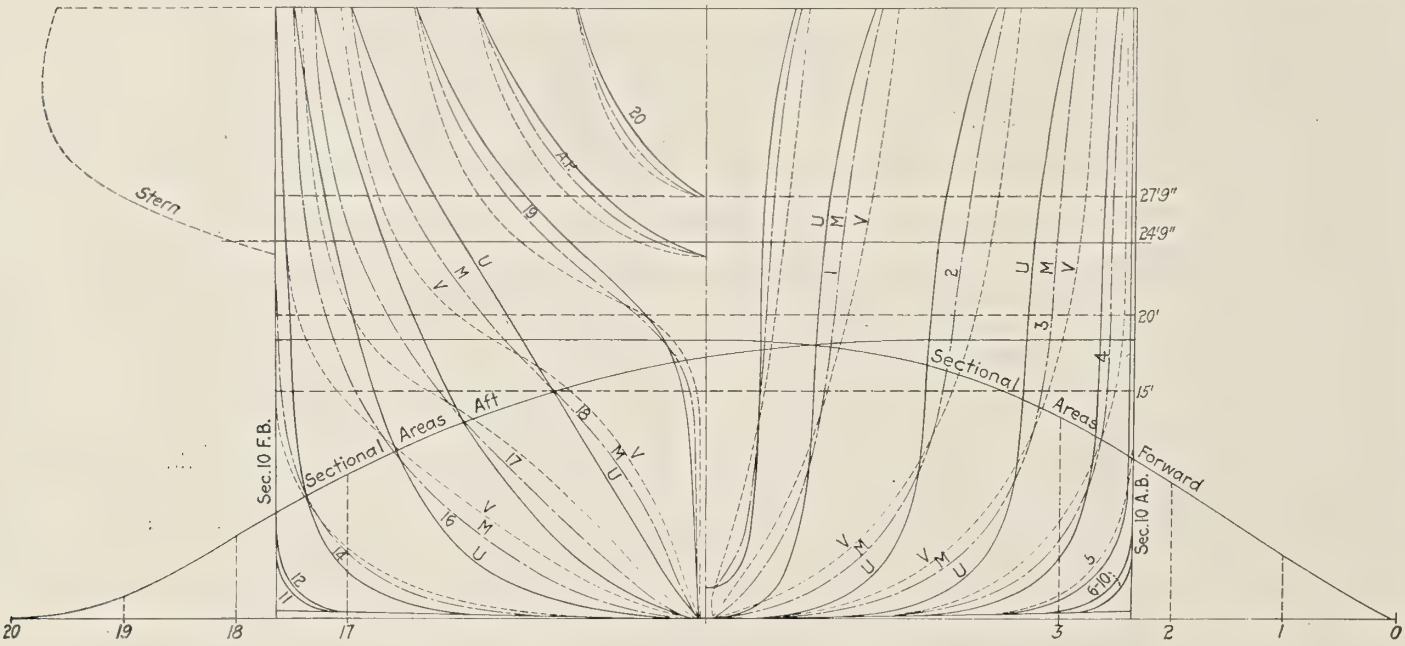

Fig. 1

The parent forms, with the above lengths of entrance and run, were selected from a former series of experiments covering some hundred types and appeared to be those that gave the best results from a resistance standpoint, for the range of speeds suitable for the present series of models. Each model was tested at four different drafts and consequently represents four types of vessels with varying ratios of beam to draft, and varying prismatic coefficients.

The particulars of the parent form are given in the following table, the prismatic coefficients being for the whole vessel, and a parallel middle body of 32.5 percent.

	Bow sections varying	*Stern sections varying*	*B/d*
15-foot draft	U, .734 M, .730 V, .727	.737 .728 .721	3.73
20-foot draft	U, .756 M, .754 V, .753	.757 .753 .750	2.8
24-foot 9-inch draft......	U, .772 M, .772 V, .772	.772 .772 .772	2.26
27-foot 9-inch draft......	U, .785 M, .786 V, .787	.783 .784 .785	2.02

*Paper read before the Society of Naval Architects and Marine Engineers, November, 1921.

†Professor of naval architecture, University of Michigan, Ann Arbor, Mich.
††Professor of naval architecture and marine enginerineg, University of Michigan.

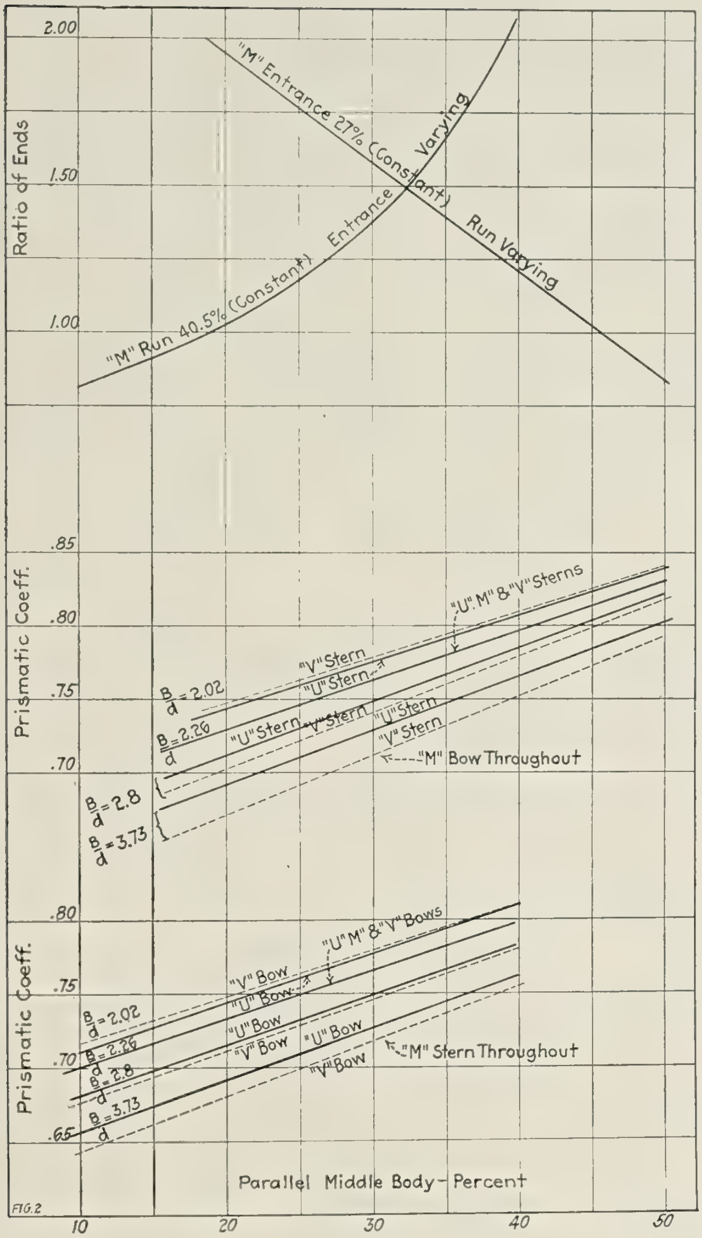

Fig. 2

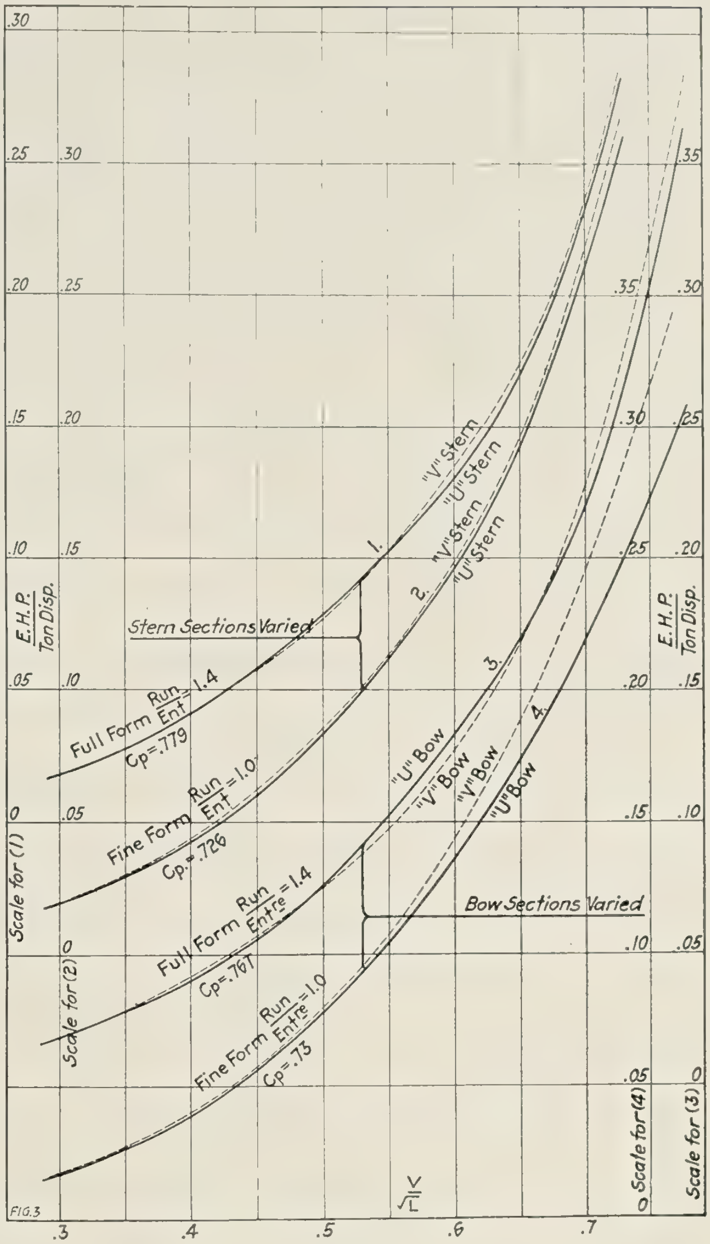

Fig. 3

For other variations of percentage of middle body and ends the change in prismatic coefficient is shown in Fig. 2.

Methods of Plotting Results

There has been some discussion in this and other countries as to the various methods used for recording the results of tank experiments. Here it has been customary to give the residuary resistance in pounds per ton of displacement on a speed-length ratio base. Abroad, the Froude constant system or **C** values, or a modification by Baker, or **P** values have been used. Arguments pro and con for each system can be made, but the deciding factor rests in the use to which the results are to be put. If for general comparative purposes in tank work, then the **C** values on a speed-length ratio base, or even **P** values, possess certain advantages. In other words, the "ideally best" vessel may be readily determined. If, however, the results are to be used by the practicing naval architects, it would seem that a somewhat more simple form would be preferable, especially as limiting conditions of design, and the necessity of arriving at the results of minor modifications quickly are the governing factors.

The following results have therefore been plotted in the form of effective horsepower per ton of displacement or $\frac{\text{EHP}}{\text{Tons}}$ upon a speed-length ratio or $\frac{V}{\sqrt{L}}$ base, and apply directly to a 425-foot ship.

They can be readily modified for any other length by multiplying by the square root of the length ratio up to a difference of 10 percent either way, and within the limits of, say, 2 or 3 percent either way may be taken as practically constant for a given speed-length ratio.

Another reason why there appears to be no particular necessity for having a system which will apply to all lengths of ships from the model up is that in practice the ratio of length to beam, and beam to draft will vary considerably in passing from a small to a large vessel, and therefore the results of any set of experiments must necessarily have a somewhat limited application, depending upon the relative sizes and types of vessels.

The ratio of horsepower to displacement is also one of the factors entering into the economy of vessels and hence in preliminary design work may have to be taken into account.

A discussion of the proposed method is given in the appendix.

In order to exaggerate certain features in the present paper so that the diagrams will show more clearly the effect of the

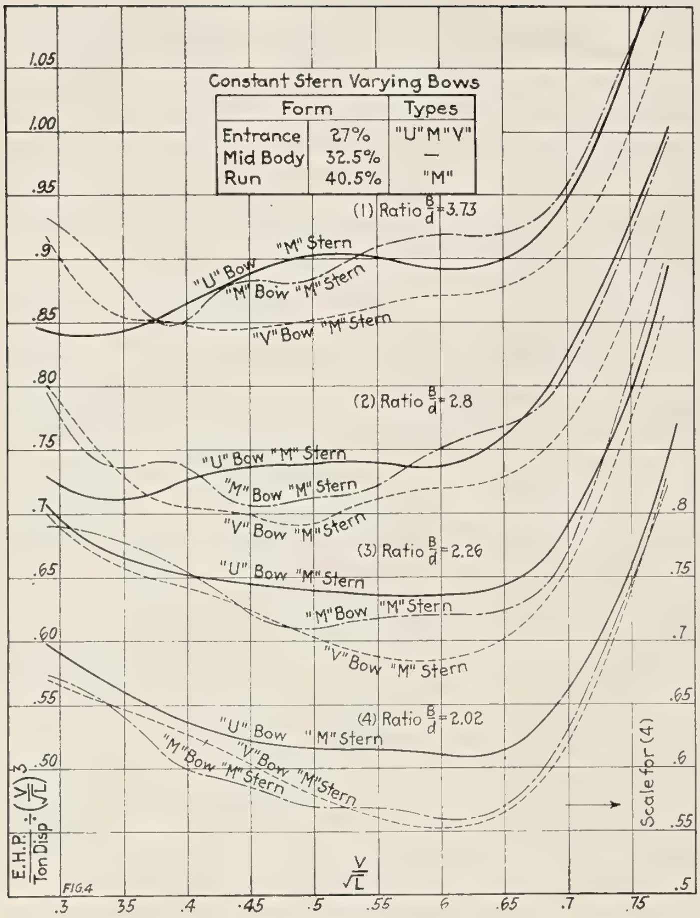

Fig. 4

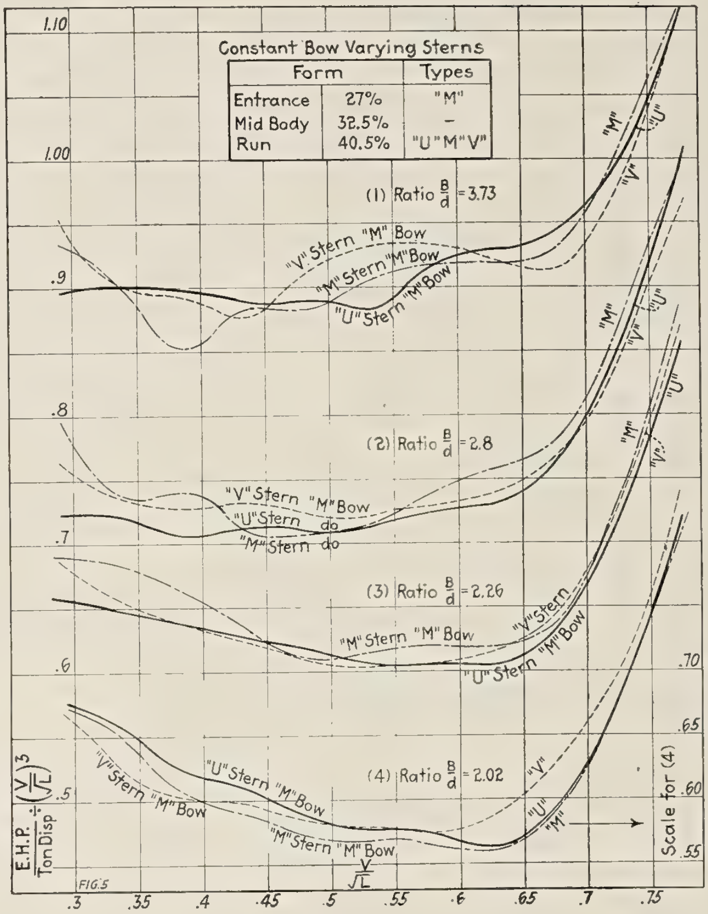

Fig. 5

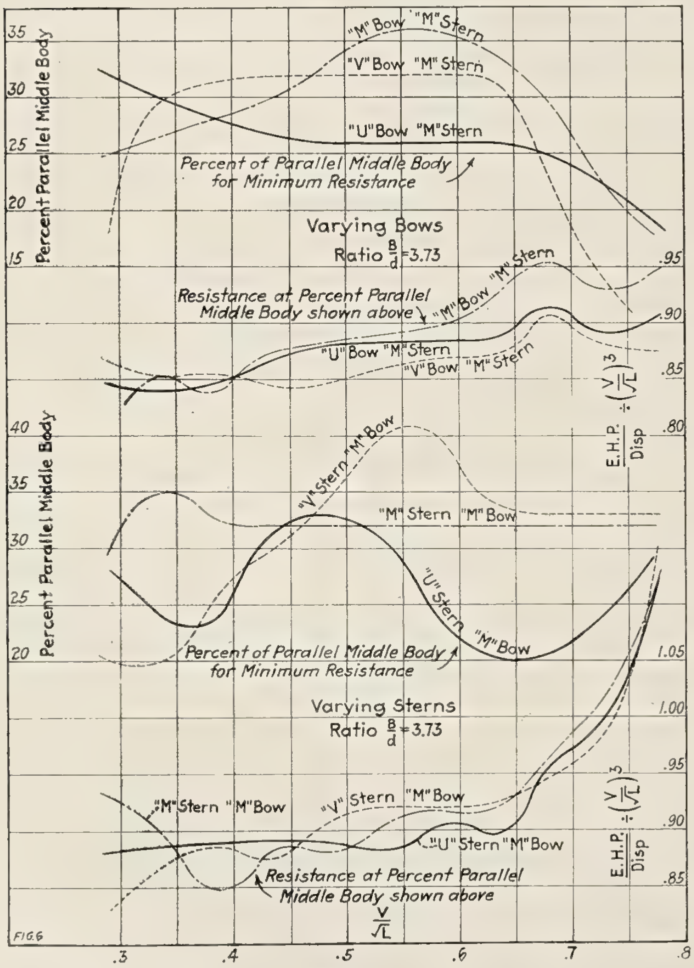

Fig. 6

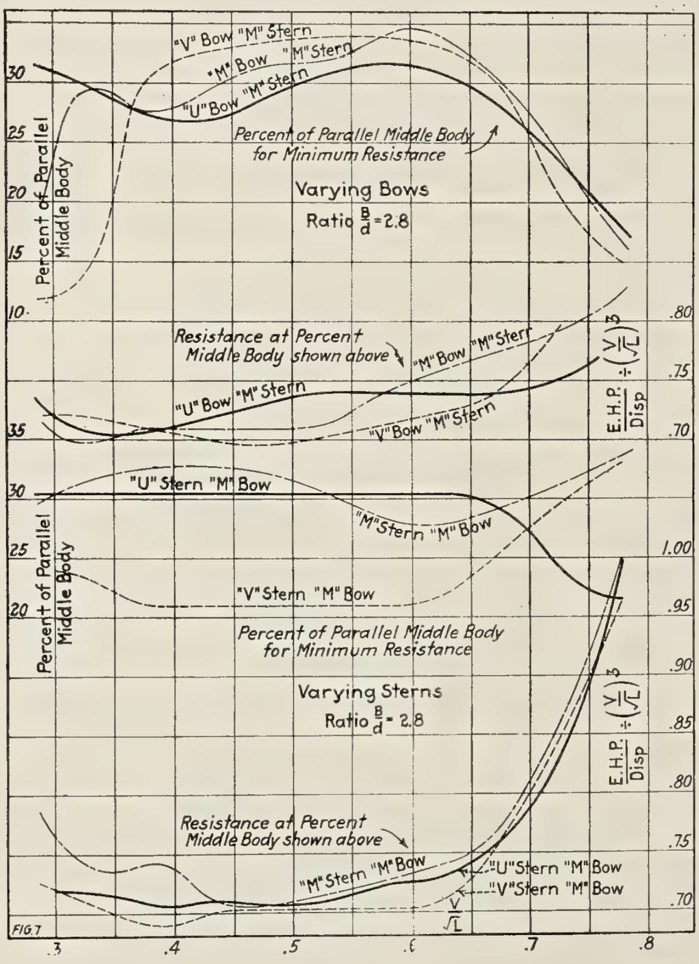

Fig. 7

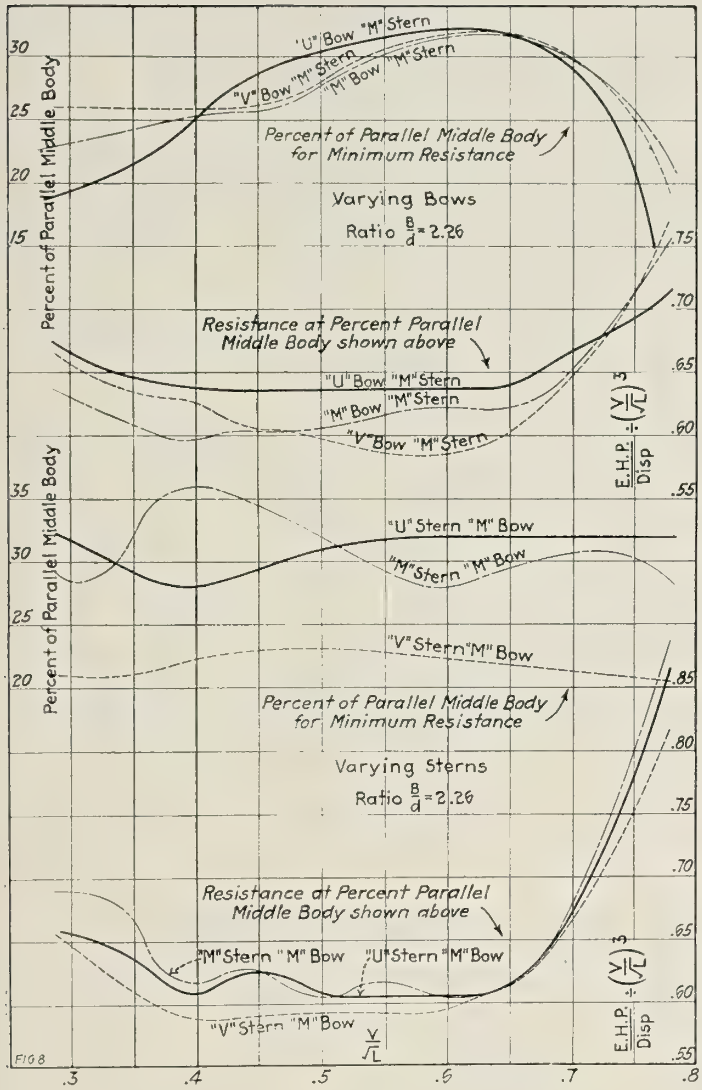

Fig. 8

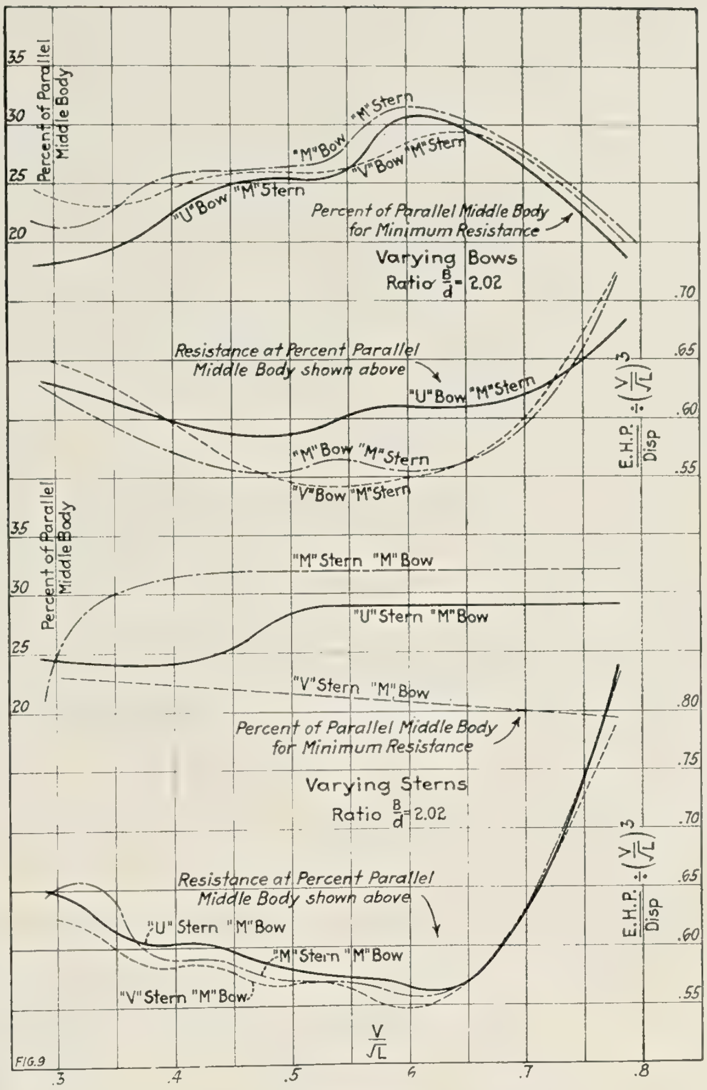

Fig. 9

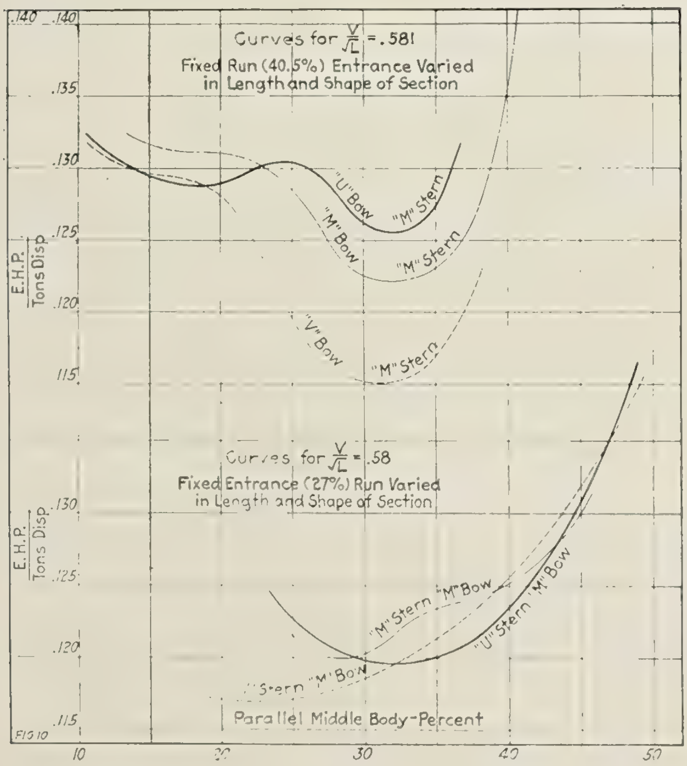

Fig. 10

varying of the shape of section of the vessel and to bring them into the limited dimensions of the volumes of our transactions, some of the figures have been modified by a factor representing the cube of the speed-length ratio.

Results of Experiments

As a general comparison of U- and V-shaped sections Fig. 3 shows the effect upon the resistance for a full and a fine vessel with (*a*) stern sections and (*b*) with bow sections varied. With regard to the influence of bow sections it is apparent that, within the range of speed suitable for the vessel concerned, the V-shaped sections are best for the full form and the U-shaped sections for the fine form.

When the stern sections only are varied, the influence upon resistance is not so marked, but in general the U-shape appears to give the better results. It should be remarked, however, that the so-called U-sections aft are of the moderate type and not so pronounced as the corresponding bow sections.

The diagrams shown in Fig. 4 and Fig. 5 illustrate, for a selected model, the variation of resistance in terms of speed due to modification of bow sections with a constant medium type of stern, and modification of stern sections with constant medium type of bow; and also the influence of change of draft from the light to the deep load.

Figs. 5, 6, 7, 8 and 9 show the percentage of parallel middle body at which the resistance is minimum for any given speed, and the value of the effective horsepower per ton at that speed. They have been obtained from curves sim-

ilar to that shown in Fig. 10, which illustrates the effect of the various changes for a selected speed-length ratio of .581. Each of the above figures refers to a given draft or, for the models concerned, a variation of breadth to draft of from 3.73 to 2.02.

Conclusions

A study of the diagrams will reveal certain facts which are of interest. In the first place, it is evident that no hard and fast rule can be laid down as to the best type of bow and stern sections for all ships at all speeds; and, in the second, that the best type of section for a given ship at the load draft is not necessarily the best for the same ship at lighter drafts. The selection of the best type of section will depend upon:

1. The speed-length ratio.
2. The fullness of the vessel.
3. The distribution of displacement longitudinally.
4. The ratio of breadth to draft.

Certain rather broad conclusions may, however, be drawn In the finer types of vessels of the merchant ship type and at speed-length ratios over .75 and not exceeding, say, 1.0, the U-shaped bow sections accompanied with moderately V-shaped sections aft, *i. e.*, sections not too full on the waterline, will in general give good results.

In the fuller types and at speed-length ratios in the neighborhood of about .6 or under, the V-shaped bow sections, accompanied with moderate stern sections as above, will, in the majority of cases, give a satisfactory form.

If it is anticipated that the vessel is to run at reduced draft for any appreciable percentage of her time, then the U-shaped bow sections lose their advantage, and a compromise section will prove more satisfactory. Oil-carrying vessels and lake ore carriers are an illustration of the case where the vessel runs for 50 percent of its time at a considerably reduced draft.

The underlying cause of the variation of resistance due to shape of section is probably to be found in the general conditions of stream-line flow at the ends, so that the prismatic coefficient of the ends, combined with the speed-length ratio of ends and also what might be called "diagonal fineness," will influence the results. Admiral Taylor's experiments on stream-line flow around vessels show conclusively that a good deal of the general flow is in a downward direction and, consequently, anything that can be done to make the path as easy as possible; *i. e.*, by paying some attention to the lower parts of the sections, particularly where these fair into the midship part, will probably reduce resistance.

Appendix

The effective horsepower of any ship taken as a model will be

$$\text{E.H.P.}_{1} = (f_1 S_1 V_1^{2.83} + R_w V_1) \times .00307$$

f_1 = Coefficient of friction for model ship.
S_1 = Wetted surface of model ship.
V_1 = Speed of model ship in knots.
R_w = Wave resistance of model ship in pounds.

At the same speed-length ratio the effective horsepower of a similar ship whose dimensions have the linear ratio λ to the model will be

$$\text{E.H.P.}_{2} = (f_2 S_1 \lambda^2 (V_1 \lambda^{.5})^{2.83} + R_w \lambda^3 V_1 \lambda^{.5}) \times .00307$$
$$= (f_2 S_1 \lambda^{3.415} V_1^{2.83} + R_w V_1 \lambda^{3.5}) \times .00307$$
$$\therefore \text{E.H.P.}_{2} = (\text{E.H.P.}_{1} \lambda^{3.5} - (f_1 \lambda^{3.5} - f_2 \lambda^{3.415}) S_1 V_1^{2.83} \times .00307$$

In terms of effective horsepower per ton of displacement, since displacement varies as λ^3:

$$\frac{\text{E.H.P.}_{2}}{\text{Dispt.}_{2}} = \frac{\text{E.H.P.}_{1}}{\text{Dispt.}_{1}} \lambda^{.5} - (f_1 \lambda^{.5} - f_2 \lambda^{.415}) \frac{S_1}{\text{Dispt.}_{1}} V_1^{2.83} \times .00307$$

Where the similar ship is only 10 to 12 percent longer or shorter than the model ship, the second term can be neglected without introducing any serious error, and the effective horsepower per ton obtained by multiplying the similar quantity for the model ship by $\lambda^{.5}$. The power so obtained is for the same speed-length ratio as in the model ship.

As an illustration, the following table has been prepared for a model ship of 425 feet:

Similar ship	λ	Beam	Beam = $\frac{L}{10}$ +	$\lambda^{.5}$	f_1	$f_1 \lambda^{.5}$	f_2	$\lambda^{.415}$	$f_2 \lambda^{.415}$	$f_1 \lambda^{.5} - f_2 \lambda^{.415}$
375	.882	49.5	12.0	.94	.....	.00853	.00913	.949	.00867	—.00014
425	1.00	56.0	13.5	1.00	.00908	......	......	....	......	......
475	1.118	62.5	15.0	1.057	......	.00960	.00905	1.047	.00947	+.00013

At the deepest draft the ratio of wetted surface in square feet to displacement in tons does not exceed 2.9 for the model ship, and for the lightest draft rarely exceeds 4.0.

At the high speed-length ratio for this type of .68, the value of $V^{2.83}$ is about 2,000. Using these values for a similar ship where $\lambda = .882$ the value of the corrections becomes:

$$+ .00014 \times (4 \times 2{,}000 \times .00307) = .0034$$

At the lowest draft the effective horsepower per ton of displacement of the model ship is about .30. If the simplified expression is used, the effective horsepower per ton for a similar ship will be $.3 \times .94 = .282$; and if the complete expression be used it will be $.3 \times .94 + .0034 = .2854$ at the same speed-length ratio.

In this extreme case the correction amounts to a trifle more than one percent.

Naval Architects to Hold Spring Meeting

THE Society of Naval Architects and Marine Engineers will hold a spring meeting at the Automobile Club of America, 247 West 54th street, New York, on Friday, May 19, 1922, at 8 P. M.

The meeting this spring will be of special interest to shipowners and operators. This is particularly appropriate at this time because Congress is about to decide whether or not America shall adopt constructive legislation that will insure the successful operation of an American merchant marine. It is of course evident that the future of all members of the society interested in the building of ships, propelling machinery, auxiliaries and of the material and equipment that enter into ship construction depends upon successful ship operation.

Capt. Eugene E. O'Donnell, manager, marine department of C. H. Sprague & Son, will deliver a paper entitled "Operating Problems of the American Shipowner."

Through the courtesy of the International Mercantile Marine Company it has been arranged for the members of the society to visit and inspect the *Majestic* from 2 to 5 in the afternoon. This ship is the largest vessel afloat, having a gross tonnage of 56,000 tons, which is nearly 10,000 tons larger than the *Olympic*. It presents many elements of design and construction of interest to members of the society, so than an inspection of the ship should prove of great interest and value to them.

An informal dinner will be served at the Automobile Club of America at 6:30 P. M. At this dinner there will be no formal speeches, but there will be an address by a distinguished authority on shipping matters.

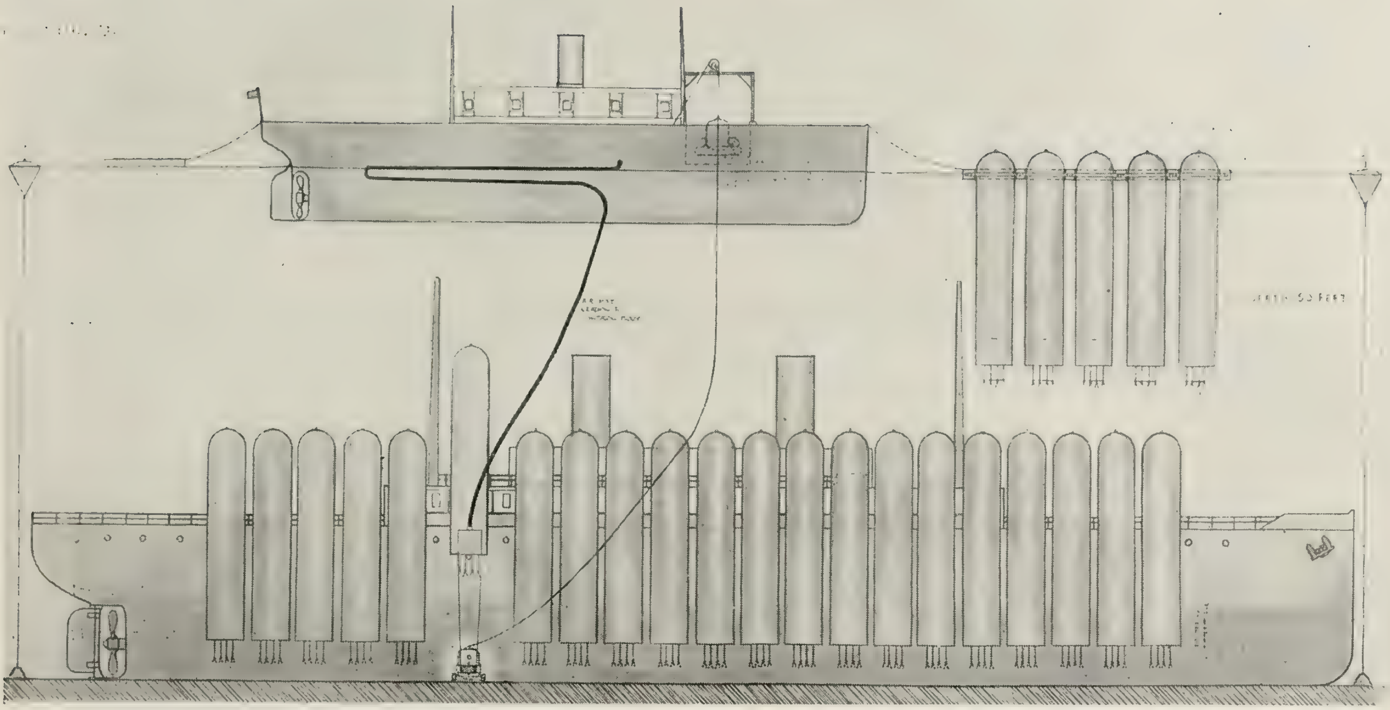

Fig. 1.—Sketch Showing Arrangement of Mother Ship, Submarine Tractor and Vertical Submerged Pontoons for Raising a Sunken Vessel

Vertical Submerged Pontoon System to Salvage Ships

Details of Proposed Method for Restoring Buoyancy to Sunken Vessels at Depths Up to 500 Feet

SYSTEMS of ship salvage employing surface pontoons have been used with success in raising vessels sunk in comparatively shallow waters, but although methods have been devised attempting to utilize similar principles in deeper water none has so far been particularly successful. A method recently developed, however, by Mr. Jesse W. Reno of New York, known as the Reno marine salvage system, offers possibilities for accomplishing the raising of vessels sunk at depths up to 500 feet by attaching a number of vertical submerged pontoons to the sides of the vessel and thus supplying the necessary buoyancy to bring it to the surface.

The location of the ship to be raised is first marked by two buoys at the bow and stern and a mother ship having control of the salvage operations is moored by cross anchors in a convenient position. In order to prepare the vessel for raising, a mobile working chamber, or submarine tractor, having two operators within it is lowered from the mother ship to the sea bottom. This submarine chamber is fitted for propulsion on the sea bottom with caterpillar tractor belts driven by an electric motor within the chamber. This motor also serves to drive twin boring drills and a windlass mounted on the platform of the machine. Current for the motor and for searchlights within the chamber is supplied from the mother ship as is also compressed air for filling the pontoons. Telephonic communication is provided through the lowering cable. Work is carried on in the submarine chamber under atmospheric pressure. The oxygen supply and the method of removing impurities from the air are similar to those employed in submarine boats.

With the working chamber on the sea bottom, the searchlights being turned on, the tractor belts are set in motion and the chamber brought alongside the ship where sets of 5-inch holes are bored through the ship's plates. These holes are located adjacent to the frames of the vessel so that subsequent strains in lifting are transmitted to the entire structure of the ship. The drills work simultaneously and tests have shown that a pair of holes can be completed in 4½ minutes. In the case of small vessels, holes are drilled in sets of four while in larger ships eight holes are necessary to accommodate the large size pontoons.

Arrangement of Lifting Pontoons

The second operation is the attaching of the pontoons which are cylindrical steel tanks closed at the top and open at the bottom. For general service it has been decided that pontoons 12 feet in diameter and 60 feet long are suitable, the number required being determined by the size of the ship to be raised. A vessel with pontoons attached is shown in Fig. 1. Fig. 2 indicates the method employed in attaching the lifting cables. These cables hang down from transverse girders within the pontoons and equalizing levers are arranged to insure equal loading of the cables. At the lower end of the cables are standard crane hooks which are inserted in the holes drilled in the ship's sides.

When preparing to sink the pontoons for attachment to a vessel they are partially filled with air, but only enough to keep them upright. This point is determined by an air valve in the head of each pontoon located so that surplus air escapes until the pontoon sinks in the water leaving its top awash.

The winding drum mounted on the submarine tractor is next brought into action. Two lengths of wire cable spaced about 8 feet apart and long enough to reach the surface are

unwound and a hollow steel float attached to them raises them to the surface. This float is fitted at the top with a hook made to fit into a staple near the bottom of each pontoon; the float being at the surface, a diver places his feet in suitable recesses in its side and signals the working chamber at the sea bottom to pull him and the float down. When he reaches the bottom of the pontoon he inserts the hook of the float in the staple of the pontoon and his work being complete, rises to the surface, after which the pontoon is drawn

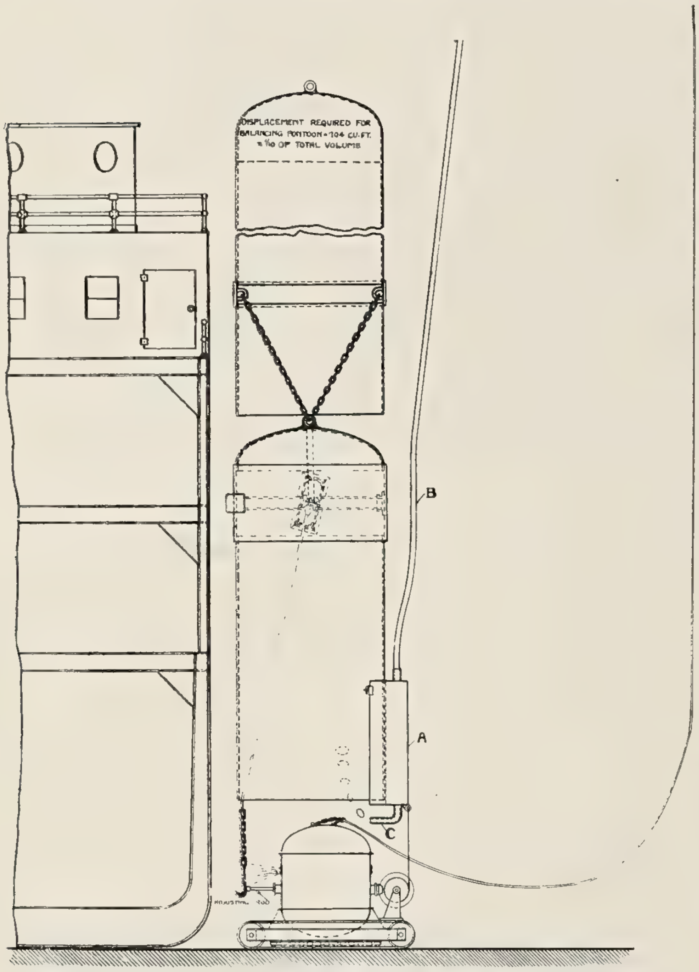

Fig. 2.—Method of Attaching Pontoon to Sunken Vessel by Submarine Tractor

to the bottom. The two cables insure the pontoon going down in proper position and a specially designed adjusting bar operated within the working chamber inserts the pontoon hooks in the holes drilled in the ship's side, Fig. 2.

Raising the Ship

With the pontoons in place it only remains to fill them with compressed air to raise the ship to the surface. A sea bottom syphon delivers the compressed air from the mother ship into each pontoon in turn. The end pontoons are first filled, those on the two sides alternately, to insure the proper balance, when the ship rises until it floats with its decks awash. From this point on the methods followed depend on the tides. If the rise of tide is sufficient, the ship is towed into shallow water, grounded at high tide and the pontoons removed. As the tide falls the water within the ship runs out through the numerous holes which at low tide are plugged by divers. The damage which caused the vessel to sink is patched and as the tide rises again the ship floats with her deck well above the surface of the water ready to be pumped out and towed into dock.

In locations where there is little or no tide a series of partially inflated box shaped pontoons may be placed under the vessel. The side pontoons are then partly deflated and drawn down one at a time by the cable drum on the working chamber and hooked along the lower edge of the box pontoons. The holes in the ship are then plugged, the box and side pontoons fully inflated and the added buoyancy raises the ship with its deck well above the surface ready to be pumped out.

Annual Meeting of the Institution of Naval Architects

THE Institution of Naval Architects held its annual meeting in the lecture hall of the Royal United Service Institution, Whitehall, W. C. 2, London, England, on April 5, 6 and 7, at which the following papers were presented:

"Merchant Shipping and World Commerce in Relation to Sea Power." By Sir Westcott Abell, K. B. E., M. Eng.

"Three Steps in Naval Construction—*King Edward VII—Lord Nelson—Dreadnought*." By J. H. Narbeth, C. B. E., M. V. O.

"Resistance of Ships Among Waves." By J. L. Kent.

"Nodal Arrangements of Geared Drives." By Dr. J. H. Smith.

"Double Reduction Gears in the S. S. *Melmore Head*." By J. W. Wilkie.

"A Method of Determining the Natural Periods of Vibration of Ships." By T. C. Tobin, M. A.

"Possibilities of Fuel Economy in Marine Boilers." By John Reid.

"The Metering of Steam." By J. L. Hodgson.

"Diesel Machinery for Single Screw Motorships." By James Richardson.

"Longitudinal Strength of Cargo Vessels and Its Variation with Fullness of Form." By E. L. Champness, M. B. E., M. Sc.

"Some Special Cases of Two-Dimensional Stress or Strain." By Prof. C. E. Inglis, M. A.

"The Economic Efficiency of Merchant Ships." By John Tutin.

"Recent Developments in Motor Lifeboats." By J. Rennie Barnett, O. B. E.

An evening reception at which the president, His Grace the Duke of Northumberland, received the guests, was held on April 4 and the annual dinner of the Institution was held on Wednesday, April 5.

The Council is arranging to hold a Summer Meeting of the Institution in Paris on July 4, 5 and 6, particulars of which will be issued in May.

New Type Expansion Joint

THE Ray Expansion Joint Company, Inc., of 95 Liberty Street, New York City, has recently introduced in the marine field a new type expansion joint consisting primarily of two flanges connected together by means of a flexible element, the flanges being guided relatively to each

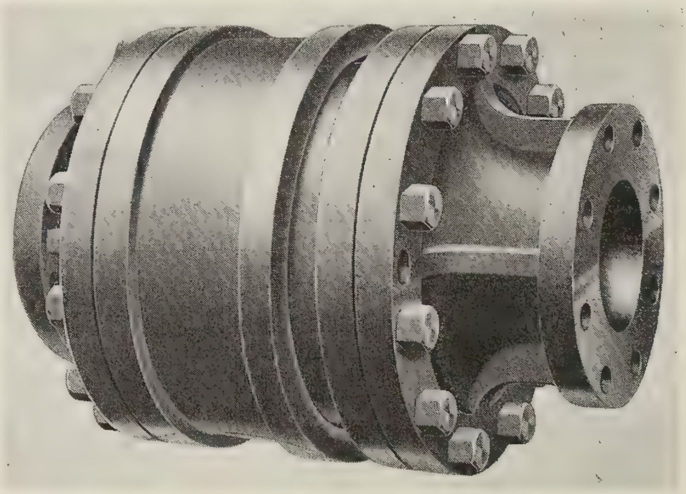

Fig. 1.—Ray Expansion Joint—Exterior View

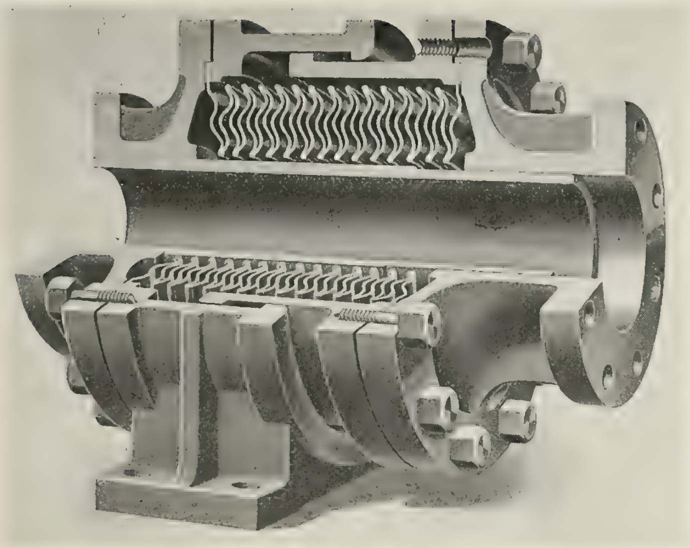

Fig. 2.—Ray Expansion Joint—Section Showing Details of Construction

other in such a manner as to permit longitudinal movement and at the same time prevent lateral movement.

The elastic element consists of a number of corrugated steel discs, alternately welded together at their inner and outer circumferences, the end discs being provided with enlarged flanges for attaching to the flanged end pieces. The discs are pressed from plates of special crucible nickel steel which, when subjected to the particular heat treatment given the completed element, has an elastic limit of approximately 170,000 pounds per square inch and an ultimate strength of about 220,000 pounds combined with great toughness or resiliency. Due to their construction and the special metal of which they are composed, these discs will function for long periods of time without giving way to fatigue caused by the alternating stresses to which they are subjected by the expansion and contraction of the pipe line.

A tube in the bore of the joint acts as a guide for the movable head and in addition to protecting the elastic element from the entrance of foreign bodies between the discs, prevents the escape of any appreciable amount of steam or liquid in case of a breakage in the elastic element. The construction is such that a slight leakage past this tube is kept within the elastic element because the end flanges are made absolutely tight with suitable gaskets.

One of the particular advantages claimed for this joint is the fact that it may be installed in inaccessible places such as the main suction lines aboard tankers and several large oil companies are considering the installation of these joints for this service.

While this new type of joint has not been in service long enough to determine the life of the flexible element under actual working conditions, the manufacturers estimate the life to be from ten to fifteen years. Even should the life, however, be limited to four or five years, the ease with which a new flexible element could be installed and the absence, during that time, of packing troubles would justify its use.

Ray expansion joints are made in standard sizes to resist oil or steam pressures up to 250 pounds and expansions up to three inches. Special designs, however, are available for joints with a total movement up to 16 inches.

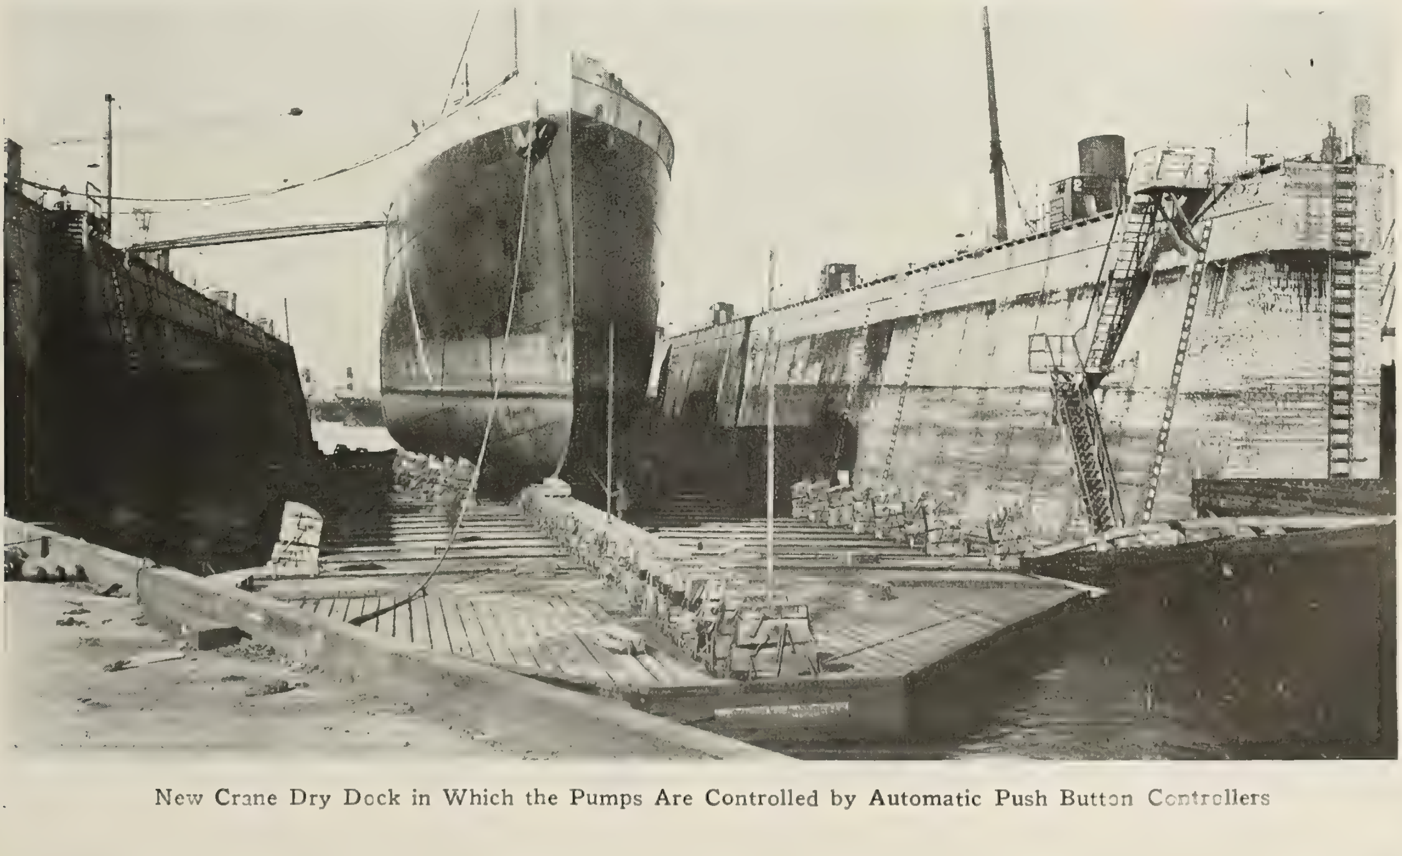
Controlling a Floating Dry Dock With Push Buttons

By James Goldsborough*

ONE of the latest developments in the control of dry docks is illustrated by the 14,000-ton, four-section, floating dock recently erected in the yards of Theodore A. Crane's Sons Company, Erie Basin, Brooklyn, N. Y.

All of the pumps are controlled directly by the dock master himself. He stands in a little house, directly facing the dock, where he has a clear view of all proceedings. Within this house is a waterproof cabinet which contains eight sets of push buttons, each set consisting of two buttons marked "start" and "stop," respectively. The sets are numbered

* Westinghouse Electric & Manufacturing Company.



New Crane Dry Dock in Which the Pumps Are Controlled by Automatic Push Button Controllers

One of Eight 125-Horsepower Motors Operating the Pumps

Dock Master's Push Button Control Station

from one to eight, and each controls one of the eight pump motors in the dock.

To start any or all of the motors, the dock master presses the proper "start" buttons; to stop them, he presses the "stop" buttons. Thus the control of the delicate operation of pumping out a dock is literally at his finger tips, and his days of bawling out orders, with the consequent loss of time and possibility of being misunderstood, are at an end.

This is one of the first instances of automatic electrical control of a dry dock, although this system has been successfully used in other industries, notably in steel mills, for many years.

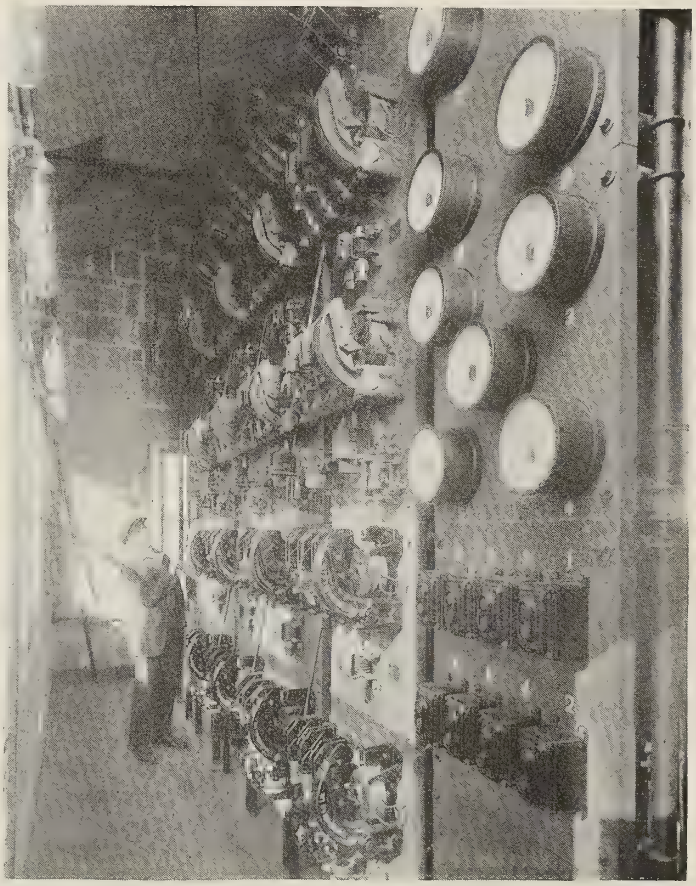
The Controller

The controller itself is located in the yard's substation. This consists of a large panel board carrying eight groups of magnetic contactors, eight ammeters, and eight sets of push buttons, which are duplicates of those in the dock control house. The actual motor connections are made by the contactors (and not by the push buttons), and these are so designed that they close in the proper order and at a rate that will start the motors in the least possible time consistent with safety.

The motors operate on 3-phase, 25-cycle, 440-volt current but are started by being connected with a 220-volt circuit. When the dock master presses the "start" button of No. 1 motor, for example, the contactors are energized and those that connect it to the 220-volt circuit close first. This application of low-voltage current starts the motor easily and brings it gradually up to speed. When the proper speed is attained, a relay mounted on the panel closes automatically, and the 440-volt contactors then close, connecting the motor directly to the running circuit. When the "stop" button is pushed, all contactors open and disconnect the motor.

The ammeters mounted on the control panel give the electrician in charge of the substation complete information as to the performance of the motors. By glancing at these instruments, he is able to determine whether or not each motor in operation is taking its full share of the load. Any irregularities indicated are immediately investigated, and troubles can often be remedied before actually developing

The duplicate set of push buttons in the substation provides control of the motors in case of trouble at the dock house, and also permits the electrician to act in case of an emergency.



Magnetic Contactors in the Yard Sub-Station. At the Right Are the Ammeters, Showing Operating Conditions of Each Motor; Below Them Is the Duplicate Set of Push Buttons

The motors are of the vertical squirrel cage type and are rated at 125 horsepower at 290 revolutions per minute. They are provided with ball thrust bearings and their coils are impregnated to render them weatherproof. They are mounted in little houses on the deck of the dock, and each is directly connected to an Alberger centrifugal pump.

Current for this installation is received from the Brooklyn Edison Company at 6,600 volts and is stepped down to 440/220 volts by three oil-insulated self-cooled transformers.

The dock itself cost over $1,000,000 and all of the wooden construction was handled by the yard. The marine construction engineer in charge was Henry J. Gielow of New York. All of the electrical equipment was supplied by the Westinghouse Electric & Manufacturing Company.

The Most Interesting Job in the Yard

If you are holding down an interesting job in a shipyard, have you become so absorbed in your own work that you have failed to realize the importance of the work in some of the other departments in the yard? Even if you haven't, it is more than likely that many of the men in the other departments have, and that, through ignorance or indifference, they know little about your job or its importance. Here is a chance for you to tell them, as a loftsman is doing in the letter printed below, and as others have done in previous issues, why yours is the most interesting job in the yard. Who's next!

While I am willing to acknowledge, when merely thinking is concerned, that the draftsman has "the most interesting job in the yard," I will not readily hand him the palm when it is a question of both thinking and acting. It then rightly belongs to the mold loftsman. Being a loftsman by trade, I am ready to defend the attributes of this vocation against all who may be skilled artisans in the marine engineering industry. Yes, even against those literati of the industry who use Latin in their discourses!

The loftsman dwells in an atmosphere of romance as well as accomplishment. Twenty-two years ago a group of American bridge builders began the task of building a ship at Camden, N. J. Confronted with the archaic British method of ship construction these gentlemen asked themselves why a ship could not be built as they had been building bridges. Thus, American inventive genius germinated the idea that has wrought a revolution in shipbuilding. Here, too, the fabricated ship was given birth, with the death-knell being sounded in America to the supremacy of old-world methods as well as old-world shipbuilders. The problems of a ship were found to be vastly different from those of a bridge; but fortitude and determination triumphed. Today the solution of all these difficulties is known to the modern loftsman, even though some are termed "impossible" by classics of the foreign shipbuilding technical world.

Revolution in Shipbuilding Began in the Mold Loft

Formerly the speed of ship construction was governed by the output of the punch shed which in turn relied on steel that had been templeted from the ship, a la the old scrive-board method. Today the mold loft can turn out a ship and keep three shifts going in the punch shed with three shifts of plate-hangers, if need be. The speed of ship construction at present depends, in the main, on bolting and riveting.

Here in the Pacific Northwest—even today a pioneer country—is a shipbuilding establishment (Skinner and Eddy Company, Seattle, Wash.) that made and held all records, during the late crisis, for fast ship construction. The factors entering into this achievement were: an efficient business organization; a capable and energetic works manager; a body of loyal workingmen; and a modern mold loft system. Even though the other factors were double as able, without the loftsman's valuable service no records would have been possible; for Britain, with her age-old family of shipbuilders, would easily have outstripped them. To the skilled art of the loftsman as to no other single factor—aside from the demand—goes the credit of shipbuilding in America emerging from 85th place in American industries in 1914 to 15th place in 1920, thus making us the shipbuilding nation of the world.

What the Loftsman Does

A skeleton outline of a loftsman's duties should convince the most skeptical of the merits of my claim. After the inspired genius of the drafting room has completed the ship's form to a ¼-inch scale, it is sent to the loftsman who lays the design down on the mold loft floor to full size. Working to measurements forty-eight times greater than the draftsman, the loftsman is enabled to round off unsightly corners, thus assuring a finished ship that will be fair and pleasing to the eye. With the completion of the lines, work is begun templeting the various constructional parts such as the frames, bulkheads, decks, shell, foundations, hatches, masts, etc. A paper or wooden templet is made to exact size for each piece of steel that enters into the hull of the ship, ranging from the largest shell plate to the smallest liner. While some parts are flat and some curved, a considerable amount is also twisted, testing severely both the skill and imagination of the loftsman. As all this work is laid out on the flat—in one plane—and although many checks as to its accuracy are applied, the actual success can be known only after fabrication and erection. The responsibility involved in the undertaking is a large one; but results, in percentage of error, show that the loftsman still remains, by a narrow margin, a member of human-kind.

Coincident with the templet work the loftsman provides the ship carpenter with molds enabling him to prepare the building slip for keel laying, stage building, etc. Later assistance is given in launching preparations when the steel poppets and tie plates for sliding ways are made.

The Loftsman's Directions Are Followed in Fabricating and Erecting the Ship

The work of the fabricating shop is carried on as directions of the loftsman indicate, with the following operations being performed on his orders: duplicating mold on steel, punching, shearing, planing, countersinking, knuckling, flanging, rolling, coping, slotting, drilling, chipping, calking, tapping, sawing, burning and welding. The frame bender is materially aided in all work under his care and the plate-furnaceman as well. The anglesmith staples, offsets, box-ends, etc., from molds supplied by the loft, and the solid-smith works flats and rounds, if need be. Even the heavy forger is aided when the occasion demands it.

The plate-hangers' job is now one of comparative ease as

the loftsman, by cutting, arranging and planning, has facilitated the easy shipping of steel. While the calkers and test-gang can make any tank, whether air, oil or water, tight with the aid of a red-lead gun, taps, steel shims, wedges and packing, the loftsman's accurate work has caused this practise to be well-nigh a lost art. In days of old the job of plating the shell of a ship was a nightmare; but, due directly to the loftsman, it is now quite a simple task, the hardest job at present being to secure good shell riveters. On all kinds of hull repairs the loftsman has lately left his mark, having made possible some of the quickest, most economical and largest repairs.

The patternmaker finds the loftsman indispensable on such work as stems, sternposts, sea chests, hawse pipes, bollards, chocks, torpedo tubes, spectacle frames, etc. The inside machinist following closely behind is also aided along these lines. The joiner has recourse to the loft on such work as pilot houses, cabins and quarters. It is thus, too, with the sheet metal worker who is assisted on light-gage bulkheads, ventilation, etc. Cooperation is extended to the boiler maker on condenser and boiler foundations, and in some yards the loftsman lays out uptakes, smokestacks, feed and filter, fresh water, gravity and sanitary tanks of all kinds. Out on the ship the loftsman assists the outside machinist in locating the position of pumps, engines and propeller shafting for boring. For the painter the freeboard marking, paint lines and draft marks are located. Incidentally, any work on board the ship entailing a knowledge of geometrical construction is performed by the loftsman.

The Language of the Blueprint

My contemporary, the draftsman, states that all "Nulli Secundus" has left to do is to "read the plan," which would be a simple matter, if it were on a par with reading Greek or Chinese for instance; then, when errors arose, they could be proved by the known laws of grammar. However, the language of the blueprint is not yet an exact science, all of which is known to the draftsman and offers him a nice loophole for escape when controversies arise. Even though it were, I believe that some of the more astute wielders of the right-line pen would claim the disputed points to be idioms, not readily understood by the yard force.

Hull construction foremen and superintendents possess a valued stock in trade called executive ability; but it will be found that this quantity—however elusive and intangible—varies in proportion to the very "practical" accomplishments of the yard's mold loft. The ratio would probably be thus: executive ability varies inversely to the cube as does the inefficiency of the mold loft directly to the square.

The Mold Loft a Clearing House of Information for the Whole Yard

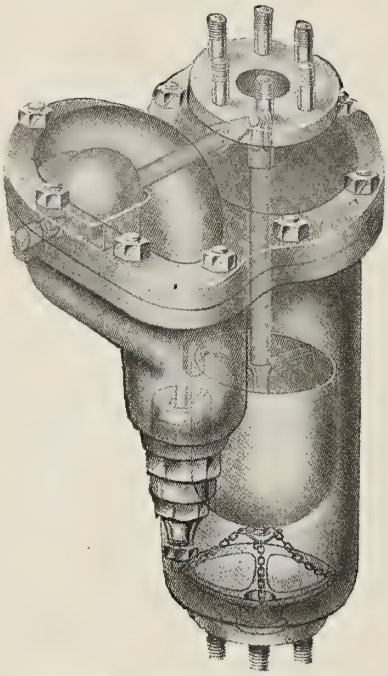
The mold loft is now a clearing house of information for the whole yard and the perfecting of the modern loft is the result of the cumulative effort of the men comprising its personnel, aided and encouraged by executives of vision. Unobtrusive perhaps the loftsman may be, and little seen or heard, yet his is a humility born of greatness. The multiple punch has tended to detract somewhat from his laurels and further inroads may be made with the perfecting of the welded ship; but in this march of progress the loftsman joins; for having in the past been a trail blazer he can still be found adapting himself to changed conditions and ever being a member of the vanguard of progress.

Seattle, Wash. Angus D. MacDonnell.

Shipping Board's Operating Loss in February.—The loss of the operating department of the Shipping Board for the month of February was reduced to $3,089,459, according to an announcement by Chairman Lasker. This was the best showing the board has yet made for any month. When the present board took office last year the average losses were between $11,000,000 and $12,000,000 a month. About 400 ships are now in operation, which is less than were being operated at that time, but freight rates are lower than then and the board is covering all trade routes. For January the operating loss was $3,445,447. The loss for February includes $593,290 on voyage operations. The tankers alone earned a profit of $534,481; charter hire amounted to $65,411; cost of repairs to $1,050,000; lay-up expenses to $413,076; insurance premiums to $320,355; salaries and wages to $477,546, and general expenses to $300,000. The board is not yet making public a detailed statement because it is still experimenting to ascertain the proper reserves to be used and it is stated that the loss might possibly be increased by some $400,000 if the reserve set up for repairs proves inadequate.

Automatic Oil Shut-Off for Oil-Fired Boilers

With the increased use of oil as a fuel aboard ship the necessity of providing an automatic check to the fuel feed in cases of low water in the boilers caused the Todd Shipyards Corporation, New York, to develop a device known as the Todd "Guardian" to eliminate this cause of danger in the boiler room of a steamship.



Safety Fuel Feed Shut-off

The device is operated solely by the changes in water level in a boiler which act on a bucket float partly filled with water suspended in one chamber of the apparatus. This float, as will be seen in the accompanying phantom sketch, is arranged with an anchor and chain suspension, which keeps it from touching the sides of the chamber. In addition to the float chamber, a similar chamber is cast in the body of the device at the top in which a cradle containing a steel ball is placed. The float bucket and cradle are connected by means of a rocker arm and spindle. The steam connection is at the top of the chamber and the water connection at the bottom.

When the water level in the boiler falls, it also drops in the float chamber until the danger level is reached, at which point the weight of water in the bucket produces a strong downward pull on the spindle connecting the cradle. This action of the spindle tips the cradle sufficiently to roll the ball from its place whence it drops on the ram head of a cartridge placed in the bottom of the chamber. The ram has a peculiarly shaped point which perforates a copper disk and allows the steam to escape through the opening thus made. This steam enters a stop valve above the diaphragm which automatically shuts off the oil fuel supply to the burners.

The cartridge is a complete unit in itself and can be inserted after the device has functioned. Before it is put in place, however, the ball must be pushed back into the cradle by means of a rod.

Cement and Concrete for Shipbuilding Purposes

By Horace Holden Thayer *

Continuation of a series of articles containing information regarding shipbuilding materials and their uses that is not readily obtainable from shipbuilding handbooks and other generally available sources. The articles are not intended to be a complete exposition of the subject but will be found to contain items of value to the various classes of workers in this field who have to deal with these materials from the materials' point of view.

WHEN the word "cement" is used without qualifying adjectives in connection with shipbuilding work, it is generally understood to be a mixture of Portland cement, sand and water which might more properly be called Portland cement mortar. Concrete is invariably such a mixture together with coke or other so called coarse aggregate. A few special cements which may properly be considered in this article will be dealt with at the end of the article.

Tentative standard specifications have been prepared and submitted as a progress report by a joint committee on standard specifications for concrete and reinforced concrete made up of representatives of the American Society of Civil Engineers, American Society for Testing Materials, American Railway Engineering Association, American Concrete Institute and the Portland Cement Association. When these specifications are hereinafter referred to they will be called "Tentative Standard Specifications."

The Concrete Ship Section of the United States Shipping Board Emergency Fleet Corporation, working in close collaboration with the United States Bureau of Standards did a vast amount of research and experimental work necessitated by the concrete ship construction program. When reference is made to their work or the results obtained from it they will be called, for short, the "Shipping Board."

Nature of Cement and Concrete

The Portland cement in cement and concrete mixtures is partly dissolved by the water and partly held suspended in the solution. It passes through a succession of chemical reactions and eventually begins to set by the formation of interlocking crystals and by the development of colloids or glue like masses. These crystals and colloids acting by themselves have comparatively little strength but when acting as a binder between the particles of sand in cement or as an active part of this cement in the voids of the coarse aggregate of concrete, they develop great cohesive and adhesive power and form an artificial stone.

Reinforced concrete is not rigid but is quite elastic within a moderate range. It is not brittle and is most difficult to break up. Local shocks may puncture it if heavy enough and heavy shocks may cause cracks, but these do not destroy the efficiency of the concrete as a whole. Concrete itself apart from any free alkali content is not affected by sea water.

The proportions of the different elements in concrete have been pretty well standardized for ordinary practice, but for special work like the construction of concrete vessels, which requires maximum strength and density, accurate tests should be made of any new product as well as of the materials. The latter should be selected, graded and proportioned so that the number and size of the voids will be reduced to a minimum. There should be sufficient Portland cement to thoroughly coat every particle of sand and coarse aggregate and to fill all voids between the particles of sand; there should be sufficient sand to form with the Portland cement and water an amount of mortar slightly in excess of that required to fill all the voids between the pieces of coarse aggregate; and there should be only sufficient water used to hydrate the Portland cement, to take care of all possible absorption of water by the dry aggregate and to render the entire mass sufficiently plastic to compact itself and to readily adjust itself to the forms.

Uses of Cement

Cement is a valuable product on shipboard. Some of its uses have been already referred to. The more important of them may be tabulated as follows:

Deck covering.
Base for other deck coverings.
In the bottom of steel ships, including the lower turn of the bilge, efficiently covering the plates, frames and rivet heads. This is a classification society requirement.
Between floors in peaks and bilges to avoid water pockets below drainage holes.
Temporary repairs on all ships.
Inside of fresh water tanks.
Cement wash in tanks and double bottom compartments which do not carry oil.
Cement powder dusted into liquid tar on tank tops.
On tank tops.
Under and in front of boilers.
Calking material.
To stop local corrosion.

Uses of Concrete

Concrete is of particular value only for the construction of concrete ships; though it is used on other ships where considerable volumes of material have to be filled in, such as between floors in the peaks, where a saving in weight or cost can be effected by using it instead of cement.

Portland Cement

Portland cement is defined by the American Society for Testing Materials as the product obtained by finely pulverizing clinker produced by calcining to incipient fusion an intimate and properly proportioned mixture of argillaceous and calcareous materials, with no additions subsequent to calcination excepting water and calcined or uncalcined gypsum. A free translation of the foregoing is that shale or cement rock with limestone and possibly a little earth are mixed in the proper proportions to produce the desired material and roasted in rotary kilns. A little gypsum, not over 3 percent, may be added to regulate the setting action. The fused material is ground to a fine powder, which powder is Portland cement.

Very complete and detailed specifications for this material and the methods of determining its properties have been adopted by the American Society for Testing Materials as their Standard specification C9-21, and they have also been made a part of the Tentative Standard Specifications, and been made the standard of the Navy Department, the American Engineering Standards Committee, and other bodies. The requirements of these specifications, which illustrate the essential qualifications of the material, are:

Chemical Limits

The following limits shall not be exceeded:

Loss on ignition, percent 4.00

*Member of the firm of Rossell & Thayer, naval architects and marine engineers, Philadelphia, Pa.

Insoluble residue, percent	0.85
Sulphuric anhydride (SO_3), percent	2.00
Magnesia (MgO), percent	5.00

Specific Gravity

The specific gravity of cement shall be not less than 3.10 (3.07 for white Portland cement). Should the test of cement as received fall below this requirement, a second test may be made upon an ignited sample. The specific gravity test will not be made unless specifically ordered.

Fineness

The residue on a standard No. 200 sieve shall not exceed 22 percent by weight.

Soundness

A pat of neat cement shall remain firm and hard and show no signs of distortion, cracking, checking or disintegration in the steam test for soundness.

Time of Setting

The cement shall not develop initial set in less than 45 minutes when the Vicat needle is used or 60 minutes when the Gillmore needle is used. Final set shall be attained within 10 hours.

Tensile Strength

The average tensile strength in pounds per square inch of not less than three standard mortar briquettes composed of 1 part cement and 3 parts standard sand, by weight, shall be equal to or higher than the following:

Age at test, days	Storage of briquettes	Tensile strength, pounds per square inch
7	1 day in moist air, 6 days in water	200
28	1 day in moist air, 27 days in water	300

The average tensile strength of standard mortar at 28 days shall be higher than the strength at 7 days.

The Navy Department specifications are identical with specifications C9-21 of the American Society for Testing Materials, except that the Navy Department has inserted a sentence in the part of the specifications dealing with the determination of fineness which states that no greater amount of residue on a No. 200 sieve than the above mentioned 22 percent will be allowed.

The Shipping Board specified a more finely ground Portland cement, thereby enabling the production of a more plastic concrete and one subject to less change in volume than when Portland cement of the normal fineness is used. Their specifications require 90 percent to pass a standard No. 200 sieve.

This is probably a good place to state that standard sieves are based on a "Table of Fundamental Data on Standard Specifications for Sieves" issued by the Bureau of Standards in 1920; that they have square openings; that for sieve sizes ⅜ inch and larger the size is the size of the opening; and that the number given to the smaller sieves is the standard number of wires per inch, and the approximate openings and wire diameters in inches are as follows:

	Sieve Opening	Diam. of Wire
200	.003	.002
100	.006	.004
50	.012	.008
30	.02	.013
20	.0335	.0165
16	.0412	.0213
8	.092	.033
4	.20	.05

Sand

The sand or fine aggregate used in cement and concrete must be sharp. Seashore sand will not answer as the particles are worn round and smooth by the action of the water. The sand may be either natural siliceous sand or screenings from crushed quartzite or equally hard rock. It should be well graded and free from dust, clay and other deleterious matter. The Navy Department requirements for sand are that the sand used shall be clean and sharp and shall be such as to pass through a No. 20 sand sieve, and be retained on a No. 30 sieve, the sieves to conform to the standard sieve specifications of the Bureau of Standards; and that sand having passed the No. 20 sieve shall be considered standard when not more than 2 grams pass the No. 30 sieve after one minute continuous sifting of a 200-gram sample.

The Tentative Standard Specifications state that it shall range from fine to coarse and be preferably within the following limits:

Passing through No. 4 sieve	not less than 95 percent.
Passing through No. 50 sieve	not more than 30 percent.
Weight removed by decantation	not more than 3 percent.

They also state that the fine aggregate shall preferably be of such a quality that mortar briquettes, cylinders, or prisms, consisting of one part by weight of Portland cement and three parts by weight of fine aggregate, mixed and tested in accordance with the methods described in the "Standard Specifications and Tests for Portland Cement," will show a tensile or compressive strength at ages of 7 and 28 days not less than that of 1:3 standard Ottawa sand mortar of the same plasticity made with the same cement. However, fine aggregate which fails to meet this requirement may be used, provided the proportions of cement, fine aggregate, coarse aggregate and water are such as to produce concrete of the strength specified.

The standard Ottawa sand referred to is natural sand mined at Ottawa, Ill., screened to pass a No. 20 sieve and retained on a No. 30 sieve. It is the sand that is standard for use when testing Portland cement.

The Shipping Board requirement was that the fine aggregate when dry should pass a standard 3/16 inch mesh screen.

Coarse Aggregate

The usual requirements for the coarse aggregate are that it will be crushed stone, gravel or similar inert material, clean, hard, strong and durable, and free from soft, flat or elongated particles, or alkali, organic or other deleterious matter. Stone and gravel are, however, too heavy for shipboard service.

Coke is a good material when the concrete is used for filling in between floors in vessels and similar service. The Navy Department allows the use of coke crushed to small size where such filling has a depth over 3 inches. They require that a thin coat of cement mortar about one inch thick be first put on; then that the space to be protected be filled with fine coke and a cement mortar grout be poured over it filling the voids; and finally that it be finished off with a 1-inch coat of fresh mixed cement mortar sufficiently stiff to be trowelled to a surface. This is a good procedure to adopt generally.

As weight is one of the great handicaps of a concrete ship, it is essential that the coarse aggregate be as light as possible while still giving the concrete the necessary strength and impermeability. The Shipping Board developed an aggregate of bloated clay which floats on water. Concrete made of it weighs less than 110 pounds per cubic foot, which is 20 percent less than that obtained from normal sand and gravel aggregates. In addition to the light weight it has great strength, giving in excess of 4,000 pounds per square inch (in 28 days) in mixtures required in ship construction as compared with 2,000 pounds per square inch for much of the concrete used in ordinary building construction. This aggregate also makes a concrete having an impermeability equal to or greater than with sand and gravel aggregates.

The size of coarse aggregate depends upon the character of the work and no attempt is made in the Tentative Standard Specifications to specify it except to define it as aggregate that is retained on a No. 4 sieve, and of a maximum size generally not larger than 3 inches and to limit the amount that will pass a No. 4 sieve to not over 15 percent and the amount that will pass a No. 8 sieve to not over 5 percent. In the Shipping Board's concrete ships, the coarse aggregate when dry was required to pass a sieve having ⅜ inch square openings, and to be retained on a sieve having 3/16 inch round openings.

Water

The water used in making cement and concrete should be clean, preferably of drinking quality, and free from oil and alkali or other deleterious substances. The Shipping Board required samples to be submitted for their approval.

The amount of water used in making concrete is an important factor. There should be sufficient to take care of the duties previously mentioned and, with these taken care of, the less excess water the better. With too much water the crystallization of the Portland cement may be incomplete and the slower hydration into colloid forms be badly affected. An excess of water tends to prevent the deposit of a uniform film of the hydrating cement on all surfaces of the aggregates and tends to allow the larger and heavier pieces of aggregate to sink to the bottom, where they form a definite stratum poorly connected together and often so full of voids as to provide easy passage to percolating water. With very wet mixtures any fine sand or dirt will flow to the surfaces and into the corners and result in crazing and cracking. An excessive use of water is particularly serious in concrete for shipbuilding purposes because the porosity of concrete results to a considerable extent from the leaching out or evaporation of excess water; the greater the amount of water, the greater the volume of the pores or voids, both strength and permeability being thus affected.

It has been proven that the strength of concrete decreases rapidly when the water content is increased beyond a certain point. This point for any particular mixture is difficult to determine exactly on account of the great variation in absorptive properties of the aggregates, even when from the same source. The Bureau of Standards has compiled a great deal of information regarding this in their Technologic Paper No. 58, on the "Strength and Other Properties of Concrete as Affected by Materials and Methods of Preparation." They show that a gravel concrete requires less water than a crushed sandstone concrete, and a crushed granite concrete requires less than either. They conducted a large number of compression tests in which aggregates from many sources were used in varying proportions, with a measured water content modified as required by the differing coefficients of absorption of the aggregates to produce mixes of certain consistencies, of which the three most commonly used are defined by them as follows:

Quaking—A stiff mixture upon which water can be brought to the surface by slight tamping. The mass should not flow readily.

Mushy—A soft, mushy mixture which is not watery, but can be spaded and readily worked into place in the form.

Fluid—A watery mixture which flows readily into place in the form with little or no working.

Typical figures from these tests, made with small cylinders of one color, two colors and four colors, mixes of crushed granite and of gravel concretes are:

Ultimate Stress in Pounds per square inch
Crushed Granite
Concretes

Consistency	*Fluid*	*Mushy*	*Quaky*
Percent water	9.0	8.0	6.9
Age—4 weeks	2683	3480	4000
Percent water	9.0	8.4	7.0
Age—52 weeks	4908	5299	6278

The tests revealed almost without exception that the quaking and mushy consistencies gave the greater strength, the former, in all but a few cases, giving better results than the latter, while the fluid or watery mix made a comparatively poor showing.

In the report accompanying the records of the tests, it is stated that the most satisfactory consistencies of concrete, from the standpoint of strength and durability, are the quaking and mushy mixtures and the error should be made

Questions and Answers for Marine Engineers

Inquiries of General Interest Regarding Marine Engineering and Shipbuilding Will Be Answered in This Department

Conducted by James L. Bates

This department is maintained for the service of practical marine engineers, draftsmen and shipbuilders. All inquiries should bear the name and address of the writer. Anonymous communications will not be considered. The identity of the writer, however, will not be disclosed unless the editor is given permission to do so.

Design of Hand Gear for Steam or Electro-Hydraulic Steering Machinery

Q. (1154).—When designing a hand gear for a steam or hydraulic-electric steering gear, what is the ratio of power required to that of the main gear? In other words, how many pounds pull and at what speed should it be applied to the hand wheels? How long should it take the hand gear to pull the rudder from hard over to hard over in the event of the main gear having broken down? Are there any books or pamphlets published dealing with the design of deck machinery?

A. (1154).—The following tabulated data will, it is thought, answer your questions better than a more general discussion:

	No. 1	No. 2
Type of ship	Passenger	Tug
Displacement in tons	10,000 to 12,000	200 to 225
Length in feet	460	85
Speed in knots, when hand steered	about 10½	9 to 10
Number of men at hand wheels (total)	6	1
Number of hand wheels	3	1
Type of main steering gear	electric screw	hand
Diameter of hand wheel to center of grips, inches	72	48
Diameter of rope drum, if fitted, inches	..	6
Hand gear connection to main driving shaft	clutched direct	..
Screw gear, double acting	7¼" outside dia., 1½" lead	..
Radius of rudder crosshead or tiller, inches	28	54
Pounds pressure at steering wheel per man	allowed 30	**28 by test
Type of rudder	single plate, unbalanced	wood unbalanced
Rudder area in square feet	157	33½
Width of rudder in fore and aft direction, inches	111	51
Number of turns of hand wheel, hard over to hard over	..	4¾
Time, hard over to hard over	*90 seconds	..

For comparative purposes the following may be of value:

Kent's handbook gives for a man turning a crank or winch as follows

R = resistance in lbs.	12.5	18	20
V = ft. per sec.	5	2.5	14.4
T = hours per day	..	8	2 minutes
RV = ft. lbs. per sec.	62.5	45	288
RVT = ft. lbs. per day	..	1,296,000	..

Smeaton is authority for the following: "A man draws horizontally 70 to 80 pounds, and thrusts at the height of his chest 28 or 30 pounds. . . . The force of a man in turning a winch is taken at 116 pounds."

I am unable to refer you to a book on deck machinery. I should say that conscientious study of the principles of machine design as applied to the design of the different types of deck machinery for which you might be able to secure detailed information from the manufacturer is about the only course open to you.

*This is an extreme arc of 35 degrees from about 20 degrees one side of center line to 15 degrees the other, it being impracticable to obtain more with the hand gear.

**This was found too great for satisfactory continuous operation. It was reduced to about 18 pounds by the introduction of a 2 part purchase in each tiller lead

Metacentric Height and Freeboard for a Tug

Q. (1155).—Do you consider 18 inches of metacentric height sufficient for a tug? Is 2 feet of freeboard enough?

A. (1155).—It is assumed from the figures given that you have in mind a harbor tug, steam driven, and from 85 to 100 feet in length. Of ten such tugs, for which the writer has reliable data, the metacentric heights are generally in excess of 15 inches, ship light, and from 18 to 30 inches, ship in loaded condition. The freeboards of these tugs at the half length are, in the loaded condition, generally in excess of one foot, while in the normal service condition they approach two feet.

The real criterion is not either metacentric height or freeboard taken individually. It is rather a composite of the value of the maximum righting, the angle of heel at which it occurs and the maximum range of stability. For tugs of the type in question a maximum righting arm of 0.6 to 0.8 foot, occurring at from 25 to 35 degrees angle of heel and a maximum range of stability of at least 50 degrees, all in the normal or service condition, should give satisfactory results.

Weights of Auxiliary Machinery

Q. (1163).—Will you please give separate formulas for determining the weight wet and dry of each of the following auxiliary engines: Condenser, heater, air pump, feed pump, etc. Also for the weight of the following machines: Lathe, planing machine, slotting machine, motor, drilling machine, etc.?

A. (1163).—The writer is unable to answer this question as fully as he would like, owing to the fact that machinery weight estimates are usually determined where possible by comparison with data already at hand of similar units; or, where information is not available for comparison, they are usually obtained from the manufacturers.

It would be impossible to derive formulas which would cover condensers as a class, owing to the fact that the type of vessel upon which they are to be installed generally governs their design as to form and lightness. What has been said of condensers also applies to other units.

The following are a few approximate rules which may be used for weight estimates:

Condensers, shell, of plate construction.	Dry	Wet
Heavy naval and merchant marine, pounds per square foot	5 to 6	6 to 7
Auxiliary condensers	5½ to 6½	6¼ to 7¼
Light fast craft	3½ to 4	4¼ to 4¾

Feed water heaters, shell, of plate construction.

Coil type, pounds per square foot, dry	= 12
Film type, pounds per square foot, dry	= 24
Straight tube type, pounds per square foot	= 5 to 6½

Air Pumps: For dry weight allow about 480 pounds per cubic foot of volume swept through by all pistons; i. e., 480 times the total area corresponding to the diameters of all pistons multiplied by the length of stroke.

LETTERS TO THE EDITOR

Diesel Electric Propulsion Versus Direct Drive

The article appearing in your February issue by Commander S. M. Robinson entitled "Diesel Electric Propulsion of Ships" has been read with much interest, as this subject is at present keenly discussed in this country, and pronouncements from brother engineers in the States are given close attention.

While in the main, the views of the author appear to be substantially the same as those of the leading engineers here, there are some statements made with which agreement cannot be expressed, and this letter is written with the object of obtaining further elucidation as to what is in the author's mind.

The statement that the Diesel is inherently poor in maneuvering qualities is far too sweeping an assertion to make and, while this reproach may be leveled at some designs, yet in the type built by my firm, Messrs. William Beardmore & Company, Dalmuir, Scotland, i.e., the Beardmore-Tosi four-stroke engine, these qualities of maneuverability and flexibility excel those of a steam engine. In the motorship *Pinzon,* recently completed—a single screw ship of 1,200 brake horsepower—the response to an intensive series of 85 telegraph orders was perfect. In this engine the speed can be reduced without misfiring to one-fifth of the designed full speed. While it is quite true that air must be used for this purpose, yet, it is not clear why air at 350 pounds per square inch pressure should be "not only entirely unsatisfactory, but distinctly bad," while injection air at 1,000 pounds is—except in the case of the few solid injection engines—essential for the operation of the engine at all, whether driving a generator or a propeller. While it is admitted that air starting bottles may be dispensed with, injection air bottles still remain.

It is agreed that the higher the speed of revolution, the more efficient the engine as a prime mover for driving generators becomes, but it is undoubtedly a fact that the fast running engines driving dynamos in present motorships give infinitely more trouble in their maintenance than the relatively slow moving main propelling units, and there is a general tendency in this country to limit the speed of such machines to 250 revolutions per minute. (With a multiplicity of these small fast running units installed in a high powered ship, the lot of the engineer would scarcely be enviable.)

Commander Robinson quotes an example of a 2,000 shaft horsepower ship driven by twin Diesels at 150 revolutions per minute, but such a practice is practically unheard of over here, the figure being usually 110 to 120, which with a twin screw vessel does not mean excessive loss of propeller efficiency, whereas a 2,000 horsepower motor running at 90 revolutions per minute is an enormous and costly item and provides no stand-by in case of disablement.

In discussing the choice of current, Commander Robinson's remarks regarding the use of series coupled direct current machines are quite concurred in but, so far, it does not appear that a case for alternating current for any ship of the powers at present suitable for Diesel electric drive can be made out. The necessity for extremely close governing and the maintenance of the propelling motors at a speed corresponding to the periodicity, irrespective of the fact that the alternator is essentially a machine more suitable for running at thousands of revolutions rather than hundreds, would put this type quite out of the running as a commercial proposition.

The statement that the Diesel electric drive would be suitable for installation in the Emergency Fleet Corporation ships with a resulting fuel consumption of one-third of the present figure seems to be open to question. It is highly improbable that this drive could be accomplished under 0.5 to 0.6 pound per shaft horsepower hour, so that if the existing turbine plant utilizes three times this amount, i.e., 1.5 to 1.8 pounds of oil, then there is something radically wrong with the present equipment.

For double purpose, vessels of moderate power, such as trawlers, cable steamers, ferryboats and, in some cases, yachts, the Diesel electric drive is ideal, the sole detriment being its first cost, but for very high powers, e.g., the 48,000 horsepower design shown for a capital ship, it is quite outside the range of practical possibilities at the moment. A six cylinder engine developing 1,000 brake horsepower per cylinder is still in the future. It is doubtful if any navy would risk installing such an equipment without cautiously feeling its way through the more moderate powers at present successfully tried out, i.e., say 300 horsepower per cylinder.

Commander Robinson closes with the truly amazing statement that the crosshead engine is still in its infancy! He does not appear to realize the limitations of this method of propulsion—excellent though it is in many cases—and would seem to be imbued with the conviction that the system is the one solution for all classes of ships' machinery.

R. J. Butler, M. I. N. A.
Messrs. William Beardmore and Company
Dalmuir, Scotland

Commander Robinson Replies

I have noted the criticism of Mr. Butler, of Messrs. William Beardmore & Company, on my article appearing in the February issue of your publication. Some of these criticisms relate to points on which views must necessarily be merely matters of opinion but others cover points which it would seem that data now available are sufficient to cover and consequently I would like to reply to the criticism on these points.

The first point raised is in connection with the maneuvering qualities of Diesel engines. I think Mr. Butler missed the point of my article in this connection. It is, of course, a well-known fact that Diesel engines can be built which can be maneuvered by the use of air, but it seems to be also a well established fact that such engines have to be built extremely heavy to take care of the stresses set up by this method of control and, if the Diesel engine is to progress and be built in large sizes for marine purposes, it would seem that some other solution rather than air for maneuvering must be found. Mr. Butler makes the point that it is necessary to use air at 1,000 pounds for injection at all times and, therefore, the use of air at 350 pounds for maneuvering should cause no ill effects. I must confess I cannot see the connection between the use of air for injection and the use of air in the cylinders for maneuvering.

In regard to the use of single screws and twin screws, Mr. Butler makes the point that single screws provide no standby in case of disablement. The answer to this is that up to the advent of the Diesel engine practically all cargo ships were built with a single screw, and this seemed to provide sufficient reliability. If electric propulsion is used for a single screw, it would always be desirable to provide two motors for the shaft so that duplication would be provided so far as the machinery is concerned. As regards the comparative efficiencies of single screws and twin screws, assuming the latter can be operated at the most efficient speed, the arguments all seem to be against the twin screws in spite of the data that have been appearing on this subject recently. It is significant that until ships began to be propelled by Diesel engines no one questioned the superiority of the single screw for propulsion purposes.

Exception has been taken to the statement in my paper that a crosshead engine can almost be said to be still in its

infancy. The intent of this statement was apparently entirely misunderstood. It was not intended to convey the impression that reliable crosshead engines were not being built at the present time—in other words, the infant is quite strong and sturdy—but it was intended to mean that the probable development of large Diesel engines will be by the use of this type of engine.

Bureau of Engineering, Navy Department, Washington, D. C.

S. M. Robinson, Commander, U.S.N.

Cement and Concrete for Shipbuilding Purposes

(*Continued from page 333*)

on the side of using too little rather than too much water, providing the concrete is properly spaded or worked into place in the forms.

Some of the valuable conclusions derived by the Bureau of Standards from these tests are:

"A concrete having a desired compressive strength is not necessarily guaranteed by a specification requiring only the use of certain types of materials in stated proportions. Only a fractional part of the desired strength may be obtained unless other factors are controlled.

"The compressive strength of a concrete is just as much dependent upon other factors, such as careful workmanship and the use of the proper quantity of water in mixing the concrete, as it is upon the use of the proper quantity of cement.

"The compressive strength of concrete may be reduced by the use of an excess of water in mixing to a fractional part of that which it should attain with the same materials. Too much emphasis cannot be placed upon the injurious effect of the use of excessive quantities of water in mixing concrete."

(*To be continued*)

PERSONAL MENTION

A. P. Hammond has been selected as Pacific coast manager of the Atlantic Gulf & Pacific Steamship Company.

Frank J. Skala has been made general western agent for the United States Lines. Mr. Skala will have his headquarters in Chicago.

Col. E. H. Shepperd recently retired as comptroller of the United States Shipping Board and has been assigned to do special work with the finance department.

L. M. Stevens, of Philadelphia, formerly general auditor of the United States Shipping Board, has been appointed to succeed Col. E. H. Shepperd as comptroller of the board.

Captain Francis H. Robinson, for the past three years president of the National Interocean Corporation, has been made general freight agent of the Williams Line in New York.

B. L. McMullen has been named Seattle manager for the Crowell & Thurlow Steamship Company. He was formerly in charge of the Sudden & Christensen agency at Portland, Oregon.

Charles F. Duisenberg has been appointed San Francisco agent for the North German Lloyd Steamship Company. This company has not been represented in San Francisco since 1916.

Frank S. Dickson, for some years adjutant-general of Illinois, has been selected by President Harding to become assistant treasurer of the United States Shipping Board and Emergency Fleet Corporation.

Henry Cave, formerly with the London branch of the Shipping Board, has been appointed superintending engineer of the Stockholm district with offices at Stockholm, Sweden.

W. E. Griffith, district director of the Hampton Roads district, has been appointed to the position of manager of the operating department of the United States Shipping Board Emergency Fleet Corporation with headquarters at Washington.

C. J. Janssen has been made freight traffic manager of the United States Navigation Company of New York. He was formerly export freight contractor with R. D. White & Company and prior to the war was with the Hamburg American Line.

OBITUARY

James Tregarthen, president and founder of the shipbuilding firm of James Tregarthen & Sons, died at his home in Brooklyn, N. Y., April 11, at the age of 80 years. He was born at St. Mary's, in the Scilly Islands, England, and served his apprenticeship as a shipbuilder in Newport, Wales. In 1861 he came to America and followed the shipbuilding industry here until his death.

Charles L. Seabury, senior member of the firm of Seabury & de Zafra, Inc., New York, consulting naval architects and marine engineers, died at the New York Hospital, April 7, at the age of 62. He was born at Tiverton, R. I., in 1860, and at an early age began work in the Herreshoff yacht works at Bristol. Later in New York he was with the Gas Engine & Power Company, builders of small boats. Here he was instrumental in developing the naphtha engine, forerunner of the gasoline motor. When he was 22 years of age Mr. Seabury established his own yacht building company at Nyack, N. Y., to carry on the construction of high speed steam yachts, which later made him world famous. During this period of his career, he produced the Seabury safety watertube boiler which was and still is used where high steam pressures and quick steaming are required. Following this, his business became consolidated with the Gas Engine and Power Company at Morris Heights, N. Y., and for many years he acted as vice-president and general manager of this firm. In addition to yacht work, several torpedo boat destroyers were built at the yard. Under his direction, more than 2,000 yachts have been designed and built, including the *Vitesse, Little Sovereign* and *Sovereign,* the latter having a record speed of 40 miles an hour over the measured mile course. During the war, Mr. Seabury was consulting marine engineer with the Foundation Company at Savannah and New Orleans. For the past three years he has been associated with Carlos de Zafra as a consulting naval architect. Mr. Seabury was a member of the Society of Naval Architects and Marine Engineers and the New York Yacht Club.

Charles L. Seabury

Shipbuilding, Reconditioning and Operation

Port Expansion, Passenger and Freight Activities and Other Notes of Interest in All Branches of the Marine Industry

The First Quarter

DURING the first three months of 1922 there was reported in the columns of the Weekly Bulletin a total of $34,927,000 in contemplated ship work and $14,930,206 in actual contracts placed, according to figures compiled by MARINE ENGINEERING AND SHIPPING AGE.

Since January 1 of this year the trend of marine activities has been steadily upward both in new vessel construction and the reconditioning of others. Whether or not it is due to the proximity of the expected passage of the Ship Subsidy Bill now awaiting the action of Congress, there is evidence that the second quarter of 1922 will show even more real business activity for ship builders, repair yards, and equipment companies than the first quarter.

Millions of Dollars to Be Spent for the Construction of 22 Ships Which Are Now Well on Way to Contract Stage

Plans of American Shipowners for Business Expansion Indicate Renewed Activity for Shipyards—Programs Contemplated Include Inland and Coastwise Vessels

ACTUAL building operations on the construction of a total of 22 vessels, which will involve the expenditure of many millions of dollars, preliminary announcements concerning which have been previously and exclusively made by MARINE ENGINEERING AND SHIPPING AGE, are expected to begin in the near future, according to latest indications.

FIVE DIESEL BARGES

It is learned that bids have been received and final decision is now under consideration for the placing of a contract for the building of five Diesel-electric propelled barges for the Canal & Rivers Company, 52 Vanderbilt avenue, and designed by R. R. Livingston, marine engineer, of 2 Rector street, New York City.

The boats, which it is expected will cost about $175,000 each, will be 160 feet long with a beam of 36 feet, depth 11 feet 6 inches, and a capacity of 550 tons. Each vessel will be equipped with two Diesel engines driving generators and two motors driving twin propellers. There will be about 280 horsepower in each boat.

THIRTEEN FREIGHTERS

Awarding of a contract for the construction of 13 special type ocean and lake freighters for the Central Steamship & Commerce Corporation, 30 Broad street, announced by MARINE ENGINEERING AND SHIPPING AGE, February 25, 1922, is looked for in the near future. These vessels were designed by Theodore D. Wells, naval architect and marine engineer of 11 Broadway, New York City. They are to be driven by Diesel-electric engines and will be for service through the Welland Canal and New York Barge Canal between New York and Chicago and also to the West Indies when canal traffic is closed.

FOUR PASSENGER SHIPS

Although it is believed it will be several weeks before definite information is available, it is learned that work is being pushed on the preparation of plans and specifications for the two new passenger ships to be built for the Eastern Steamship Company, of Boston, Mass., which are being designed by Theodore E. Ferris, naval architect and marine engineer of 30 Church street, New York City. These boats will cost approximately one million dollars each and are to be about 400 feet in length, driven by double reduction geared turbines turning single screws, with boilers fired by oil burners. They will carry over 700 passengers.

While no official information was given out concerning the new vessels proposed by the Old Dominion Steamship Company, Pier 25, North River, New York, of which Mr. H. B. Walker is president, it is understood that tentative plans will provide an innovation in coastwise passenger and freight service with the establishment of an express route between New York and Norfolk, Va., with at least two ships, each about 400 feet long and capable of making the passage from New York to Norfolk over night.

Philadelphia Marine Exposition

Indications point to the Annual Marine Exposition to be held in the First Regiment Armory, Philadelphia, Pa., from May 8 to 13 inclusive, as one of the most important events of the kind ever held here. More than 100 exhibitors are expected to take part in the affair.

Preliminary Plans Under Way to Recondition the Agamemnon and Mount Vernon

Announcement is made from Washington that the Shipping Board has voted to have W. F. Gibbs, naval architect and marine engineer, of New York, prepare plans and specifications for the reconditioning of the ex-German passenger ships *Agamemnon* and *Mount Vernon*. It is stated that the Board is seriously considering the putting of these ships in service but whether or not the work will be done will depend largely on the estimates of the probable cost.

Proposed Seagoing Dredges Are Receiving Consideration at Washington

Latest developments with regard to the proposed building of six seagoing dredges, at an estimated cost of about $4,500,000, announced in the Weekly Bulletin of February 11, 1922, indicate that the project is receiving the serious attention of the United States Engineer Office at Washington, D. C., and that, according to present plans, four of the six proposed boats will be equipped with Diesel electric machinery. The remaining two will be steam driven.

It is also learned that the Department is working on the preparation of designs for a steam driven dredge of somewhat smaller dimensions than the 247-footers already proposed.

Contract Placed for Construction of River Type Steel Car Ferry

The contract for the construction of a steel side wheel car ferry for use on the Mississippi River has been awarded to the Charles E. Ward Engineering Company of Charleston, West Virginia. The boat is for the Missouri & Illinois Railroad, and was designed by the firm of Cox & Stevens, naval architects, of 25 Broadway, New York City.

The vessel will be 285 feet in length over all, with a beam over guards of 86 feet, and depth of hull 11 feet, draft 5 feet. She will be driven by two simple engines having a diameter of 22 inches and an 8-foot stroke. Steam will be supplied by six river type boilers.

The steamer will be of the three-track ferry type with machinery and boilers on deck. Delivery is scheduled for the latter part of September, 1922.

May Convert Fireboats to Diesel or Gasoline Power

The City of Portland, Ore., C. A. Bigelow, Commissioner of Public Affairs, is investigating the feasibility of converting its oil burning steam fireboats into either Diesel or gasoline equipment.

Federal Shipbuilding Company Awarded Contract for Building of Merchants & Miners Ships

Vessels Are to Be of Combined Passenger and Freight Type for Service on Atlantic Seaboard—Will Be 368 Feet in Length and Equipped with Modern Improvements

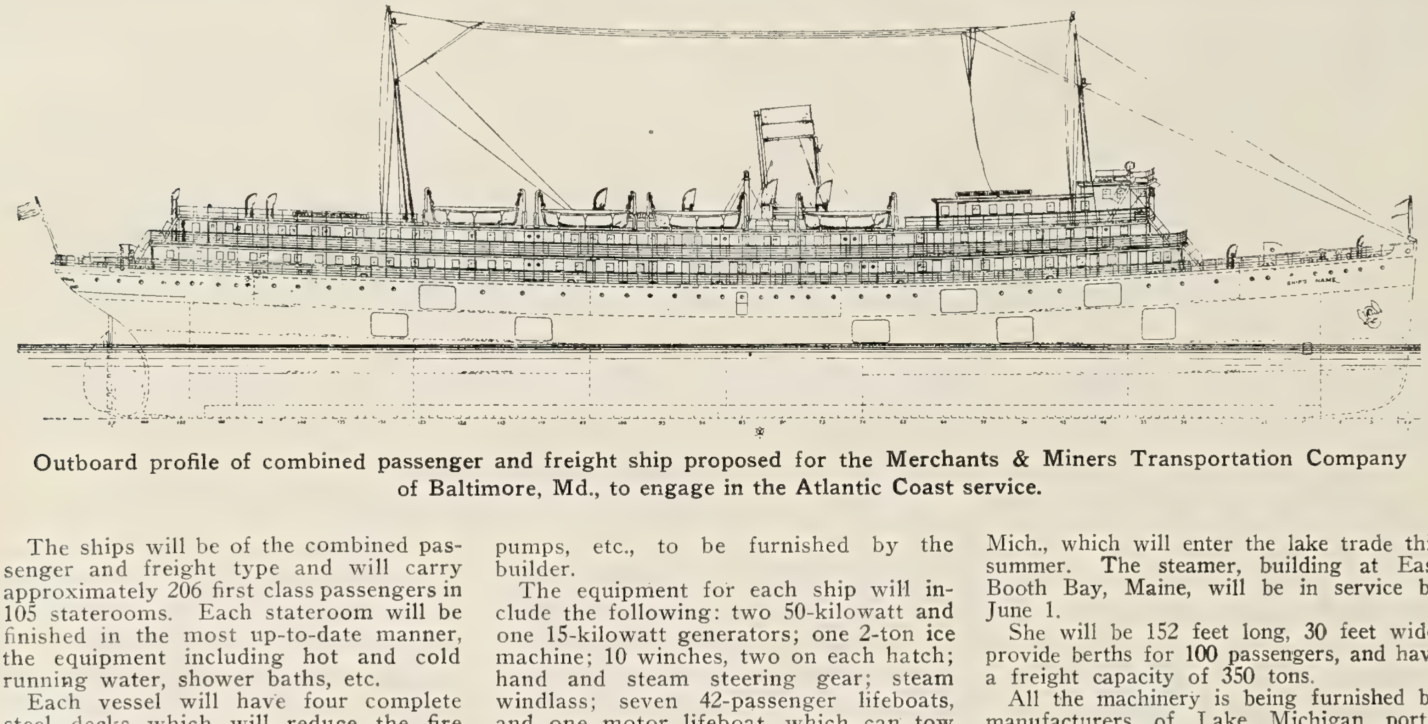
THE Federal Shipbuilding Company of Kearney, New Jersey, has been awarded a contract for the construction of two combination passenger and freight ships for the Merchants and Miners Transportation Company of Baltimore, Maryland. The vessels will be built on the Isherwood system of longitudinal framing.

The type of ship proposed will have an overall length of 368 feet; length between perpendiculars 350 feet; breadth molded 52 feet; depth to hurricane deck 35 feet; depth to main deck 27 feet 3 inches; draft 19 feet; indicated horsepower 2,700; sustained sea speed 12 knots; displacement 7,000 tons.

bulkheads, in accordance with the United States Steamboat Inspection Laws, and the vessels will meet the highest classification of the American Bureau of Shipping. Special attention has been paid to stability and when completed the vessels will be among the safest American passenger ships afloat.

Each ship will be equipped with four, single-ended Scotch boilers equipped with Howden forced draft; oil burners; superheaters and Diamond soot blowers.

The propelling machinery will consist of four cylinder, triple expansion engines developing 2,700 horsepower, the auxiliary machinery including condensers,



Outboard profile of combined passenger and freight ship proposed for the Merchants & Miners Transportation Company of Baltimore, Md., to engage in the Atlantic Coast service.

The ships will be of the combined passenger and freight type and will carry approximately 206 first class passengers in 105 staterooms. Each stateroom will be finished in the most up-to-date manner, the equipment including hot and cold running water, shower baths, etc.

Each vessel will have four complete steel decks which will reduce the fire hazard to a minimum. A system of mechanical ventilation will be installed assuring an adequate supply of fresh air in the staterooms. There will also be

pumps, etc., to be furnished by the builder.

The equipment for each ship will include the following: two 50-kilowatt and one 15-kilowatt generators; one 2-ton ice machine; 10 winches, two on each hatch; hand and steam steering gear; steam windlass; seven 42-passenger lifeboats, and one motor lifeboat, which can tow the others.

The vessels, when completed, are to run between Baltimore or Philadelphia and Savannah or Jacksonville.

Million Dollars Worth of Business Placed with Order for Construction of Three Steel River Type Steamers

THE Louisville & Cincinnati Packet Company has contracted with the Midland Barge Company, of Pittsburgh, for three large side-wheel steel steamers, which it is expected will cost close to $300,000 each.

One steamer, which will be named the *America,* will be used for excursion purposes. This vessel will be 285 feet long with 45 feet beam. She will be equipped with the Mississippi River type of boilers and high pressure, non-condensing engines.

The other two vessels, which will be combined passenger and freight boats, will have a length of 300 feet and a beam of 45 feet. They will be placed on a regular run between Cincinnati and Louisville and will have stateroom accommodations for 175 passengers. It is expected these vessels will make the run of 131 miles between Louisville and Cincinnati in six hours.

Steam will be generated in eight flue boilers. It has not been decided whether single engines of 30-inch diameter and 10-foot stroke or compound engines will be used.

Great Lakes Plant Gets Contract for Construction of 605 Foot Freighter

The Wilson Transit Company of Cleveland, Ohio, has placed an order with the Great Lakes Engineering Works, of Ecorse, Michigan, for a bulk freighter of the arch type construction. The vessel is to be 605 feet over all length, with 60 feet beam and 32 feet molded depth. She will be driven by a triple expansion engine with cylinders 34½, 40 and 65 inches diameter and 42-inch stroke.

Steam will be supplied by three Scotch boilers, 11 feet by 13 feet 6 inches. The ship will carry 12,500 long tons on 20-foot draft. Delivery is scheduled for the middle of September.

New Steamer Contracted for by Benton Transit Company for Lake Trade

The Chicago Steamer Exchange has contracted for a new steamship for the Benton Transit Company, of Benton Harbor, Mich., which will enter the lake trade this summer. The steamer, building at East Booth Bay, Maine, will be in service by June 1.

She will be 152 feet long, 30 feet wide, provide berths for 100 passengers, and have a freight capacity of 350 tons.

All the machinery is being furnished by manufacturers of Lake Michigan ports. The boat will have a steel turtle-shaped deck forward and command the lowest insurance rate.

Babcock & Wilcox Company Earns $9.29 a Share in 1921

The annual report of the Babcock & Wilcox Company, for 1921, shows net income after charges, Federal taxes and inventory adjustments of $1,394,589, equivalent to $9.29 a share earned on the 15,000 shares of capital stock outstanding, compared with net income of $2,207,803, or at the rate of $14.71 a share in the preceding year.

Gross profit totaled $2,101,061, against $4,281,866 in 1920.

Construction of Ten to Fifteen Self Propelled Oil Carriers for South American Service Contemplated

Four to Six Million Dollars May Be Expended for Special Type of Steel Ship—Preparation of Plans Believed to Be in Preliminary Stages

THE possibility of the placing of an order for the construction of from 10 to 15 self-propelled steel oil tankers of a specialized type, at a total cost which it is believed will range from four to six million dollars, is the latest new ship construction prospect for 1922, according to information obtained by MARINE ENGINEERING AND SHIPPING AGE.

It is learned that the New England Oil Refining Company, 25 Broadway, New York City, is contemplating the construction of such boats for service between Maracaibo Lake and other Venezuelan ports and possibly Tampico or other oil centers of Mexico. While no definite or detailed information was obtainable with regard to the present status of these contemplated ships, it is reported that a prominent New York naval architect has been consulted with a view to preparing tentative plans of a type of vessel suitable for such service.

It is thought that the proposed carriers will be about 350 feet in length and to meet the requirements they would probably have a draft of 10 or 11 feet in order to make the passage to and from Maracaibo Lake. The propelling machinery will very likely consist of internal combustion engines developing from approximately 800 to 1,000 horsepower, giving the vessels a speed of 8 or 9 knots.

Many Contracts Being Placed for Leviathan Equipment

The work of reconditioning the steamship *Leviathan*, which will involve a total expenditure of $8,200,000, is well under way at the plant of the Newport News Shipbuilding and Dry Dock Company, Newport News, Va.

Among the contracts for materials and equipment, which have been placed by the shipbuilding company in conjunction with the *Leviathan* contract, the following are included to date:

For steel plates and shapes, gyro compass equipment, insulated safety wire, copper pipe, main electric generator, tubes for auxiliary condenser, aero fire alarm system, monel metal bars, brackets, fans, air pressure gauge, forged steel flanges, torsion meters, tubes for drainage condenser, fuel oil meters, forced draft blowers, hardware, electric lighting fixtures, electric clock cases, plumbing fixtures, fire hose, fuel oil burners, pumps, donkey boiler, and iron and steel pipe.

City of Tampa, Fla., to Vote May 23 on $600,000 Port Bonds

The ordinance officially calling a city election for May 23, for voting on $600,000 bonds for completion of the municipal port terminals, has been passed by the city commission of Tampa, Fla. The ordinance provides for the issuance and sale of bonds, for the expenditure and disbursing of the funds from the sale of the bonds, and calls the election to authorize the same. It provides that when sold, the money be used for building municipal docks or wharves, railroad tracks, warehouses, etc., on the west side of the Ybor estuary, and any money left shall be used only for further improvement and development of the harbor, and the city's waterfront property.

City Manager Hall's estimates include the following: Two thousand four hundred thirty-five lineal feet concrete docks and bulkhead at $175 per foot, $426,125; freight warehouse, one-story, $70,000; cranes, trucks, etc., for loading and unloading, $40,000; water supply, office building and other expense, $30,000; total, $566,125.

Aberthaw Construction Company Gets $271,416 Job on Portland Pier

The contract for the construction of the substructure of the State pier at Portland, Me., was awarded on March 10 to the Aberthaw Construction Co., of Chelsea, Mass., on the company's tender of a price of $271,416.75.

Initial development calls for a pier 1,000 feet in length, 144 feet in width at its outer end, 236 feet in width at its inner end with the dock between the proposed pier and Atlantic Wharf to be 250 feet in width. The berth adjoining the pier will be dredged to a depth of 35 feet at mean low water for a width of 125 feet and the berth adjoining the Atlantic Wharf to a depth of 30 feet, gradually deepening to 35 feet at the property line. The plans and specifications were prepared by Fay, Spofford and Thorndike, of Boston, Mass., consulting engineers.

It is expected that the pier will be in operation early in 1923.

Creole Awarded to Robins Plant for Reconditioning

The contract for the reconditioning and conversion of the Southern Pacific steamship *Creole* from coal to oil burning was forwarded on April 11 to the Robins plant of the Todd Shipyards Corporation, Brooklyn, N. Y. Besides the conversion of the fuel system the work includes the rearrangement of boilers, reconditioning of passenger accommodations and the building of additional passenger quarters at a total cost of close to $200,000.

Big Dredging Job Proposed for Delaware River

United States Engineer Office, Room 815 Witherspoon Building, Philadelphia, will receive sealed proposals until 12 o'clock noon, May 18, for dredging in the Delaware River on the Liston Range.

The work to be done consists of the construction of a channel having a least bottom width of 800 feet, a least depth of 35 feet at mean low water and a length of approximately 7,000 feet. The estimated quantity of material to be removed, including allowable overdepth, is 1,476,600 cubic yards, scow measurement.

Baltimore to Spend $50,000,000 For Development of Its Port Facilities; $10,000,000 of Fund Authorized

THE Port Development Commission of Baltimore, Maryland, after several months' work, has made public the tentative plans for the proposed development of the Baltimore port. The total port loan amounts to a sum of $50,000,000.

The Public Improvement Commission now has $2,200,000 available for immediate use in the development of the harbor. With the cooperation of the Improvement Commission, the Port Commission will have the use of this sum at its command. Ten million dollars of the total sum of $50,000,000 has already been authorized and as soon as leases are made will be available. When the leases are made a part of this loan can be used to replace amounts advanced by the Public Improvement Commission. Thus a revolving fund will be kept intact for working capital and the Port Commission would be able to immediately begin the improvements in accordance with the plans.

TENTATIVE PLANS

At the northern extremity of the bulkhead will be a long marginal wharf and south of this a series of five piers.

Tentative developments for the eastern side of the harbor show eight piers on the Canton Company's property, but the policy of the commission is to expend its principal efforts on the western side of the river. If lessees should be found for piers on the Canton Company's property, piers will be built in accordance with the layout plans, after the property for them is acquired by the city.

The city owns a big block of property on McComas Street and it is proposed to concentrate there first. Other property will have to be acquired in order to carry out the commission's plan. All the waterfront on the south side of Locust Point, from the Western Maryland piers at Port Covington to Fort McHenry, will be required for the carrying out of the McComas Street project. Practically two whole blocks of this site are owned by the Baltimore and Ohio and the Bethlehem Shipbuilding Corporation, Bethlemem, Pa.

PATAPSCO DEVELOPMENT

It will be necessary to confine the channel of the Patapsco River where it overflows the mud islands and flats to the south shore and also to acquire property owned by Arundel Corporation or compensate them for practical loss of waterfrontage, in order to carry out the plan for the Patapsco group on the mud islands behind Hanover Street bridge and the proposed fill in front of the bridge. The layout as planned cuts off the Arundel property entirely from development for pier purposes.

Marine Construction News of the Month

Ship Contracts — New Ship Concerns and Shipyard Improvements—Terminal Projects—Government Contracts

SHIPS AND SHIPBUILDING

Ship Purchase, Seattle, Wash.—Alaska Steamship Company, Seattle, Wash., is in the market for purchase of a passenger and freight ship for service between Seattle and Alaskan ports. Intention to build apparently abandoned. Three thousand ton ship probably needed.

Repair Contract, New Orleans, La.—Repairs to damage to Standard Oil Company's tanker Pioneer, caused by collision with seawall at Tampa, Fla., awarded Jahncke Dry Dock Company, New Orleans. Repairs: Installing new stem, fairing of vessel's forefoot, renewing 24 plates on bow, drydocking and painting.

Fireboat, West Coast.—New York naval architect understood to be preparing tentative plans and specifications for fireboat for a city on west coast. It is believed proposed boat will be about 125 feet long with Diesel engines, 600 indicated horsepower, and capacity of 10,000 gallons per minute. Estimated cost is $300,000.

New Ferry, New York.—Report in New York marine circles that West Shore Railroad is considering construction of new ferryboat developed that while new boat had been contemplated time of definite action is not certain.

Steel Ferry, British Columbia.—Canadian National Railways Grand Trunk Pacific Dry Dock, Prince Rupert, B. C., reported as having secured order from British Columbia Public Works for steel ferry to operate on Francois Lake about 250 miles inland along Grand Trunk Pacific Railway, boat to be fabricated and assembled at plant and shipped to lake for completion. Contract includes construction of wooden cradle to be built on marine ways and installed by Public Works Department.

New Ship, Welland, Ont.—Collingwood Shipbuilding Company, Collingwood, Ont., received order from National Sand & Materials Company of Welland, Ont., of which David Dick, Jr., is president, for special type steamship for securing and carrying sand and gravel. The vessel will be about 258 feet long, deadweight carrying capacity of 3,000 tons, single screw, driven by triple expansion surface condensing steam engine with two boilers having 180 pounds working pressure.

Oil Burner, Los Angeles, Cal.—Clyde's sailing ship Falls, formerly operated by the Matson Navigation Company, in run from San Francisco to Philippines and Hawaii, will be converted into oil barge, operating out of Los Angeles harbor.

Recondition Steamers, San Francisco, Cal.—Thomas L. Wand and Wellesley, steam schooners purchased by John C. Ogden, to be reconditioned at San Francisco, will probably be equipped with Diesel engines and other changes made before they are placed in coastwise lumber trade.

Construction Contract, New York.—Tebo yacht plant of Todd Shipyards Corporation was awarded contract for construction of steel Diesel-engined yacht to be built to designs of Cox & Stevens for Merrill B. Mills, of Detroit. Dimensions: 129 feet over all length, 23 feet beam; two Diesel type, six-cylinder, four-cycle Winton engines, each developing 225 brake horsepower.

Pile Driver Hull, Tampa, Fla.—The Tampa Shipbuilding and Engineering Company of Tampa, Fla., with price of $4,500, was low bidder for pile driver hull for United States District Engineer office at Montgomery, Ala., at opening of bids in that office on March 20.

Construction Contract, Wilmington, Del.—The Bethlehem Shipbuilding Corporation, Ltd., was awarded the contract for construction of an ocean-going auxiliary yacht for Keith Spalding, of Chicago. Delivery scheduled for first of October, 1922; vessel 161 feet long, designed by Henry J. Gielow, Inc.

Fireboat Conversion, Portland, Ore.—City of Portland, Ore., C. A. Bigelow, Commissioner of Public Affairs, is investigating feasibility of converting its oil burning steam fireboats into Diesel or gasoline equipment. City maintains two fireboats: one, 125 feet long, capacity of 9,000 gallons per minute; the other, 115 feet long, capacity, 6,000 gallons per minute.

Contract Award, New York.—G. E. Engineering Company, 449 West 42nd St., New York, was awarded contract for steam supply system, specification 4586—Bureau Yards and Docks, Navy Department, Washington, D. C., price $168,300 (150 days) less $86,100 (30 days), item 6 (deduction made if two 250 horsepower boilers are furnished by Government), making total award of $71,300 (120 days).

Diesel Engine Installation.—Announcement made from Seattle that Pioneer Towing Company, engaged in Puget Sound—British Columbia, towing for years and now enlarging operations in Sound log towing industry, has converted one of its tugs into Diesel-powered vessel and will make similar installation in another boat of same type.

Construction Contract, West Virginia.—Contract for construction of steel side wheel car ferry for use on Mississippi River awarded to Charles E. Ward Engineering Company, of Charleston, W. Va. Boat is for Missouri & Illinois Railroad, designed by Cox & Stevens, naval architects, 25 Broadway, New York. Dimensions, 285 feet long, beam 86 feet, draft 5 feet.

Seagoing Dredges.—Latest developments regarding proposed building of six seagoing dredges, estimated cost $4,500,000, indicate the project is receiving serious attention of United States Engineer Office, Washington, D. C., and according to present plans, four of six proposed boats will be equipped with Diesel electric machinery, remaining two to be steam driven. Department also working on preparation of designs for steam driven dredge of somewhat smaller dimensions than 247-footers already proposed.

Repair Contract Award, New Orleans, La.—F. W. Hooley Iron Works, New Orleans, awarded contract for repairs to Shipping Board steamer Youngstown.

Contract Awards, New Orleans, La.—Johnson Iron Works, Dry Dock & Shipbuilding Company, Inc., New Orleans, La., was awarded three jobs for repairing and general overhauling on steamships Tegucigalpa, Ceiba and Yoro, of Vacarro Bros. & Company Lines. All three vessels were docked, scraped, painted, tail shafts drawn, and pintles examined, along with numerous other repairs.

Coastwise Towing Job.—W. G. Coyle Towing Company of New Orleans, La., contracted with J. W. Sullivan of New York, to tow from New Orleans to Jacksonville, Fla., Ferris type wooden ship Abergfoil, to be converted into barge. The new ocean going tug DeBardelebem, formerly Bartherry, was scheduled for towing job. Same company reported as engaging with Sullivan concern to tow the steel barge Nashville from New Orleans to New York, to be used in Long Island Sound service.

Reversing Rudder Installation, Bridgeport, Conn.—McNab Company of Bridgeport, Conn., delivered to Hildebrant Dry Dock Company, South Rondout, N. Y., one of their Kitchen's Patent Reversing Rudders, measuring 66 inches by 77 inches, for installation on 70-foot tow boat building at Hildebrant yard to order of Transmarine Corporation. The tow boat will be driven by 170 brake horsepower Nelseco Diesel, six-cylinder submarine engine, non-reverse type.

Possible Construction of Oil Carriers, New York.—New England Oil Refining Company, 25 Broadway, New York, contemplating construction of from 10 to 15 self-propelled steel oil tankers of specialized type, total cost ranging from four to six million dollars. Dimensions: 350 feet long and probably a draft of 10 or 11 feet.

Contract Award, New York.—Bethlehem Shipbuilding Corporation, with bid of $157,680, awarded contract for reconditioning steamship Granite State for service in United States Lines. Contract provides increasing cabin accommodations, installation of accommodations for about 400 third-class passengers in rooms.

To Construct Steel Barge, Algiers, La.—Johnson Iron Works, Algiers, La., awarded contract for construction of all steel oil barge for Southern Paper Mills Corporation, Moss Point, Miss. Dimensions: 144 feet long, 32 feet beam.

Ship Construction, Boston, Mass.—It is learned that the North Atlantic & Western Steamship Company, Boston, Mass. (Nawsco Line), contemplates addition of six motorships to fleet, type similar to American motorship William Penn, apparently held in high favor.

Possible Construction.—Old Dominion Steamship Company is said to be considering building two new passenger and freight ships, coastwise type.

Repair Contract, Mobile, Ala.—Alabama Dry Dock Company awarded steamship Bayo Chicago repairs, work consisting of repairing bow damaged in collision with steamship Antinous. Also awarded contract for repairs on steamship Trinidadian, tanker of Gulf Refining Company.

Contract Awards, Hoboken, N. J.—W. & A. Fletcher Company, Hoboken, N. J., awarded contracts for Eastern Craig, Benjamin Brewster, San Pablo and Sixaolo, drydocking and various repairs. Total about $7,900.

Shipping Board Contracts.—Steamers McKeesport and Bremerton awarded Federal Shipbuilding Company for repairs; McKeesport, $7,899, and Bremerton, $6,238.

Keel Laying, Alameda, Cal.—Alameda plant of Bethlehem Shipbuilding Corporation laid keel for 20,000-ton ore carrier, April 15, beginning of work on first of two steamers on West Coast.

Contract Awards.—Bethlehem Shipbuilding Corporation awarded steamer Eastern Sea, $6,097; Chappaqua, $1,246. Curtis Bay Copper and Iron Company also received award from Shipping Board of the West Gotomska for repairs, at $7,377.

Motor Craft.—Six 50-foot motorboats being built at Navy Yard, Norfolk, Va., competition with Mare Island, probably be completed by July 1, contingent on promptness of delivery of five engines from Portsmouth, N. H. Engine for one of boats arrived and wood necessary in construction of boats received from New York. Receipt makes possible trying out of first boat at early date. Probable cost of boats, $16,000 each.

Steamship to Be Repaired.—The Mazama, damaged by Lewis Luckenbach, drydocked at Sun Shipyard for miscellaneous repairs.

To Be Reconditioned.—Shipping Board steamship Egremont, laid up some time, taken over by Kerr Steamship Company, now at Newport News Shipbuilding and Dry Dock Company's yards for repairs. Upon completion, soon, to be taken to New York and placed in service between that port, Norfolk, and India.

Repair Contract.—Contract for repairs to steamer Heffron awarded by Shipping Board to Robins Dry Dock & Repair Co., price $11,000.

SHIPYARDS AND DRY DOCKS

Shipyard Sold.—Maryland Dry Dock Company took over operation of plant of Globe Shipbuilding and Dry Dock Company, April 1.

Shipyard Restored.—Winnisimmet Marine Railway and Shipyard restored to activity after period of idleness, with hauling out of Ransom B. Fuller, of Eastern Steamship Lines. Winnisimmet yard, one of marine projects of war, situated on Marginal St., Chelsea, Mass., Railway, built at cost of $600,000, can haul large draft ships.

Shipyard Bought.—Plant of Beaumont Dry Dock and Shipbuilding Co., one of largest in Texas, purchased by Petroleum Iron Works Co. New owners to transform plant into one for building fabricated vessels, steel oil tanks and railroad rolling stock, probable actual operation this month. Plant erected during war, turned out many vessels during that time. Complete in every detail, considered one of largest plants of kind in that section of country. Petroleum Iron Works Co. will enlarge plant, make other improvements not in deal. Said that company has contracts already for hundreds tons of steel for steel tanks in this country and Mexico.

PORT IMPROVEMENTS

Seawall, Anona, Fla.—Contract for constructing seawall at Haven Beach awarded to A. T. Le Vasconte.

Pier, Biloxi, Miss.—Plans submitted to Chamber of Commerce for building amusement pier; J. H. Etter interested in building.

River Terminals, Memphis.—City plans construction of river terminals and warehouse. Issue $150,000 bonds. Address Rowlett Paine, mayor.

Harbor Development.—Broward County Commissioners, Fort Lauderdale, Fla., to construct ocean inlet, deepen local harbor, $100,000 bonds voted.

Inlet, Jetties, Etc.—Jupiter Inlet, District Palm Beach County, Fla., to construct inlet, jetties, deepen water way; approximate cost $80,000 to $100,000.

Seawall, West Palm Beach, Fla.—D. E. O'Hara received contract from Palm Beach Company, $30,000, to construct concrete seawall at El Cid, C. H. Ruggles, engineer.

Levee.—Four mile levee to protect Carter Lake District and East Omaha land, planned by Pottawattami County, Ia. (Council Bluffs), and Douglas County, Neb. (Omaha), $175,000.

Seawall.—Contract awarded Burns Dredging Co., Sarasota, Fla., to build 3,700 foot seawall around Cedar Point, reclaiming 22 acres; approximate cost of seawall $50,000, dredging $26,000.

Wharves.—City of Orange, Tex., has sold $240,000 bond issue for construction of 800 feet additional wharves, modern warehouses, and various other improvements. Address the mayor.

Loading Facilities.—Humble Oil & Refining Co., Houston, Tex., reported planning construction of loading station, skeleton wharves, and probably two storage tanks at mouth of Neches River, Texas.

Levee.—Red River, Atchafayala and Bayou Boueff Levee Board awarded contract to H. Devill & Co., Marksville, Miss., to construct 57,000 cubic yards levee in island district between Alexandria and Boyce, price $13,000.

Wharf Dock.—Contract awarded by District Commissioners, 509 District Building, Washington, D. C., to Cambridge Manufacturing Company, Cambridge, Maryland, for wharf dock at Water St., between M and N streets, price $14,260.

Harbor Improvements, Houston, Tex.—Thomas H. Ball, chairman of Harbor Board, reports $1,000,000 may be available next 12 months for ship channel development; project calling for 10-foot channel, 60 feet wide from turning basin to foot of Main street.

Contract Award.—Contract for pile foundations of new Norfolk grain elevator awarded by City Port Commission to Sanford & Brooks, Norfolk, price $92,941.30. Foundation will require nearly 3,000 piles; includes in specifications cofferdam, $14,000, and excavating expense, $12,500.

Levee, Clarksdale, Miss.—Proposed construction of 21 miles of levee, extending from Brunswick to point opposite Vicksburg, approved by Yazoo Mississippi Delta Levee Commissioners; estimated cost $1,500,000, reclaiming about 250,000 acres land in Sharkey, Holmes, Leflore, Yazoo and Humphrey counties.

Pier Contract Award.—City of Philadelphia, Department of Wharves, Docks and Ferries, awarded contract for construction, with appurtenant work, of superstructure, Porter Street Pier, No. 84 South Delaware River, to Franklin M. Harris & Co., 1518 Parrish St., Philadelphia, Pa., price $1,674,515. Superstructure to be two-story steel and reinforced concrete structure.

Warehouse and Superstructure, Havana, Cuba.—Havana Docks Corporation, Havana, Cuba, awarded Turner Construction Company, 224 Madison Ave., New York, contract for construction of 5-story warehouse and 2-story superstructure on pier in Havana harbor. Pier is 580 feet long and job runs into several millions of dollars.

Dredging, Delaware River.—United States Engineer Office, Room 815, Witherspoon Building, Philadelphia, to receive sealed proposals until 12 o'clock noon, May 18, for dredging in Delaware River on Liston Range. Work consists of construction of channel having least bottom width 800 feet, least depth 35 feet at mean low water and a length approximately 7,000 feet. Estimated quantity of material to be removed, including allowable overdepth, is 1,476,000 cubic yards, scow measurement.

Harbor Improvement, Beverly, Mass.—Beverly, Mass., to get $98,000 additional in schedule for new river and harbor improvements for widening and deepening the channel and improving harbor conditions. Schedule calls for estimated expenditure of approximately $31,100,000 authorized under bill ordered reported by House Rivers and Harbors Committee in Congress. Bill provides only for new projects and, if enacted, would require subsequent passage of appropriation bill providing funds for various projects. Besides the Government appropriation, city has already appropriated $25,000 and State has made $50,000 available for work.

NEW INCORPORATIONS

It is reported from Richmond, Va., that the Newport News Shipbuilding and Drydock Company has increased its capital from $12,000,000 to $26,000,000.

Ocean Carriers Co., Manhattan, $35,000; J. L. Watson, F. H. Butehorn, T. E. Halle (attorney, F. J. Knorr, Albany).

Florida Dredging Company, Miami, Fla., capital $75,000; C. L. Crandall, president, B. K. Crowell, secretary and treasurer.

A. D. N. Steamship Corp., Manhattan, $15,000; R. J. Sykes, M. Roger, W. H. Gillon (attorney, P. Boyninge, 111 Broadway).

Gore & Hanley, Manhattan, navigation, $5,000; A. G. Gore, W. Hanley, W. Ostrander (attorney, P. Baumer, 15 Whitehall St.).

Megathlin & Clark Dredging Co., Miami, Fla., capital $50,000; J. L. Megathlin, president, J. T. Rambler, secretary and treasurer.

Murray Harbor Transportation Co., Brooklyn, $150,000; J. J. Murray, T. J. Boyce, J. D. Carroll (attorney, J. P. Carroll, 189 Montague St., Brooklyn).

Gladding Express Co., Steamship Line, Baltimore, Md., Pier 4, Light St., increased capital to $100,000; establish steamer service between Baltimore and Cambridge.

Nidaros Steamship Company, 605 Water St., Baltimore, Md., capital $200,000; E. Garrett Atkinson, 105 Singer Ave., August Olsen and O. Legard Jones, incorporators.

Consolidated Fuel Company of New Orleans, La., organized for purpose of bunkering ocean-going ships and tow boats. Company will have following officers: H. C. McCormack, president; Robert P. Hyans, vice-president; H. C. Whiteman, vice-president, and Charles Harrington, sales manager.

Floridian Trading Corp., Steamship Line, Jacksonville, Fla., capital $150,000, chartered with Emory C. Meek, president; F. I. Maynard, secretary; E. K. Sharlow, treasurer; steamship lines to Havana, Cuba, Porto Rico and Venezuela ports.

FOREIGN ACTIVITIES

Launching of Steamer, Hamburg.—Built for the Deutsche-Australische Dampfschiffs Gesellschaft, steamer Cassel, 9,000 tons, has been launched from Kockum shipyard at Malmo.

Motor Shipbuilding in 1921, Holland.—Of total of about 500 large and small craft built in Holland during 1921, nearly 70 vessels under 500 tons were propelled by internal-combustion machinery.

Order for Ten Steamers, Russia.—Russian Soviet Government has given order to newly opened Anglo-Baltic Shipbuilding and Engineering Company, at Reval, for ten steamers, work to begin at once.

Order for Floating Dock, Rotterdam.—The Rotterdamsche Droogdock Maatschappij has placed order with Burgerhout Engineering and Shipbuilding Co., Rotterdam, for construction of 8,000-ton floating dock.

Delivery of Tugboat, Rotterdam.—Tugboat Schiedam, built by Messrs. J. and K. Smit, at Kinderdijk, Holland, for Messrs. L. Smit and Co.'s Sleepdienst, Rotterdam, just delivered to owners. Fitted to burn oil fuel or coal, the vessel has a length of 71 feet, breadth of 19 feet, and depth of 9 feet 9 inches.

Proposed Ship Construction, Australia.—The State Government of Western Australia propose construction of Diesel engined ships of 4,000 tons for conveyance of approximately 2,500 tons of frozen meat in addition to other cargo and approximately 175 passengers. Vessels to be built in Scotland, but probably not until headway is made with scheme to establish new harbor and rail center on King's Sound, Western Australia.

Ship Completion Work, Belgium.—Work resumed on Red Star passenger liner Belgenland, designed for Antwerp trade, passenger capacity of 3,000, to register 26,000 tons. She is largest ship to ply in Belgian waters. At time of war she was turned into transport with no passenger accommodations. Her maiden voyage is contemplated in spring, 1923. Built by Harland & Wolff, the ship is 670 feet long, 75 feet wide, speed 18 knots.

Biggest Motorship Proposed, Germany.—In addition to 9,000-ton cargo vessel now being built for North German Lloyd's, equipped with machinery of 3,200 horsepower, Norddeutscher Lloyd have under consideration construction of intermediate cargo ship, 9,000 tons gross, with speed of 12½ knots. The ship would perhaps be largest motor passenger liner in world, although Scandinavian-American Line intends to build an 18,000-ton ship of this class when circumstances become more propitious.

Ship Construction, Sweden.—Approximately 55,000 tons of shipping were launched from Swedish shipyards during 1921, increase of 12,000 tons over previous year. On Jan. 1, 1920, vessels totalling over 100,000 tons were under construction. Motor ship rapidly gaining ground, however, in Scandinavia, no less than 42,530 tons of ships now nearing completion being of this type, compared with 12,220 tons of steamships. Total tonnage, Swedish mercantile marine, January 1 this year, estimated 1,090,000 tons, about 1.73 per cent of world's merchant shipping, decline of 55 per cent from 1914 figures.

May Build Six Vessels, England.—Anglo-Saxon Petroleum Co., London, has invited tenders for construction of one, three, and six motor vessels, 2,800 tons deadweight, 270 feet long, 46 feet 6 inches wide, 23 feet deep, and 17 foot draft, speed 10¾ knots. To be constructed for carriage of refined cargoes, propelled by single six-cylinder four-cycle Diesel engines. Deck auxiliaries and steering engine to be steam driven; large donkey boiler fitted in engine-room. Two steam driven cargo pumps, large size to be installed, and 8 inch double pipe lines fitted throughout cargo tanks.

Steamer Launching, England.—The Northumberland Shipbuilding Co., Ltd., launched from their shipyard at Howdon-on-Tyne the steamer Eastmoor, building to order of Messrs. Moor Line, Limited (Messrs. Walter Runciman & Co., Ltd.), Newcastle-on-Tyne, Thursday, March 30. She is shelter deck type, 415 feet long, 53 feet wide, 35½ feet molded depth, carrying about 9,250 tons deadweight on 26 feet 3 inches draft, built to Lloyd's highest class. Propelling machinery supplied by North Eastern Marine Engineering Co., Ltd., Wallsend-on-Tyne, consisting of set of triple expansion engines, three boilers of 180 pounds working pressure.

Philadelphia Pier Contracts Awarded Harris Company on Bid of $1,674,515

The City of Philadelphia, Department of Wharves, Docks and Ferries, has awarded the contract for the construction, with appurtenant work, of the superstructure of Porter Street Pier, No. 84 South, Delaware River, to Franklin M. Harris & Company, 1518 Parrish St., Philadelphia, Pa., at a price of $1,674,515. The superstructure will be a two-story steel and reinforced concrete structure. The contract was awarded on March 27, bids being as follows:

Franklin M. Harris & Company, Philadelphia, Pa.	$1,674,515
J. S. Rogers Company, Philadelphia, Pa.	1,730,400
Triest Contracting Corporation, New York City	1,794,080
Hughes - Foulkrod, Philadelphia, Pa.	1,798,450
Frederick Snare Corporation, Philadelphia, Pa.	1,828,400

BUSINESS NOTES

The Air Reduction Sales Co., New York, recently acquired all the assets including the patents, trade marks, and trade names of the Davis-Bournonville Co., Jersey City, N. J. The consolidation brings together two large companies, whose histories have, to a great extent, been the history of the development of the oxy-acetylene welding and cutting industry. The Air Reduction Sales Company is a pioneer in the extraction of gases from the air for industrial use. The Davis-Bournonville Company was organized in 1907. The equipment in the future will be marketed under the trade name of Airco-Davis-Bournonville.

Calvin P. Moon, who has been actively engaged in the shipbuilding industry on the Atlantic seaboard and abroad for many years, has established an office in the Cunard Building, 25 Broadway, New York City, to engage in the business of marine engineering, reports, surveys, and designs for ships.

The firm of Wunsch & TerKuile, recently organized, has an office and warehouse at 302-4 McDougal Street, Brooklyn, N. Y. This organization is a co-partnership of Messrs. J. W. Wunsch and C. V. TerKuile and will act as the selling agents for manufacturers of material-handling machinery and marine equipment.

The Marine Decking & Supply Company has removed its New York office from 44 Water Street to 3 Coenties Slip. Mr. A. B. Jewell is in charge of the New York territory on the tackle block division.

STEAMSHIP INTERESTS

The *Maryland*, built at the Tebo plant of Todd Shipyards Corporation for account of Maryland Pilots' Association, assigned to Cape Henry, Maryland, Station. Trial trip very successful. Vessel has berths for 15 pilots, and left New York for Baltimore on April 12.

Ocean Carriers' Co., Inc., 25 Beaver St., New York, announced new freight service, New York to Portugal and Spain, with fleet of chartered steamships. Service inaugurated April 25, followed by other vessels at regular intervals.

Australia will resume trade with Germany on August 1, ending period of seven years during which embargo on trade with enemy countries was enforced.

Beginning this month monthly cargo service to South and East African ports will be inaugurated. New service under management of Mallory Steamship Lines, Inc., only American line operating on route, and will involve placing six vessels on route. Calls to be made at Cape Town, Port Elizabeth, East London, Durban, Beira and possibly Zanzibar and Mombasa.

TRADE PUBLICATIONS

Safety Hand Lamp.—A patent electric safety hand lamp, suitable for use in any danger zone, as aboard oil tankers, is described in a bulletin issued by Watts, Fincham & Company, Ltd., Billiter Building, 22 Billiter St., London, E. C. 3, England. The lamp is gas and watertight and has been approved by Lloyd's Registry of Shipping.

Oil Storage.—The recent issue of *The Atlantic Lubricator,* published by the Atlantic Refining Company, Philadelphia, Pa., contains an illustrated feature article on the design, construction and erection of steel oil storage tanks as well as a number of articles dealing with lubricating and oil producing problems.

Hand Cut Files.—A catalogue listing the various type quality files produced by Murcott & Campbell, Inc., Brooklyn, N. Y., is being distributed. Standard types of pillar and flat files, mill saw files, square and round files, half round, etc., with illustrations and details of numerous special types are given together with sizes and prices. The various "cuts" in general use, as rough, bastard, second cut, smooth, dead smooth and the like are described for the information of those desiring to adopt files best suited to their requirements. Sections of files used to the greatest extent are also shown

London Steam Turbine.—For driving boiler feed pumps and standard types of centrifugal machinery, the London steam turbine has been developed in two bearing units. The application and advantages of this system of drive have been described in a preliminary folder distributed by the London Steam Turbine Company, Troy, N. Y. Complete details of the equipment will be given in a new catalogue which will be published within a short time.

Evaporators for Boiler Feed Water.—The application of evaporators to the purification of boiler feed water by distillation is covered in a general and non-technical manner in bulletin No. 360 now being distributed by the Griscom-Russell Company, New York. This booklet is so written that the application of Reilly self-scaling evaporators to the power plant for the elimination of scale, blow-down, priming, and the like may be readily understood by the executive as well as the engineer.

Export Helps.—The Department of Commerce, Bureau of Foreign and Domestic Commerce, has issued a booklet outlining the organization and purpose of the new industrial machinery division of the bureau. Every manufacturer who has surplus products which can be exported is recommended to use the service of the new division in extending his foreign business. The research work of the division is extensive and as time goes on will be the source of practically any information that may be required of the selling possibilities of all manner of machine products in the world market.

WE GUARANTEE that of this issue 5,650 copies were printed; that of these copies 4,195 were mailed to regular paid subscribers, 346 were provided for counter and news company sales, 211 were mailed to advertisers, 27 were mailed to employees and correspondents and 871 were provided for new subscriptions, copies lost in the mail and office use; that the total copies printed this year to date were 33,000—an average of 5,500 copies a month.

MARINE ENGINEERING AND SHIPPING AGE is a member of the Associated Business Papers, Inc. (A. B. P.), National Association of Periodical Publishers, Inc., New York Business Publishers' Association and the Audit Bureau of Circulation (A. B. C.).

Requests for change of address should reach us two weeks before the date of the issue with which it is to go into effect. It is difficult, and often impossible, to supply back numbers to replace those undelivered through failure to send advance notice. In sending us change of address, please be sure to send us your old address as well as the new one.

An Appeal to Congress

SENATORS and Representatives, you are about to decide whether or not America is to have a merchant marine.

The situation is this; with the exception of the four freighters recently purchased by Captain Robert Dollar, there is not a privately owned American vessel operating in the trans-Pacific trade between America and Asia. Captain Dollar with all his experience is in doubt as to whether he can successfully operate his new ships but he is going to do his best. If Captain Dollar does succeed in making a go of his American ships under existing conditions, it will be largely because he is a trader as well as a shipowner. He can send his vessels out filled with lumber from his own mills. When one of his vessels lacks a return cargo he purchases copra or some other commodity for his own account and, still further, he runs a feeder service for 1,600 miles up the Yangtze River. Captain Dollar with his large resources might be able to mix a few American vessels with the ships that he operates under foreign flags but without some inducement from the Government, the Pacific Ocean, which is destined to become the center of the world's commerce, will remain bare of privately owned American ships.

Turning to the Atlantic, we find that with the exception of the passenger and cargo ships operated by the United American Lines and the International Mercantile Marine Company there are very few *privately* owned American vessels in the transatlantic trade. Take away the vessels owned by the Shipping Board, the vessels owned by the companies which carry their own products, such as the Standard Oil, United States Steel and United Fruit, and our merchant marine today is no farther ahead than it was in 1914.

This is an appalling situation. The Shipping Board is maintaining today about 70 services covering every trade route known to be of any value but it is doing it at a tremendous cost to the Government. Without the direct and indirect aids proposed by the President, or some equivalent, the Government will be compelled to operate these routes or see them abandoned. The two years that have elapsed since the passage of the Jones Act have demonstrated that, unless some reasonable degree of national aid is assured, private initiative and private capital cannot be interested in these routes which are necessary to protect our overseas trade.

After all, it is the foreign trade in which the country is primarily interested. American ships are but one of the means for promoting this trade but no one can gainsay that the farmers, manufacturers and merchants of this country will receive far more loyal, regular and expeditious service from American ships than they will from the vessels of a country which is our competitor in trade and our possible enemy in war. Every great maritime country in history has spared neither effort nor expense to secure the carriage of the greater part of its sea-borne commerce in its own ships manned by its own men for in no other way can it be certain of the delivery of its goods or of protection in war.

Higher construction costs, higher operating expenses, the probable disposition that will be made of the Shipping Board vessels, together with the experience and established banking, insurance, and merchandising facilities possessed by our competitors have prevented private capital from investing in shipping. These factors will continue to prevent the private ownership of American vessels until capital is assured that Congress will provide reasonable aid until such a time as our shipping is established on a sound and permanent basis.

The enactment of the Shipping Bill which the President has recommended for your consideration will assure the reestablishment of our merchant marine and the retirement of the Government from the ship operating business, which will change the Shipping Board vessels from a liability to an asset. We cannot go on as we are for it is impossible for the managers of Government-owned vessels to feel the same interests or assume the same responsibilities that they would in their own vessels. On the other hand, there is an inherent fear on the part of business men against doing any

American Marine Association Backs Shipping Bill

WHEREAS, the American Marine Association is an organization composed of concerns and individuals identified with the building, repairing and operation of ships and the manufacture of those things with which ships are equipped, and therefore vitally interested in any movement which makes for a real American merchant marine; and

WHEREAS, the President of the United States, both before and since his election, has emphasized the necessity for an ample merchant marine and pledged the country to that end insofar as it lay within his power to so do; and

WHEREAS, following a recent message from the President urging early action, there were introduced in the Congress two bills, designated S 3217 and HR 10644 respectively, both designed to provide legislation which will make it possible for merchant ships flying the American flag to both successfully compete with foreign owned vessels and insure to America the maximum of trade with foreign countries so vital to the welfare of the whole nation; and

WHEREAS, the said bills S 3217 and HR 10644 are based on recommendations of the United States Shipping Board made after exhaustive studies of ways and means of building and perpetuating a merchant marine that will best serve America's interests, be it

RESOLVED, that the American Marine Association hereby endorses bills S 3217 and HR 10644 now before the Congress of the United States and urges their early passage.

FURTHER RESOLVED, that the Secretary be and hereby is instructed to send a copy of this Resolution to each and every member of the Congress, to the press and to such other individuals and organizations as should be informed of our action.

business with an organization that savors of Government ownership.

Gentlemen of Congress, you are about to pass a tariff bill designed to protect the manufacturer and the farmer. Can you consistently refuse to grant to the merchant marine the same form of protection that has developed our other industries?

Marine Insurance Rates

"THE three great elements which constitute the fabric of Foreign Commerce," said Mr. Charles R. Page of the Firemen's Fund Insurance Company in his address before the Ninth National Foreign Trade Convention, "are ocean transportation, marine insurance and banking credits."

In discussing the factors upon which marine insurance rates are based Mr. Page pointed out that "it is perfectly obvious that the operator of the American ship cannot successfully compete for cargo as against the foreign ship, if the shipper must bear increased costs for shipment by American vessels. It is also true that in the past underwriters generally have maintained differentials, not against American ships, as such, but against Shipping Board owned and operated tonnage. For this alleged discrimination it is the underwriter's belief that there has existed ample justification.

"Happily, however, these conditions are passing. The Shipping Board has very wisely called practical shipping men into its service. It has cut the number of its operating agents in half and has retired from active service all but the best of its ships. This is rapidly bringing about the elimination of the differentials against Shipping Board vessels, as such, and has laid the foundation for a cooperative effort between the board and the underwriters to establish parities of rating with competitive lines so far as may, upon impartial investigation, be justified by facts.

"American cargo underwriters stand ready to do their part in the development of American lines and to grant to our ships equal rates for equal conditions of management and tonnage, and equal record of immunity from disaster. They cannot, however, be justly asked to grant equality of rating, if the record shows physical inferiority of tonnage, or inefficiency and inexperience of management, or records of mishaps that overshadow like records of the operations of their competitors. Neither can any other scheme which is calculated artificially to equalize or sweep away disabilities that actually exist, and which ignores sound economic principles established by actual experience, be in the long run other than detrimental to the establishment of our merchant marine on a sound and lasting basis."

In the above statements Mr. Page has given a very important reason for the immediate passage of the Shipping Bill for a differential in marine insurance rates might easily become a greater handicap than the lack of a subsidy. The Government aid proposed in this bill or its equivalent must be obtained, if private operators are to be induced to take over the Shipping Board vessels. The longer the Government is compelled to operate the trade routes that the Jones Law requires where the operating expenses are paid by the board, the more demoralized and inefficient will become the officers, the crews and the managements. The inevitable result of continued Government operation will bring about such a state of inefficiency that the majority of American operators will never be able successfully to operate American privately owned ships on a businesslike basis.

Why Handicap Common Ownership of Cargo and Vessel?

THE exclusion of American vessels from the benefits of the Shipping Bill where there is common ownership of vessel and cargo unless one-third of the capacity of the ships is available for common carriage for ten days preceding sailing dates is wrong in principle and cannot possibly result in a saving to the nation.

It is quite true that the United States Steel Corporation and the Standard Oil Company can easily exist without a subsidy from the Government but neither of those companies nor the Government itself can change fundamental economic laws. The fact that the cost of operation of a vessel varies directly as the cost of living in the country whose flag it flies is not influenced by the wealth or poverty of a vessel owner ought to be evident.

Of course a powerful concern supported by its domestic

Society of Naval Architects and Marine Engineers Indorses the Shipping Bill

RESOLVED, that the Society of Naval Architects and Marine Engineers, at a special meeting held in New York on May 19, 1922, having discussed the bill now pending before the Congress of the United States, known as "A Bill to Amend and Supplement the Merchant Marine Act, 1920, and for other purposes" desires to go on record as heartily favoring the early enactment of this measure into Law.

This Society considers it of vital importance that our country place itself in a position to carry its surplus products to competitive foreign markets in ships owned in America and of American registry, as a matter of prudence and economy in time of peace and as a measure of national defense in time of war.

Be it further resolved that a copy of these resolutions be forwarded to the President of the United States and to the Senate and House Committee having jurisdiction of the pending measure.

business could continue to run its ships under the American flag but it would have to sell its products in foreign markets in competition with goods carried in cheaper ships which could only mean that the difference would have to be made up in the price paid by the domestic consumer. If the "private owner" is to be discriminated against in the forthcoming legislation, it is to be hoped that he will retain his vessels under the American flag without the public being compelled to pay an excessive indirect subsidy.

But there is more probability that these large concerns, and almost a certainty that the smaller concerns, will consider it the better way to transfer their vessels to a foreign flag. If they did, it would mean, in oil tankers alone, a loss to our merchant marine of approximately 40 percent of the privately owned tonnage.

To permit this tonnage to pass out of our hands is to admit that the merchant marine is of no importance as a naval auxiliary; for what could the Navy do, or the greater part of our merchant ships for that matter, without an assured supply of oil fuel? Is it not, with the American people, more a question of an adequate merchant marine than a case of nullifying the efforts of those who have set the example which we all hope America will follow, which is to carry its own products in its own delivery wagons?

A Wise Decision

THE decision of President Harding to let the *Leviathan* remain the *Leviathan* is to be commended. The war name of this famous vessel that carried thousands of American soldiers to and from the battlefields of France should never be changed. Doughboys all over the country will watch its career as the finest passenger ship afloat and the sentiment and pride that they hold for the great ship which was their home through the dangerous submarine zone should be respected.

West of the Appalachian mountain range the *Leviathan* is probably the only American passenger ship that is universally known. Those who travel to Europe from Middle West towns will want to tell their friends when they return that they sailed at least one way on the famous *Leviathan*. Her name, like any well-known trade name, will have a distinct advertising value not only for herself but for the whole American merchant marine.

But the *Leviathan* cannot maintain an express passenger service alone. The White Star Line and the Cunard Line have three giant express steamers each. Why not show the world that America can build a passenger ship that will be second to none and let that vessel take the name of the man under whose administration the American merchant marine will be reestablished—President Harding?

History's Greatest Industrial Achievement

WITH the delivery of the 535-foot passenger and cargo ship *Western World* to the Shipping Board on May 9, not only the greatest shipbuilding program but also the largest industrial achievement in the history of the world was completed. The Shipping Board has been the butt for acrimonious criticism of all sorts; it has been accused of scandalous inefficiency but little has been said of its accomplishments for which the future is bound to give it credit.

Since the *North Bend* was turned over to the Government on May 24, 1917, the board has constructed 2,312 vessels of many different types and of 13,636,711 deadweight tons. These vessels, if placed in a straight line, stem to stern, would extend for a distance of 158 miles and, if steaming a mile and a quarter apart, would reach from New York to Southampton, England. The total deadweight tonnage is equal to the carrying capacity of 388,363 freight cars loaded 35 tons per car.

A still more striking comparison may be made of the power generated by the propelling machinery. Colonel W. P. Wooten, Corps of Engineers, U. S. A., figured that the development of the Great Lakes-St. Lawrence Waterway would deliver 1,464,000 horsepower at the switchboard. The total power that could be developed by the vessels constructed by the board is 4,593,000 indicated horsepower or over three times the amount that we could expect from the St. Lawrence.

To construct this enormous tonnage with adequate shipbuilding facilities would have been a big task but at the beginning of the program there were only 50,000 first class

mechanics available in our shipbuilding industry. It was necessary to expand this number by intensive training to 385,000 men proficient in the trade of building ships. It was necessary to give aid financially and otherwise to 179 yards for plant construction and again it was necessary in carrying out this stupendous project to build 13 marine railways, 17 floating docks and 2 graving docks.

The result of this shipbuilding program has been obscured by the impossibility of efficiently operating vessels under Government ownership but nevertheless our increased share in the carrying trade of the world has been the means of marketing billions of dollars worth of our products when ships were scarce. In 1914 commodities to the value of $368,359,756 were carried in our own ships representing 9.7 percent of our water-borne foreign trade whereas in the fiscal year beginning June 30, 1920, this percentage was increased to 44.8 percent and the value of the imports and exports carried in American bottoms amounted to $5,071,905,981.

Of course no one will challenge the fact that the board and its agencies hold a record for building ships that never has and probably never will be equalled but how many realize what a tremendous industrial undertaking it was? How many realize the daily decisions involving millions and sometimes hundreds of millions that had to be made? How many know that the board had to take the duties and responsibilities of a banker, to become a general contractor providing shipbuilding facilities, to become a manufacturer, increasing the output of ship equipment, to become a lumber merchant, acquiring timber forests, to become an insurance company selling protection? How many know that it built and operated street railways, constructed and operated hotels for housing workmen, homes for the families of workmen, in fact whole towns with paving, water, gas, sewers, theatres and hospitals? Those who know this and the many other things that the board and its agencies accomplished will acknowledge and history will record that the greatest shipbuilding program was also the greatest industrial project.

The Hague Rules

ONE of the important subjects of vital interest to all branches of the maritime industry which was discussed at the Ninth National Foreign Trade Convention was *The Hague Rules*. As everyone knows, every nation has different laws relating to ocean carriers. In our own country the regulations printed on the bills of lading issued by our steamship companies are so long and complicated that it not only takes a long time to read them but they are beyond the understanding of the ordinary man. In addition to this, every steamship company has its own form and some of them several forms which are subject to change overnight. This has caused constant friction between the shipper and the carrier because the shipper has never understood his rights and where losses have occurred the shipper has in practically every case found that he has no right of recovery.

"An International Code is needed," said Mr. Charles S. Haight, in addressing the convention, "because so long as the law remains different in every country, you cannot standardize your forms, nor correct the evils which exist today. Even where changes are admittedly needed, no one nation will act alone, if by so doing its own shipowners will be placed at a disadvantage. As in our Disarmament Conference, all must act together, or no one will act at all."

These rules, which were drafted at The Hague last August by a committee composed of shippers, shipowners, underwriters and bankers, are really a codification of our own Harter Act with three important additions: First, they increase the carrier's liability from $100 to £100 per package; second, they allow the shipper twelve months to present any claim for damage and to bring suit; third, they shift the burden of proof, in cases of pilferage and several other kinds of losses, from the shipper to the carrier, requiring the carrier to prove that the loss did not occur through the fault of himself or his employers.

According to Mr. Haight, these rules if universally adopted will benefit the shipowner, the cargo underwriter and the banker as well as the shipper. The shipowner will be benefited because he will not have to face the complications of different laws in every country, the present irritation will be removed and all carriers will be affected alike. The cargo underwriter will be able to fix his rates with definite reference to known risks and the banker will have a safer bill of lading and, by making the collateral safe, business will inevitably be facilitated.

It is a remarkable thing that the principal opposition to the rules in this country comes from the Chicago packers. The packers want the carriers to be responsible for each package up to its market value and they also want to make them responsible for errors in navigation or in the management of the ship. To do so, would of course cause the freight rate on every package to be determined by its value rather than by its size or weight. This would cause endless confusion and prevent the adoption of a set of rules which would have worldwide uniformity.

However, as Mr. Haight stated, "the rules are actually in force in Europe today. All of the great lines of the North Atlantic Conference are issuing bills of lading governed by the rules to shippers of cargo moving to the United States. The American shipper, however, cannot receive the benefit of the rules until the Harter Act has been changed. Under the law, it is provided that a carrier who issues a bill of lading in violation of the Act shall be subject to a fine of $2,000 for each bill issued. Even though the points of conflict between The Hague Rules and the Harter Act are of comparatively little importance, a carrier cannot be asked to incur the risk of such a penalty by issuing a bill of lading in this country which is in conflict with the Act."

For the information of our readers, a bill has been introduced in Congress which is a short enabling act; it provides that a bill of lading under The Hague Rules shall be lawful, any provision in our statutes to the contrary notwithstanding.

A summer meeting of the Institution of Naval Architects of London, England, will be held in Paris, France, July 4 to 8 inclusive. Papers will be read on the mornings of July 4, 5 and 6, the afternoons being devoted to sightseeing, receptions and visits to industrial works.

Ship Subsidy Is a "Trade Subsidy"

Marketing Our Excess Products of Farm, Mine and Factory Is Basic Object for American Merchant Marine

By "Old Scotch"

PRESIDENT HARDING has but recently been quoted in the daily press as saying that the merchant marine problem is perhaps the greatest confronting his Administration and that, if the proposed legislation—that is, the pending Subsidy Bill—fails of passage, the retrogression of the United States as a great nation may be expected to follow without fail.

In all of his many patriotic utterances, no greater nor more vital truth has ever been expounded. That is the very essence of this entire subject. The hearings thus far have, singularly enough, been far afield from the point at issue. All the testimony and discussion have been confined to the restricted phases of the proposed legislation. Wages of seamen, sale prices of ships, building costs, operating expenses, etc. are all relatively minor subjects compared with the great underlying principle involved in this pending legislation. One of the contemporaneous writers on the subject rightly used a term in a recent article, which seems to fit the subject admirably. It is not a "Ship Subsidy," said he, but in reality a "Trade Subsidy" for the United States.

What a Merchant Marine Is For

The basic object of a merchant marine for America is not the mere possession and operation of ships as common carriers for the whole maritime world, such as England's for example, but for the marketing of our excess products of the farm, mine and factory. We have no aspirations, either expressed or implied, for conducting a merchant marine as a basic industry, as we have already a sufficient diversity of occupations to keep our citizens well employed without going afar on the oceans of the world to seek business of that kind. All we want and need at this time is to round out and develop our existing industrial enterprises by providing, under our own flag and direction, every function which goes toward a complete system. We must treat all the industries of the United States as one great undertaking of which the people of this country are the stockholders. No industrial enterprise of any description can be said to be complete, unless it owns and controls its own delivery systems.

So far as our national enterprises are concerned, we are an isolated community with the great oceans surrounding us. The foreign trade which we have with contiguous territory, served by railroads and other land means of conveyance, is negligible compared with what we should and do have with countries reached only by ocean highways. If we do not have the vehicles for delivery of our goods over these ocean highways, we cannot, in times of keen competition, represented by normal world conditions, expect to transact our business of selling in competitive markets across the seas. The very people we must compete with own their own ships or delivery systems and it is fatuous for us to delude ourselves into thinking for a moment that they will carry our own goods at such rates or in such manner that we will be able to sell our goods in these competitive markets.

If we do not have any foreign trade and can consume all we produce here, there will not be any need for our having ships at all, except a sufficient number to act as auxiliaries for the national defense. But no one claims that we do not have to engage in foreign trade to dispose of our surplusage of goods. It is so elementary a fact that all recognize it. Why then should there be any controversy whatever over the necessity for having our own means for delivering these goods to our customers? The only reason the American people need a merchant marine at all is in connection with the disposal of our national productions, hence why argue over the fact that the Government, for the best interests of all concerned, must by some such means as proposed in this subsidy bill make up the difference in the cost of operation of the ships by our own people?

A Mistaken Conception

Some editorials in supposedly American papers have had the hardihood to re-announce that moth-eaten dictum, that it is not a good economic policy to build up one industry at the cost of others. Such propaganda is the most veritable buncombe. We are not attempting to build up an industry, as such, but merely providing proper and necessary facilities to conduct all our other industries. All avocations share in the benefits of shipping alike. The number of people who would be employed in building and operating a sufficient fleet of vessels to conduct our American ocean-carrying business is entirely negligible when compared with any other of our great basic industries.

The necessary number, comparatively small as they may be, who will engage in shipbuilding and ship operation, must be American citizens and, as such, are entitled to just as good living conditions as all other citizens who use the same degree of skill in their various callings, and no better. To attain that standard of living in a trade primarily of national importance, these people must compete in a wide open field of endeavor with all the people of the world at large. No other American industry has to be thus handicapped, and people engaged in shipping and its allied industries have an inherent right to be placed on an equality of opportunity with all other branches of industry in this country.

Enormous Increase of Our Export Trade

Under the direct operation of steamship lines, or delivery systems, through the medium of the vessels belonging to the United States Shipping Board our export trade has increased enormously over conditions which existed in pre-war times, or would have been obtained if we did not have these ships in operation at this time. True they are now being operated at a loss to the Government of approximately four million dollars per month. Place it at $50,000,000 per year and what is that compared with a foreign trade amounting, even now in a period of great depression, to three or more billions of dollars annually? Does any one imagine for a moment that, if the United States had had no ships of its own at the time the armistice was signed, we would have exported anything like the immense amount of goods abroad we have sold in the last four years? Is there, or can there be, any better demonstration that the money lost in ship operation is a "trade subsidy" rather than a "ship subsidy?"

No shipowner is going to grow rich, if this subsidy bill is enacted, as the terms of the bill will so regulate it that but fair returns may be received by Americans who operate the ships to help our trade. Any industry must be operated at some profit, or who would be found to engage in it for glory alone?

Why Our Tankers Should Be Protected by Subsidies

Some criticisms have been indulged in by opponents of the bill that great concerns, such as the Standard Oil companies

which own and operate their own ships, would be benefited under the terms of the bill. Why shouldn't they be benefited? There are but a very few commodities, which our modern living methods demand, more essential to our peace, comfort and protection than petroleum and its products. A world wide battle is now being waged among the great nations for control of this highly essential fuel. Nationally we are doing nothing to protect the interests of the American people, despite the fact that foreign governments are doing everything possible to gain control of the undeveloped oil-bearing areas which yet remain. It has been predicted by numerous well-informed writers that in another decade we Americans, to satisfy our unsatiable demand for gasoline and other petroleum products, will be buying them from our principal competitor for world eminence. The only organizations which stand between us and such a condition are our great and powerful oil companies. They should, therefore, be protected and encouraged in every legitimate manner by the Government.

What of it, if they should make large sums of money? Any citizen, at all provident, can invest his savings in the shares of these companies and partake of any profits they can make. Unless such organizations can make money, they will not be able to compete with foreign companies aided by foreign governments in obtaining new oil lands. If their ships engaged in carrying oil cannot be operated successfully under the American flag, they quite naturally will be transferred to alien flags and employ aliens at the lower wages to which they are accustomed. We would lose not only the money paid to their crews, which at best is a small matter, but we would lose a great national asset. Wars nowadays are as dependent upon petroleum as they are upon explosives and without an enormous fleet of oil carriers under the American flag we would be in a sad predicament. It must be kept in mind that every oil tanker under our flag is a national asset for defense of the nation. The small amounts proposed to be paid to their owners, as prescribed in the subsidy bill, will barely be sufficient to make up the difference in the cost of operation under the American flag. By all means there should be no restrictions placed upon them by the Government, such as compelling them to offer one-third of their tank space to the public, as proposed in the bill.

Therefore, Mr. Congressman and Mr. Senator, who will soon be called upon to vote on this bill, do not let petty political prejudices interfere with your good judgment. Consider this measure as the great broad national question, which it undoubtedly is, and do not let it ever escape your consideration that its passage will not only make national prosperity possible and probable in times of peace, but that in addition it will add greatly to our safety in time of war when we cannot borrow the equipment of our rivals to fight our battles on the sea, land and air.

Established English Liner Companies Were Able to Make Good Showing in 1921

A STUDY of the reports of the net profits of nine important passenger and freight-carrying English liner companies for the years 1920 and 1921 would indicate that the financial position of the best known companies is nowhere near as bad as the gloomy reports that we have received would make it appear.

In the subjoining table of the profits of these companies and their allocation, it is to be noted that, except where otherwise stated, the profits are shown net after deduction had been made for depreciation, taxation, sinking fund, directors' fees and auditors' remuneration. The net profits for 1921 were 87 percent of those for 1920 and the amounts paid out for dividends were as much as 90 percent of those similarly distributed in 1920. The average rate of dividend, however, ranged from 12.3 to 17.9 percent less. The ratio of profits earned to capital invested, which for these companies is about £15,692,000, was 11.4 percent for 1920 and 10 percent for 1921.

As a further optimistic indication, the report of the Cunard Steamship Company, which is not included in the table, shows that that company made more money in 1921 than it did in 1920.

That shipping investments in Great Britain, when securities are offered by sound financial companies, are received with popular favor is shown by the fact that the Peninsular and Oriental Steam Navigation Company was able to float £3,500,000 of 5½ percent debentures about the middle of March. The issue was over subscribed in less than an hour. The Lamport and Holt Company was also able to float a similar issue for £2,000,000 a week later.

Joint Hearings on Shipping Bill Concluded

Chairman Greene Says Lengthy Examination Breaks Record for Consideration Given Any Bill That He Can Remember

THE joint hearings on the Merchant Marine Act of 1922, which closed on May 19, are remarkable from many angles. The amount of information included in the voluminous records of these hearings is enormous. Anyone who will take the trouble to procure and study them will be assured of a liberal education on shipping and shipbuilding matters.

Outside, however, of the expert testimony presented by the leading shipowners, operators, builders and marine authorities, the hearings were distinctly different from those on former bills designed to aid shipping in the interest shown by commercial and industrial organizations. The endorsements of the President's plan that were received from such organizations in the South and the Middle West are ample proof of the fact that the interest in an American merchant marine is no longer confined to the seaboard. Of particular significance was the endorsement of the American Farm Bureau, and the testimony of Mr. J. R. Howard, its president, before the joint committee.

Ships Control Trade

"Ships, in the last analysis, are nothing but the delivery wagons of trade," said Mr. Howard. "The nation which controls these delivery wagons controls a service which produces satisfied customers, increased orders, and an ever-widening circle of prestige. If the other nation controls the ships which carry our products, we shall never be able to reach the markets when the price is best. The other nation will use the ships then; we may when he does not want to.

"The British are today furnishing a service from New York to Brazil. This service is slow, requiring about 14 days, and taken care of by old boats. We can hardly expect better service than this to carry our typewriters, harvesters, plows and a thousand and one other articles to South America unless we do it ourselves. The speed is held down to the service afforded from Great Britain. We shall never build up a fast, satisfactory service on British third or fourth rate vessels. Yet it is upon this fast service which develops rapid mail communication that trade depends and the illustration of the service between United States and South America might be multiplied in other directions. We cannot rely upon others to give the service necessary to build up this trade. If it is to be done, America must do it herself and I am sure we all want it done."

> *"It is an old statement that 'Trade follows the flag.' If we would have an increasing export trade we must create a condition, through legislation, which will give the American shipowner such encouragement and such feeling of confidence and stability in his business, that he can develop all the facilities surrounding the successful operation of our shipping to a point where he can offer to our shippers all the advantages which they might secure through other channels."*—F. R. Todd, vice-president John Deere Company.

Why the Farm Bureau Believes the United States Needs a Merchant Marine

Mr. Howard called attention to the following reasons for an American merchant marine:

"1. The United States is no longer a debtor but rather a creditor nation and must seek the business.

"2. Other nations will be competing in Europe where we market our goods. We must be prepared to put our products into the European market promptly and cheaply.

"3. Transportation, the servant of business, must be available when needed; it will be available only if we control the ships.

"4. The service afforded by foreign-owned vessels is second rate, hampers our exports and makes impossible proper increase of our overseas business. * * *

"Finally, in shipping, as in any other business, the real profit depends upon the volume handled. There is no need for me to tell you that when the available cargo is doubled, the profit may be multiplied not twice but 4 or 5 and even 10 times, or a large deficit converted into a substantial profit. But American ships are infants in the game, and must be aided until they become strong.

"The subsidy, as stated in my telegram to the President, stands on the same footing as the tariff. It is a protection for a weak industry. It is justifiable only when the industry is young. We support a ship subsidy because it is necessary for the growth of the business. When that need is past we are opposed to it.

"The subsidy to be effective must do two things: (1) It must meet the difference in operating costs; (2) it must aid in building up a large volume of traffic. * * *

The Value of Ship Subsidy to the Farmer

"What is the interest of the farmer in this? He sells his grain at the local elevator, his live stock at the nearest primary market, and cotton to the local factor, and his fruit to a jobber or broker. What interest, I say, has he in a merchant marine? The farmer had a vital interest in securing the best possible market price for his products. It has been said so many times that I hardly need to repeat it here that the price of grain is made at Liverpool. It follows that he is interested in the delivery wagon which takes his grain to Great Britain. For a number of years cotton exports have represented practically the entire surplus of American exports over imports. During the season 1921 there were exported from the United States and Canada (and most of the Canadian exports come from America) 2,445,501 barrels and 2,722,327 bushels of apples. Is not the apple farmer decidedly interested in the availability of service which will make it possible for him to dispose of his surplus profitably, and while our exports of live stock are negligible, still our exports of meat and live-stock products are one of the most important in the whole list of American exports. The interest of the farmers is very great in these delivery wagons. The farmer in 1921 exported more than $1,976,000,000 of raw agricultural products; of finished and unfinished agricultural products there were $867,000,000. In addition, the farmer is vitally interested in the welfare of his customers in this country, manufacturers, laborers, merchants, etc.

"I want to stress the advantage it is to the American manufacturer and labor, which indirectly is a very great benefit to the farmer.

"The farmer has a still more direct interest than this. He has organized his own grain-selling agency, his own cotton-

marketing organization, his own fruit-marketing organization. It is not only well within the bounds of possibility but it is very probable that these organizations whose primary object is scientific and orderly marketing will decide to arrange to handle these exports themselves. In such case the American farmer becomes the American shipowner, not because he is primarily interested in shipping but because of the necessity of disposing of his own products.

"We recognize the difficulty of converting this subsidy into units of agricultural products. However, if a 5,000 gross ton ship is loaded full of wheat destined to Europe, it has about 367,000 cubic feet of available cargo space. Wheat in bulk occupies 47 cubic feet per ton of 2,240 pounds. Dividing 367,000 by 47 we have 7,808 tons.

"Multiplying by 2,240 pounds per ton we have 17,489,920 pounds, or, at 60 pounds per bushel, we get 291,498 bushels. The subsidy for 3,000 miles, New York to Liverpool, is $750. Dividing the $750 by the amount of grain, the subsidy amounts to about one-quarter of a cent per bushel.

"Upon the same basis of 367,000 cubic feet of cargo space and 130 cubic feet per ton for cotton we can load 2,823 long tons of cotton in a 5,000-ton ship. This means 6,323,520 pounds, or, at 500 pounds per bale, 12,647 bales. Using $750 once more as the direct subsidy we find this means 5.93 cents per bale. From a southern port the distance would be a little greater, making the subsidy perhaps a cent per bale more. From Galveston it would be for 5,000 miles nearly 10 cents per bale.

"Obviously such a cost is entirely out of proportion to the benefits secured in a constant service available for the disposition of the surplus products. The amount of the subsidy to the boat is a little more than the marine insurance on grain and less than one-fourth of the insurance on cotton.

"I know that marine insurance varies with so many conditions as to make comparison difficult. But the rate quoted from Galveston to Liverpool on cotton in good steel steamers last Saturday was 1 9/16 percent of the value. With cotton selling at 18 cents per pound a bale is worth $90. Insurance then would be $1.408 per bale while subsidy would be 10 cents.

"Grain insurance runs 27½ cents per $100 value during summer months, and 37½ cents during winter months. At present prices at the seaboard this means 37½ cents insurance on 67 bushels or about 5½ mills per bushel in the winter and 4 mills in the summer. The subsidy, however, will be only about 2½ mills per bushel.

"Let us remember that marine insurance is a guaranty against loss from storm. The subsidy will be a guaranty against loss from failure to reach market regularly and when markets are best. Marketing is today the farmer's chief problem. The ship subsidy is our best insurance for orderly marketing of the farmer's exportable surplus."

> *"Several times in the past four or five years we have had shipments for South American ports bound on foreign vessels so split up as to make the first part of the cargo useless on arrival because parts of our machines would be left to come on a second boat and as our goods are threshing machinery we were too late for the season. While we can not, of course, prove that this was done by design and intentions to embarrass the sale of our goods, we feel perfectly sure of the fact and have yet to learn of this happening to our English competitors."*— Findley D. Mount, president Advance Rumeley Company.

Quality of the Opposition

In order that our readers may form their own opinion of the kind of testimony that was furnished by the three or four men who appeared in opposition to the Shipping Bill, we will now quote a few extracts from the *Record*. The first will be from the testimony of Benjamin C. Marsh, representing another organization of farmers.

"Mr. Edmonds. I understood before I came here this morning, Mr. Chairman, that the gentleman had made a remark about the President lending his help to an insidious campaign to rob the people of the United States. I would like for him to enlarge a little on that.

"Mr. Marsh. I didn't quite get your statement.

"Mr. Edmonds. I understand you made the statement this morning before I came here that the President was lending his help to an insidious campaign to rob the people of the United States.

"Mr. Marsh. Yes.

"Mr. Edmonds. Produce the proofs.

"Mr. Marsh. Produce the proofs? Hasn't the President urged the ship subsidy?

"Mr. Edmonds. That is no proof.

"Mr. Marsh. Now, I answered your question, will you answer mine?

"Mr. Edmonds. You answered with no proof.

"Mr. Marsh. Well, I deny that; I say it is.

"Mr. Edmonds. You may deny it. That is your thought. You have no right to make charges that you can not prove.

"Mr. Marsh. I am responsible to the folks that sent me here, not to any agent—not to any Philadelphia Congressman. I make that statement.

"Mr. Edmonds. You don't have to be responsible to me. I don't care who you are responsible to.

"Mr. Chindblom. Let me ask, Mr. Chairman, does the gentleman state that he had the privilege of coming here and making any remark that he pleases to make and not be responsible for it and not subject himself to cross-examination?

"Mr. Marsh. I am willing to be cross-examined.

"Mr. Chindblom. You are not showing that attitude now, sir.

"Mr. Marsh. I welcome it. Didn't the President indorse the subsidy bill?

"Mr. Chindblom. Yes.

"Mr. Marsh. And I denounce the subsidy bill as an insidious steal. If the President indorses the ship subsidy bill, I repeat that the President is indorsing an insidious steal to put over on the American people, and I am going to go all over the country saying that.

"Mr. Chindblom. Oh, well, that won't make much difference, you know.

"Mr. Marsh. Well, now, it may.

"Mr. Chindblom. But for a man to come here, Mr. Chairman, and deliberately offer an insult to the President of the United States and then say that he is not here for the purpose of answering questions put to him by a Philadelphia Congressman, I say is an outrage. * * *

"Mr. Edmonds. Of course, the gentleman airs a lot of views here, and he probably has his own opinion. So far as I am concerned, it doesn't affect me so very much because I know the gentleman's views and have known them for a number of years.

"Mr. Marsh. That is why I am so complimented that you are asking me questions.

"Mr. Edmonds. But you come here and because you happen to have a difference of opinion with the President of the United States, you have chosen to insult him before the committee. That is what I contend that you have done. The President has just as much right to his opinion on subsidies as you have, and if you have got any charges

to make that he is trying to rob the American people you ought to be able to prove them and you have not been able to prove them. I have not heard a particle of proof here in two hours.

"Now, you have made other charges here, you charged that Mr. Howard, the man who leads the real farm union in the United States—you have charged that Mr. Howard was in receipt of $100,000 a year from somebody or other, and that he was subsidized by other people and subsidized by a whole lot of people. Now bring your proof of that.

"MR. MARSH. Sure. * * * *

"MR. MARSH. Now let me correct a further statement. I said the Farm Bureau Federation gets money from the packers. That has been published widely and the fact proven in the farm press, and I say, if they didn't get money from the railway interests for selling the farmers out to the railroad interests in indorsing the Esch-Cummins law, they were miserably poor business men, and they are pretty clever business fellows.

"MR. CHINDBLOM. And of course that proves it, that they got the money, doesn't it?

"MR. MARSH. How is that?

"MR. CHINDBLOM. Your argument that, if they didn't get the money, then something else existed—that proves that they got the money?

"MR. MARSH. No.

"MR. CHINDBLOM. Then why say it?

"MR. MARSH. We are quite justified in making deductions. Do you mean to tell me that they would deliberately in cold blood massacre the farmers the way they did?

"MR. CHINDBLOM. Well, you are just throwing out suspicions and insinuations that everybody from the President of the United States down is corrupt because they disagree with you."

SHIPPING BOARD HONEYCOMBED WITH FOREIGN REPRESENTATIVES

"MR. EDMONDS. I don't want to ask Mr. Lasker. You say the Shipping Board is honeycombed with representatives of foreign governments; now say who they are. Mention their names.

"MR. MARSH. I won't mention any names.

"MR. EDMONDS. I want to get them just as much as you do.

"MR. MARSH. Ask Mr. Lasker and you will find out.

"MR. EDMONDS. I don't care to ask Mr. Lasker; I am asking you. You made the charge.

"MR. MARSH. I will make the charge and let Mr. Lasker disprove it if he can. If you want to know, ask Mr. Lasker; he won't tell me.

"MR. EDMONDS. You mean to tell me that you don't know any representatives of foreign governments in the Shipping Board?

"MR. MARSH. I don't want to go into details. I will be glad to try to get the information from Mr. Lasker. I will write and tell him the question.

"MR. EDMONDS. You deny then that you know who they are. You simply made the charge without any proof at all.

"MR. MARSH. If you want to put that interpretation on it, but if you want to know write Mr. Lasker and find out.

"MR. EDMONDS. If you know any, why don't you say so now. You have got the opportunity.

"MR. MARSH. I have not, but I am going to have a little later.

"MR. EDMONDS. I don't care anything about what you do later.

"MR. MARSH. I do.

"MR. EDMONDS. You simply make the charge here that the Shipping Board is honeycombed with the representatives of foreign governments. You have sent this out to your 600,000 members, yet you decline before a committee of Congress to say who these people are, and I want to know just as much as you do.

"MR. MARSH. I will let you know when I get ready.

"MR. EDMONDS. You are not going to let me know now because you don't know yourself. That is the reason, otherwise you would answer me.

"MR. MARSH. We have had set-tos before, Mr. Edmonds. You sneakingly tried to impugn my record during the war before the House Committee on Merchant Marine and Fisheries.

"MR. EDMONDS. I didn't ever need to impugn your record; everybody knows your record. Do you want it to go in here? I will put it in again if you want to."

STATEMENT OF MR. ANDREW FURUSETH

The statement of Mr. Furuseth, although in opposition to the Shipping Bill, was in reality an able defense of the Seaman's Act. Mr. Furuseth, who is reputed to have framed this Act, is president of the International Seamen's Union of America. He represents the unlicensed personnel which, according to his own testimony, contains only 18 percent of native-born Americans.

Mr. Furuseth's contention is that there is no real differential in operating expenses due to the wages of the crew on an American ship. But, note this quotation from his testimony: "Now, that there is a differential in other directions, I do not deny: and I said in my examination in chief that if, for other reasons, you want a subsidy or you think a subsidy is necessary, that is for you to judge: but please do not make a pack horse out of the crew to carry the responsibility for those injuries."

MARINE ENGINEERS ENDORSE BILL

The statement of William S. Brown, president of the National Marine Engineers' Beneficial Association, may be summed up in the following quotation:

"Wishing to take as little of the committee's time as possible, I will state in conclusion that it would seem that the proposed bill offers the probability, in the opinion of this association, of creating the adequate merchant marine so necessary to the Nation and, at the same time, will provide work for the marine engineers, thousands of whom are either unemployed at the present time or have been forced into other lines of endeavor; it will also provide work for men of the other branches of seafaring who are in a position similar to that of the engineers, and as a whole tend to alleviate the general unemployment situation, particularly affecting those trades involved in the building of ship construction, repairs, manufacture of supplies of various sorts, etc.

"With the passage of the measure this is probable, whereas if the measure does not pass it is absolutely certain that unemployment, especially in all branches of the marine field, will become more acute and the Nation as a whole will be in an even more difficult position than at present with regard to general prosperity and national defense."

NEPTUNE ASSOCIATION ENDORSES BILL

The Neptune Association of Licensed Masters and Mates of Ocean and Coastwise Steam Vessels, Incorporated, is in favor of the Shipping Bill. The Neptune Association is composed of approximately 7,000 licensed masters and deck officers.

"This association," said Mr. John F. Milliken, secretary-treasurer of the organization, "is in favor of the ship subsidy bill. Nearly all of the industries in the United States are protected by a tariff. We believe that it is vitally necessary for our country to have an adequate merchant marine, with legislative protection and Government assistance, to deliver the goods of our country in time of peace; to spread American doctrines and develop American business throughout the world, and to assist our Navy in time of war."

Prospects for American Shipbuilding*

Motorship Economy So Marked That Change to Diesel Machinery Will Rival Change from Sail to Steam

By J. L. Ackerson†

IN order to analyze the prospects for American shipbuilding it is necessary briefly to analyze in turn, first—world shipping, second—world shipbuilding, third—American shipping, and fourth—American shipbuilding.

It is possible to have a revival in world shipping and in world shipbuilding without any great increase either in American shipping or American shipbuilding.

World shipping depends upon international trade, which in turn is dependent upon the desire to exchange international products, the ability to finance this exchange of products, and the time necessary to insure the accomplishment of these two items.

The desire to exchange products, of course, exists. The necessity for this interchange of products also exists, not only on account of trade conditions, but also due to the fact that foreign countries are of necessity under the obligation of exporting goods in order to pay their respective debts.

Although the desire to exchange products exists, the ability to finance this exchange does not, at least for many of the European countries, exist. It is necessary that large credits be established in these countries to start their industries in the manufacture of exports.

Probably the only two countries that are in a position to finance this interchange of products are the United States and Great Britain. At the present moment, the financial interests of Great Britain appear willing to loan money for this purpose. In the United States, at the present moment there does not appear to be that same willingness. Just how long it will be before this will be brought about is uncertain; but probably the time necessary to crystallize public opinion, to effect the necessary loans, and following that to establish manufacturing on a post-war normal basis in the European countries, will be not less than three to five years.

Following this line of reasoning, it would appear to me that the world shipping will not return to what may be termed its normal proportions until this period of time, varying from three to five years, shall have elapsed.

World Shipbuilding

From the time this revival begins, an increased demand for ships will manifest itself. Whether new ships will be built or not as a result of this demand will depend upon two things, first, the tonnage necessary to carry out the increasing international trade; second, the tonnage actually existing at the time.

In viewing this, it should be remembered that on the whole there is no greater tonnage of vessels available today than would have been available today had the World War not taken place. Also, many of the ships now included in the world tonnage are old and obsolete. There have been few replacements of the better types of ships. The war tonnage, as a whole, cannot be regarded as a suitable and adequate increment to the merchant marine.

During the past eight years, comparatively few passenger vessels or combined cargo and passenger vessels, or even high grade cargo liners, have been added to the world tonnage.

The international trade revival that will unquestionably take place in the next three to five years will create a demand for vessels suitable for special trades, and also for passenger and combination passenger and cargo vessels.

These vessels when built will undoubtedly be built in accordance with the advances in engineering that have taken place in the past few years. Notable among these advances is the Diesel engine.

It would appear that when the demand for additional tonnage does manifest itself, the new tonnage required will at least be equal to the annual pre-war construction, possibly even greater.

American Shipbuilding

Although it can be shown with reasonable clearness that there will be a demand for additional world tonnage, it does not necessarily follow that there will be a demand for American tonnage.

American shipbuilding, of course, depends upon American shipping. An increase in American flag shipping depends upon, first, an increase in foreign trade shipping, second, upon the ability of American flag vessels to compete in this trade, and third, upon an increase in coastwise trade shipping. Relatively speaking, there have been, and probably will be, very few ships built in the United States for operation under foreign flags.

Increase in Foreign Trade

Although an increase in international shipping is certain, the question remains whether American operators can operate American flag vessels in competition in these trades with foreign flag vessels.

Several of the larger operating companies are now seriously making this experiment. Most of the ships that are being operated in carrying out this experiment are of special types, for example:

The United American Lines, one of the Harriman organizations, is operating the *Resolute* and the *Reliance* in the first class passenger service between the United States, United Kingdom and the Continent.

That line is also operating second and third class combination passenger and cargo vessels, the *Mount Carroll,* the *Mount Clinton,* and the *Mount Clay,* between the United States and the Continent.

The American-Hawaiian Steamship Company is operating large fast freight liners, the Diesel-engine ships *Californian* and *Missourian* between Pacific ports, Atlantic ports and European ports.

The United States Lines is operating first class passenger vessels between the United States and the United Kingdom.

It is yet too early to predict the results that can be obtained over any sustained period of time in these operations.

The success will probably depend, to a great extent, upon pending legislation. With favorable legislation it is probable that the results will be satisfactory, in which case there will undoubtedly be a decided demand for—

A—Passenger vessels
B—Combination liners
C—Special cargo liners

all for operation in foreign trade under the American flag.

These vessels of necessity will be built in the United States.

*Address delivered before National Foreign Trade Council Convention, Philadelphia, Pa., May 11, 1922.
†Vice-president Merchant Shipbuilding Corporation, Chester, Pa.

The coastwise trade has heretofore furnished the greater part of the merchant work that has been performed in American yards. This trade is increasing. Much of the trade that heretofore has been carried by rail is now being carried by water.

A great part of this carriage is done by special types of ships, as, for example, the Luckenbach ships, American-Hawaiian ships, Red D ships, and Agwi ships.

Many of the ships in these and other lines active in the domestic trade are old and obsolete. Undoubtedly there will be replacements in the respective types in the next few years. Many replacements are actually now in contemplation.

Competition in these trades will bring about a demand for more economical operation. This will be accomplished probably by obtaining new and special types; and by the conversion of existing ships.

Already there is much activity on the part of ship operators looking toward the building of new ships and the conversion of some of the more suitable of the Shipping Board ships.

Diesel Ships

Diesel ships deserve special consideration. Although there is no question regarding the exceptional economy to be obtained in the operation of these ships, American operators have been slow to adopt them.

The economy of operation is so startling that, in my opinion, the change from the present accepted type of machinery to Diesel machinery will make a change in shipping in the next decade which will be not unlike the change from sail to steam.

This change in the ships in future to be built will, in my opinion, extend not only to cargo vessels, but progressively will extend to passenger ships, first with the low powered twin screw passenger ships, and quite probably later to the larger powered ships.

The results, with which all are familiar, of the *William Penn*, which showed a saving of approximately $53,000 in one trip around the world, will inspire a number of operators to demand the same economy.

There will be comparatively few Navy ships built in the next few years. Navy building will be confined to airplane carriers, cruisers, scouts and submarines.

Conclusions

Summing up, it seems to me that the following conclusions are clear:

First—It will take from three to five years to stabilize international finances and to insure the establishment abroad of credits necessary to enable foreign industries to place themselves in a position to export large volumes of goods.

Second—During this period international trade will greatly increase until at the end of, say five years, it will attain what may then be termed its "normal."

Third—That during this period there will be an increased demand for ships. That this demand will cause to be culled from the present stock of unemployed ships those that are most suitable, and will then cause the building of new ships of the most suitable type, representing the advances in shipbuilding during the past several years.

Fourth—That this increase in international trade will bring about the desire on the part of American operators to engage in this trade.

Fifth—That this desire on the part of American operators will, if suitable shipping legislation is enacted, cause them to place contracts in American yards for new and special types of ships for operation under the American flag. That this demand for shipbuilding will be augmented by the demand on the part of American operators for special ships to be used in the coastwise and domestic trade. A part of this demand will be met by the conversion of existing American tonnage where practicable, but a part of it, however, will of necessity be provided by new ships, to be placed in American yards. An increasingly greater proportion of these ships will be equipped with Diesel engines of an approved type.

Sixth—A small demand will exist for naval auxiliaries, as outlined above.

This, then, is how I view the prospects of American shipbuilding—fair, but not alluring.

Operating Problems of the American Shipowner*

Wage and Subsistence Costs—Manning Requirements—Changes Recommended in Our Navigation Laws—The Ship Subsidy Bill

By Eugene E. O'Donnell†

NEVER before in maritime history have operators had to wrestle with the problems of so great a suddenly created merchant marine. In other nations the growth of shipping has been gradual. Here in America our gross register tonnage went up from 8,871,000 in 1917 to 18,282,000 in 1921. All of the amount of this increase was in ships designed for international commerce. Not only has our tonnage thus rapidly multiplied, but American owners and operators have been compelled to face, in most cases with little experience, the exigencies of strange new trade with the ports of distant foreign countries.

Except for the vessels acquired before the war, which in many cases were carefully designed for the work in hand, it cannot be said that the merchant marine as a whole is especially adapted to its particular requirements. The new fleet consists to altogether too great a degree of steamers of comparatively low speed and of the "tramp" order. We are lacking, of course, in swift passenger steamers, but we are lacking also in cargo steamers of the so-called liner type, which after all, if not the backbone of a merchant marine, is a class of ship of very great importance. This undeniably handicaps our owners and operators who contemplate the development of a cargo liner service, for vessels which have no reserve speed will necessarily find it difficult to maintain a regularity of service, especially in the trade like that of the winter months on the North Atlantic.

However, a considerable proportion of one-half of the steel tonnage of the Shipping Board which is characterized as good tonnage contains many ships fit for what may be described as the berth service to distant foreign ports, like the 7,800-deadweight-ton Hog Island ships, the 8,800-ton freighters and the larger shelter-deck and other steamers whose capacity in a few cases runs up to a maximum of 12,000 tons. Here is a fleet not to be despised in any survey of the world's shipping, and until we secure better steamers, these, outside of the "tramp" or bulk cargo service, must be regarded, together with the pre-war ships of the older com-

†Manager, Marine Department, C. H. Sprague & Son, Boston, Mass.

panies, as the main, active, operating backbone of our merchant marine.

Handicap of Wage and Subsistence Costs

First of the problems of American ship operators in this connection is the hard, undeniable fact that they have to pay more money for the wages and subsistence of their crews than do their European or Japanese competitors. American shipboard wages have historically been from 30 to 40 percent above British shipboard wages, and it is estimated at the present time that British wages are about 15 percent above Scandinavian. This is a handicap which in my judgment, and I believe in the judgment of virtually all practical owners and operators, can be overcome only by national assistance.

A great deal is being carelessly said about the higher "efficiency" and "economy" of American officers and men. It is not to be denied that many years ago, in the heyday of our wooden-built merchant marine, there was a higher efficiency in American ocean ships than elsewhere, generally speaking. But it must not be forgotten that this was an efficiency that had gradually been attained through many years of effort and experience.
